"The act of 1890 is by no means socialistic in character, as the permission to municipalities to build houses for working people and operate them on their own account would seem at first glance to indicate. The consent of the local government board is an essential preliminary to this form of activity. Efforts to dispose of the land to private parties or to building companies must first, in every instance, be made.

"This law is a sanitary measure rather than an enactment to encourage the erection of houses for working people. The only provision for the latter is that permitting the loan of money at a low rate of interest, upon security which is unquestionable, to trading and manufacturing companies employing persons of the working class. In this respect it differs materially in general characteristics from legislation on the continent, particularly in Belgium. The law is distinctly a measure of protection and only incidentally one of social advance. The moral to be derived from its considera-

tion is that an expensive awakening must come sooner or later to all communities where fundamental sanitary requisites in dwelling construction have been neglected. This legislation gives evidence that the interests of property will not henceforth be considered paramount to those of human life."

The last sentence we hope gives the keynote of all future legislation everywhere. The sacredness of property and the violability of humanity has, it appears, had its day—and the converse proposition is more to the front nowadays—and such questions as why should the producers be compelled to live in hovels while the speculators live in palaces, why the one should have to put up with a ten cent lunch while the other can spend thousand of dollars on a banquet are now agitating men's minds.

A rose is as sweet called by whatever name—so we will not cavil with our author about whether these movements of protecting those not able to protect themselves are called "measures of protection and only incidentally one of Social Advance"—or whether it is a measure of social advance and necessarily, therefore, one of protection.

The result is the same; greater happiness for humanity.

The author then enters into the subject of objections to expropriation; which means *the taking property out of one's possession*. It seems to be taken for granted that the taking of property from its holder by the state for the public good is a legitmate operation, which leaves only economic objections such as its cost, and what becomes of the dispossessed.

Property when taken by a City for its own use should be able to become as good a paying investment as private property, if judiciously and honestly handled; for, notwithstanding that it has to pay ten per cent more for compulsory condemnation, it should be able by the magnitude of its operations to recoup itself for this—and get a reasonable income from it.

"In estimating the cost of any improvement scheme, account should always be taken of the fact that the first cost will ultimately be reduced by the taxes upon the increased values of property on expropriated territory and in the immediate neighborhood."

In regard to what becomes of the dispossessed, that is those who are occupying the condemned buildings, it requires only a little management to prevent any serious inconvenience to them, *e. g.*, by proceeding by degrees rather than attempting everything at once. In a large undertaking doing only part at a time and when that portion is done provision is made for housing a large number of the dispossessed and part of the remainder may be destroyed and so on until all is completed.

"It would be futile to deny that large expropriations have resulted in overcrowding side streets in the vicinity. This fact is incontestably proved by the experience of Paris in piercing the city with her magnificent boulevards and in the enormous displacements which took place in London during the construction of the Victoria enbankment and the new law courts. There are other instances, however, to show that comparatively large works may be conducted without this unfortunate feature where sufficient care is taken, and work proceeds more slowly.

In Paris there is no compulsory provision for housing displaced people as in London; consequently there has been tremendous overcrowding of side streets along the great boulevards which were run through old and insanitary quarters."

The author next looks at "some results of expropriation" especially as exemplified in the chief cities of Great Britain where it has been used—in Edinboro, Dundee, Newcastle, Liverpool, Birmingham and Glasgow.

Expropriation has been not always done for rebuilding purposes but for providing open spaces in overcrowded districts as the following:

"Occasionally condemned houses have been purchased by the corporation and pulled down in order to give freer air to crowded neighborhoods. Such houses, instead of being purchased at prices favorable to the owners, have been bought by the corporation as uninhabitable buildings. Not a little of the expropriated insanitary property in Edinburgh has been turned into small open spaces. These can by no means becalled parks or squares, as they cover simply the space formerly occupied by one, two, or three houses. The spaces are paved over, supplied with light gymastic apparatus, and used as a recreation ground for children. Such thoughtful provision for the youth of tenement districts is a splendid boon. Small areas of this kind serve ethical as well as hygienic ends."

It cannot but be interesting in these days of municipal reform to give Glasgow's experience in this matter and its results, as Glasgow is the city of all others at the present time looked to as an example of successful municipal government in a monetary sense:

"In 1846 the municipal and police governments of Glasgow were consolidated. Shortly afterwards the city council determined to spend about £30,000 ($145,995) in acquiring property in the wynds and closes abutting on High street, in the Saltmarket, and in Gorbals. A fairly large area was thus purchased, but it was soon seen that in default of a proper building law builders would continue to consttuct the same kind of buildings in more modern quarters. The whole question of sanitary legislation and building regulations was then brought up, and after a committee had investigated the condition of English cities, which they found in superior sanitary condition, they made recommendations looking towards wiser sanitary administration for the city. Two of the most important recommendations were the appointment of a competent medical officer of health and a staff of nuisance inspectors for the prevention of overcrowding and the interdiction of houses unfit for human habitation. In 1862 an act largely embodying the recommendations of this committee received the sanction of Parlament. Its provisions were deemed at that time exceptionally rigid, and the period of operation was limited to five years. In 1866, however, when the application for the renewal was made, not only were the old parts confirmed, but modifications in the way of improvement were added. The reports of the health committee in relation to the insanitary state of the older houses of the city, coming at a time when projects of construction of railway terminals were pressing for solution, determined the town council, in 1865, to apply to Parliment for a city improvement act, whose object, as stated in the title, was "the construction of new and the widening of older and dividing of existing streets, and for other purposes.'

"The scheme, as originally conceived, embraced about 88 acres, with an average population of 583 per acre, though in some districts more than one thousand were huddled to-

gether in this space. The average rate of mortality was 38.64 per 1,000, and the deaths from epidemic diseases 36 per cent of the whole. Sanction was given to the plan by Parliment in the improvement act of 1866. A much broader scheme than that originally conceived has been carried out under the sanction of later acts with financial results which the following statement shows:

"The total cost of property acquired up to the end of the fiscal year 1893 by the Glasgow Improvement Trust has been as follows:

Within compulsory areas	$7,882,780.24
Oatlands	205,775.27
Overnewton	208,904.57
Cost of erection of two model tenements in Drygate and site thereof	16,672.95
Expenditure on formation of streets, squares, sewers, etc	506,251.25
Lands of Kennyhill and cost of forming same into Alexandra Park	194,660.00
Cost of seven lodging houses, sites, and Moncrieff street ground	435,302.08
Cost of Saltmarket and other new model tenements to date	255,067.52
Total	$9,705,413.88
Of this there has been disposed of—	
For prices and feu duties within central areas	$4,428,227.17
For prices and feu duties at Oatlands	230,418.98
For prices and feu duties at Overnewton	243,858.61
	$4,902,567.76
Giving as the net cost of heritable subjects	$4,802,846.12
Value of property still in the hands of the trustees	2,653,760.40
Deficiency	$2,149,085.72
Total assessment received from the ratepayers since 1866	$2,812,188.42
Excess of liabilities over assets May 31, 1893, which will have to be made by assessing	692,573.05
Total cost to ratepayers from first to last	$3,504,761.47

For this ratepayers have obtained:

1. Alexandra Park.

2. Ninety-seven thousand one hundred and sixty-two square yards of ground, applied in the formation of 29 new streets and in the improvement of 25 existing ones, being 32,492 square yards of street surface beyond what was contemplated in the original scheme.

3. The sanitary and social amenities produced by the street, sewer, and other public works, which cost, as above stated, £104,027 15s. 10d. ($506,251.25.)"

Wherever municipal improvements are made the land adjacent thereto advances in value—it is therefore good business policy for the city not only to buy the property required for the improvements but all property surrounding the same so that the people may gain the "unearned increment" instead of private owners.

"Some of the greatest boulevards of Paris have thus been constructed, practically, without cost to the city, because the adjoining land has been so much enhanced in value that the price received when it was sold has been almost sufficient to meet the cost of public works."

THE CHICAGO DRAINAGE CANAL.

THE city of Chicago suffers from a contaminated water supply by reason of the entire city sewage being emptied into the Chicago river and thence to a great extent, carried into Lake Michigan, where it finds its way in a diluted state into the domestic water supply, through the lake intake tunnels. This water is always more or less impregnated with disease germs, developing epidemic typhoid fever. The city has in the past maintained, as it still does, pumping stations, designed to divert the river current from the lake. These pumping stations are located at Bridgeport, where the water is lifted from the river into the Illinois and Michigan canal, where it flows south into the Illinois river.

This gives only partial relief, however, and, the pumping system not being equal to the task imposed, the Chicago Drainage canal was projected and is now in process of construction, whereby a natural waterway will be created with a natural fall, reversing the direction of the current of the Chicago river so as to pass the water of Lake Michigan through this artificial cut across the continental divide intersecting with the Des Plaines river channel to Lockport, where the controlling works will be located, and thence down the natural fall to and through the city of Joliet and over the natural courses of the Illinois, Ohio and Mississippi rivers to the Gulf of Mexico.

The main channel of the Chicago Drainage canal is the most extensive engineering project in America excepting only the Panama and Nicaragua Ship canal, and when fully matured will bring New Orleans in direct water communication with Chicago. The total amount of excavations in in the main channel is 26,077,765 yards glacial and 12,071-658 cubic yards solid rock aggregating 38,149,433 cubic yards. To this must be added material excavated from the river diversion, 1,564,403 cubic yards glacial drift and 258,926 cubic yards solid rock. Total, river diversion 1,823,329. Grand total, main channel and river diversion, 39,972,762 cubic yards.

Estimated cost of work now under contract	$18,990,078.64
Right of way account	2,606,227.92
Total	$21,596,306.56
Estimated cost of completed canal	$28,000,000.00

The control of the Des Plaines river (which is the key to the valley and had a tendency to wander from its course at certain seasons, thereby causing considerable damage) was one of the first problems to be solved before the work could be safely carried forward. This was accomplished by excavating about thirteen miles of new river channel 200 feet wide at the bottom, parallel to the main chanal, and extending from section C to section A, through portions of sections 1 and 2, and from sections 6 to 11. This river diversion channel includes about ninteen miles of levee between the canal and the Des Plaines watershed. It cost nearly $1,000,000.

The drainage canal is devided into twenty-nine sections, each section averaging one mile in length. Nos. 1 to 15 run southwesterly from Willow Springs, while sections A to O, omiting J, extend east to Robey street. The lettered sections are in earth, sections 1 to 6 are in earth and rock (glacial drift), while sections 7 to 15 are all rock.

The bottom of sections A to E, with 500 feet of section F, is 202 feet wide. East of these the width is 110 feet. Sections 1 to 15, except a portion at the south end of the latter, are 160 feet wide at the bottom. The width at the top of the earth sections is 306 feet.

The fall in earth and glacial drift from Robey street to Willow Springs is about one and one-half inches to the mile; in solid rock (Willow Springs to Lockport) the fall is about three inches to a mile. The bottom of the channel at the controlling works will be about 5¾ feet lower than at Robey street.

The sides of the rock sections are vertical; those of the earth sections slop away towards the top. The walls of the sections in glacial drift (Nos. 1 to 6) are masonry laid in cement.

The average depth of the canal is from 30 to 36 feet and the average depth of water will be from 22 to 24 feet. The canal's greatest depth is 46 feet.

A flow of 300,000 cubic feet of water a minute, sufficient to take care of the requirements of the city's present population, will be permitted by the canal's present dimensions. Later, when the growth of the city demands it, the earth sections may be dredged to permit the passage of 600,000 cubic feet, or 4,500,000 gallons per minute. This will be ample for 3,000,000, people which "Greater Chicago" confidently expects to have. Numerous springs were tapped during the excavations, and their waters cover the floors of sections that are finished. The contractors must keep their sections free from water until the canal is accepted by the State board of commissioners to be appointed by the legislature.

It is reasonable to anticipate the completion of the canal, including the works at Lockport to regulate the flow of the water into the Des Plaines.—*Cement and Engineering News.*

THE "PETRIFIED CITY."

AMONG cities of fable the petrified variety was interesting. We have it in most parts of the world—our prosaic islands knew it, but as a submarine curiosity. In the days when London enjoyed the presence of an Ambassador from Tripoli, that personage astonished the Royal Society once at least. The famous traveler, Dr. Shaw, had mentioned the story of a petrified village near Cyrene. Scientific people derided it, scientific people upheld it—in short, a discussion arose. Some members of the Royal Society, recollecting that there were grave and responsible inhabitants of Tripoli within reach, put the question before the Ambassador. He explained with a vengeance. One of his friends, a person of course, whose honor could not be impugned, was well acquainted with the spot. Shaw made a great mistake in describing it as a village. City was a proper word. The walls enclosed an exact circle, numerous streets crossed at right angles, with shops and avenues of trees, and a noble castle stood in the midst. In the shops and streets were people variously employed—the gentlemen noted, in especial, a baker and his customers' loves in hand, a woman suckling her baby, and so forth. He entered the castle and found a king, or somebody of rank, lying on a gorgeous bed with guards about him. Animals abounded, such as donkeys, camels, oxen, sheep and birds. But everything was stone of a peculiar bluish tint, even the money lying on the shop counters and in people's hands; witness brought a quantity away, and the Ambassador regretted that he could not find some pieces presented to himself at the moment. A description was forthcoming, however; the coins were as large as English shillings, with a horse's head on one side and writing in unknown characters on the other. A happy little touch represented that many of the figures had lost head or limbs—petrification will not endure forever, of course. The Royal Society expressed warm gratitude for this communication. It is scarcely worth while to seek the origin of a fable which is sufficiently explained by the vagaries of imagination. That it was localized at Cyrene—among countless other spots—may be due to the existence of a large and well-preserved necropolis there, with many statues erect in Shaw's time, if not now. He himself made a long and perilous journey to Harnam, in Numidia, where, as the Arabs avouched, a Bedouin encampment was on view, surrounded by oxen and sheep, all turned to stone. In this instance no shadow of foundation for the legend could be found. But it was so widely diffused in those days that rumors of the marvel reached the court of France, and M. le Maire, Consul at Tripoli, received instructions to inquire. He employed some Janissaries, who even undertook to bring away a petrified Bedouin; but they pointed out, very reasonably, that a full-grown specimen would be too heavy. The Consul declared that a baby would satisfy him, to begin with at any rate. After many months, during which his interest was kept up by frequent drafts for expenses, the Janissaries returned, and sure enough they had a stone baby—a very pretty one too, for it proved afterwards to be a little statue of Cupid found among the ruing of Leptis; they had broken off the wings and quiver. Bruce also was tempted to visit this spot, called Ras Sem; and Captain Smyth, of her Majesty's ship "Adventure," went in search of it, bnt in another direction. The Sultan of Fezzan told him a story much like the Ambassador's, and he traveled, full of hope, nine days through a desert country. In this case, however, there were really buildings and bas-reliefs of men and animals, if not statues.—*London Standard.*

PERMATURE OCCUPATION OF NEW HOUSES: A TEST FOR RELATIVE HUMIDITY OF HABITABLE APARTMENTS.

REGARDING newly built houses, sanitarians, for the most part, teach us that a period of four months in summer and six in winter ought to be allowed between the end of the building operations and the entrance of the inhabitants into a house. In this way will be avoided the accidents that arise from the premature occupation of an apartment. It is scarcely necessary to add that, as soon as the house has begun to be occupied, to avoid dampness it should be heated and ventilated; treated, in a word, by all the usual means to maintain a healthy condition of the apartment. If the dampness persists in spite of all these precautions, the proprietor is responsible for the defects in his building. Physicians are sometimes requested to estimate the relative dampness of an apartment or room. This is not always easy by simple inspection, as a room may be damp although saltpetre does not grow on its walls or mould in its corners. The following is an exact means of appreciation, and one that is within every one's scope: In the room in question a kilogramme of fresh lime should be placed, after hermetically closing doors and windows. In twenty-four hours it should be weighed, and if the lime has absorbed more than ten grains of water (that is, more than one per cent) the room

should be considered damp and classed as unhealthy. The question of dampness of dwellings is a frequent cause of dispute between landlord and tenant, naturally solved in the affirmative by the latter and in the negative by the former. The question can be settled in the future by the test of the hydration of lime of which I have just spoken, and which will give irrefutable proof or refutation of the validity of such complaint. The dampness of dwellings is a cause of illness. The death rate is greater in quarters where the apartments are damp than where they are dry. Ventilation is defective where the walls are impregnated with water; the porosity of the walls is done away with, and can only be re-established after the evaporation of the water has been completed, and the heat required to effect this evaporation is furnished by the person living in the room. This is the cause of the vivid impression of cold which we experience in damp places, and it is a well-known fact that exposure to the action of the cold renders the organism more accessible to the attack of morbid germs. The rotting of walls, which appears particularly in places where the water used in building contained nitrates and chlorides, is caused by changes from dryness to dampness and *vice versa*. It gives rise to fragmentation of the mortar, and even of the building stones themselves. Finally, frost can split a wall that is soaked in moisture. The dampness of dwellings is due to internal or external causes. There can be no doubt that a new building ought to be treated for a certain length of time by ventilation and heat, with a view to evaporating the enormous amount of water incorporated with the building materials. According to Pettenkofer, a three-story house requiring 167,000 bricks would need some 835,000 litres of water to build. When this evaporation has been effected great care should be taken in insuring proper drainage for rain and other water.—*Journal American Medical Association.*

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street.

Seth Babson, Pres. W. P. Moore, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Octavius Morgan, Pres. A. M. Edelman, Vice-Pres.
Arthur B. Benton, Sec't. August Wackerbarth, Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

Geo. W. Dickie, Pres. W. G. Curtis, Vice-Pres.
Otto Von Geldern, Sec. Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

Oscar Lewis, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. M. V. Brady, Sec.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

STORES and Flats for the Phelan Estate corner of South Park and Third street, William Curlett, architect.

NOTES AND COMMENTS

Mr. Chas. S. Tilton, the present City and County Surveyor has been renominated for that office. He is well-known among architects as a man who can be relied upon for good work in his profession.

THE Sixth Annual Banquet of the Builders' Exchange was held October 24, 1896, at 40 New Montgomery street, visiting builders from Oakland and San Jose, invited architects and members of the press were in attendance. It was an unusually enjoyable affair; songs and speeches that were received with applause were the order of the evening and we regret that our space will not allow us to reproduce some for these admirable addresses.

Mr. Laver the veteran and well known architect, member of the firm of Laver & Mullany has just returned from a trip east and to Europe.

Articles of incorporation have been filed by the Fraser Electric Elevator Company. The directors are Ethelbert M. Fraser, George Crocker, Charles E. Green, John J. Mahoney and A. J. McNicoll. The capital stock has been placed at $100,000 and of that sum $500 has been subscribed.

BOOKS AND PERIODICALS

THE STONE INDUSTRY IN 1895, by William C. Day. Extract from 17th Annual Report of the Geological Survey of 1895–6. Department of the Interior. Contains a very valuable survey of the Stone Industry for the Year 1895.

We republish the following table for the benefit of our readers of the Pacific Coast.

VALUE OF DIFFERENT KINDS OF STONE PRODUCED IN THE UNITED STATES DURING THE YEAR 1894 AND 1895.

KIND	1894	1895
Granite	$10,029,156	$ 8,894,328
Marble	3,199,585	2,825,719
Slate	2,790,324	2,698,700
Sandstone	3,945,847	4,111,314
Limestone	16,190,118	15,308,755
Bluestone	*a*900,000	*a*750,000
Total	$37,055,030	$34,688,816

a Estimated.

Of the total valuation of $34,688,816, Pensylvannia takes about five and one-half millions, Vermont and Ohio come next with about three million a piece, while California is about in the middle of the list of states with $700,000.

As to the several kinds of stone, of granite, Massachusetts supplies the largest amount with nearly two million dollars worth, then comes Maine with $1,400,000 and California below the middle of the list with $348,806.

The value of marble product by states is shown in the following table:

VALUE OF MARBLE PRODUCT FOR THE YEAR 1895, BY STATES

STATE	VALUE	STATE	VALUE
California	$ 22,000	New York	$ 207,828
Georgia	689,229	Pennsylvania	59,787
Idaho	2,250	Tennessee	362,277
Iowa	13,750	Vermont	1,321,598
Maryland	145,000		
Massachusetts	2,000	Total	$2,825,719

The following table shows the output of roofing and milled slate in 1895:

VALUE OF SLATE PRODUCT IN 1895, BY STATES.

State	Roofing slate Squares	Value	Other purposes (value)	Total value
California	1,500	$ 10,500	.....	$ 10,500
Georgia	2,500	10,675	.....	10,675
Maine	23,774	118,791	$ 21,363	40,154
Maryland	13,188	59,157	1,200	60,357
New Jersey	200	700	.....	700
New York	13,624	90,150	1,725	91,875
Pennsylvania	426,687	1,437,697	210,054	1,647,751
Vermont	221,359	531,482	93,849	625,331
Virginia	27,095	92,357	19,000	111,357
Total	729,927	$2,351,509	$347,191	$2,698,700

Of Sandstone produced Ohio takes the lead with one million and a half dollars worth—the next is Pensylvania with only one-half million—Ohio produces nearly as much as all the other States put together—California pro duced to the amount of twelve thousand while Arizona produced twenty thousand dollars.

The remarks of the author on the State of the several stone industries in the States of the Pacific Slope are as followers:

GRANITE

"CALIFORNIA—In 1894 the granite output was valued at $307,000; in 1895, at $348,806. The gain of $40,000 is quire noteworthy, in view of the fact that in some other industries the year did not come up to 1894 in prosperity. Some of the producers speak encouragingly of the prospects for 1896. The paving-block industry is at present suffering from the increasing use of the bituminous rocks mined in the State; furthermore, overproduction of blocks in 1893 and 1894 told decidedly on the output of 1895, and, as a further consequence of carrying old stock, prices were reduced. Collections are still slow, and frequently three or four months' time had to be given in order to make sales.

"COLORADO—The output of granite fell off somewhat in 1895, owing to the shutting down of a number of quarries, leaving but few active producers. These, however, speak somewhat encouragingly of the prospects for 1896.

MARBLE

"CALIFORNIA—Marble quarrying in California was very much restricted during 1895, and producers, without exception, have expressed themselves in the most unqualified manner to the effect that there was scarcely any inducement to continue quarrying during the year. Operators are awaiting such revival in business as will justify them in renewing their efforts. Under ordinarily good conditions of trade the State is equal to a production of marble valued at $100,000 per annum, but, as is evident from the table of production, the figure for 1895 is far below this limit.

"IDAHO—A small amount of marble was produced in Cassia County during 1895. Large amounts would doubtless be quarried if business were in a normal condition. Quarries are at present being opened near Albion, Cassia County, and an output may be looked for from these in 1896."

In regard to marble the greatest advance has been in Tennessee marble as shown by the table. Much is imported into California although we have just as pretty marbles here waiting for cheap freights.

SLATE

"CALIFORNIA—While the production of slate in California has never yet reached large proportions, the product has always commanded a good price. The demand for slate as a roofing material is curtailed by the cheapness and excellence of redwood shingles produced in the State. There is no reason at present to expect that the production of roofing slate will increase markedly within the next few years. The output comes entirely from Eldorado County."

SANDSTONE

"ARIZONA—Quarries near Flagstaff were in operation during the year, producing an output valued at $20,000.

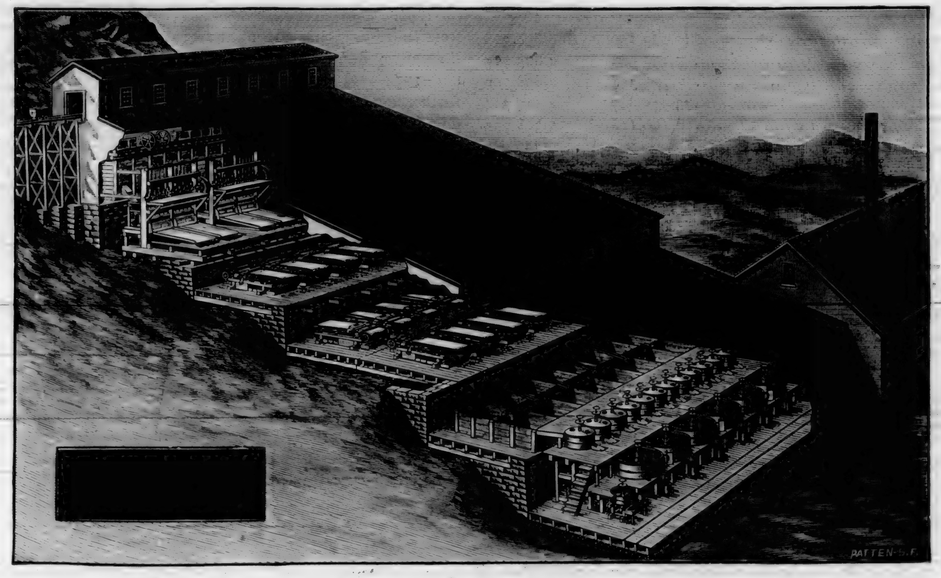
This speaks well for the development of what may be before long an industry of some magnitude.

"CALIFORNIA—Reports of operations in sandstone quarrying in California are rather discouraging, and an output valued at $11,933 is much smaller than was produced in this State a few years since. Building operations were very much curtailed in the past year.

"COLORADO—When the large sandstone outputs of 1890 and 1891 are considered, it is evident that at present the possibilities in this industry are far from being realized. It is encouraging to note, however, that better conditions for 1896 are unhesitatingly predicted by a number of the producers."

LIMESTONE

"ARIZONA—It is only within the last few years that lime-



COMBINATION MILL SHOWING DOUBLE CONCENTRATION WITH FRUE VANNERS.

stone production has amounted to anything more than a very small figure. Since 1893, however, there has been a regular annual increase. In 1895 the product was valued at $24,159. More than one-half of this figure is the value of lime made.

"CALIFORNIA—The value of the product in 1895 was $322,213; this figure includes the value of lime made, namely, $244,580. The remainder was used mainly for rough building and roadmaking. Dull trade is complained of, and a number of the smaller operators ceased quarrying for the year.

"COLORADO—Most of the output of limestone in Colorado is used for fluxing and smelting gold and silver ores. The total value of the output was $116,355 of which $83,346 worth was for limestone used as flux. The output is a little behind that of 1894."

The moral to be derived from these remarks is that California is only waiting for better times to have its enormous resources developed.

EXAMPLES OF METAL WORK published by The J. L. Mott Iron Works, New York, is got up in the style of an *Editor de Luxe*, and consists of illustrations showing recent examples of the work which are representative in character rather than specially costly or extravagant in design. As they are addressed to professional men no long description of the nature and construction of the various subjects are given which may be considered in accord with the graphical spirit of the age.

They are all from actually executed works which work is claimed to have been done in a manner faithfully carrying out and carefully reproducing the intentions and wishes of the several architects whose designs are here exhibited, and exhibit a certain propriety in the choice and treatment of the different metals and some regard to the architectural character of the surroundings.

The examples include grills, elevator enclosures, elevator cars, entrance doors of bronze, office fittings, cafe screen, entrance gates and fences, staircase railing, wall crestings, area railings, window guards, balcony rails, newel and entrance lamps and ecclesiastical and funeral metal work in bronze, polished brass, electro bronze, forged iron, iron, etc.

From a study of these works one gathers that The J. L. Mott Iron Work is doing just as good work and gaining just as good a reputation in ornamental metal work as they have in their sanitary ware.

THE ARCHITECTS AND BUILDERS REVIEW—A monthly journal devoted to architectural and engineering construction and allied subjects; published by the Burnett Publishing Company, 5 to 11 Broadway street, New York. This new venture in the way of an architectural publication certainly makes a very handsome appearance with new type and good paper; the claim of the editor of his intention to

show a continuous improvement in subsequent issues of the review which will render the journal more and more deserving of the success in its distinctive field of operation which will doubtless be attained; a promise that we hope may be fulfilled. Success to the new venture.

CALIFORNIA, HER INDUSTRIES, ATTRACTIONS AND BUILDERS, Illustrated. J. C. Hoag, publisher, San Francisco. The September number of the above named journal comes to hand with the usual number of half-tone illustrations, that make advertising a pleasure as well as a work of art.

CALIFORNIA STATE MINING BUREAU. J. J. Crawford, State Mineralogist—Bulletin No. 9 contained in a phamphlet of over 200 pages is devoted to the subject of Mine Drainage, Pumps, etc., by Hans C. Behr, Mechanical Engineer. Published at Sacramento, A. J. Johnston, Superintendent State Printing.

The author states "Insomuch as there has not been any comprehensive treatise on this subject within the reach of the majority of the miners of this state, it is expected the present one will prove to be of interest and value." As this pamphlet is fully illustrated with engravings of pumps, with other machinery in use in drainage it cannot fail to be of great use and interest to the miners as well as engineers in general.

STONE—An illustrated magazine issued monthly, published at Chicago. The October number of this valuable journal comes to hand, full of good things of interest to the architect and builder. It is devoted to the interest of stone and does not congne itself to any section of the country, but illustrates various quarries from all section, North, South, East and West. This journal should be in the hands of every progressive architect in the United States.

DURABILITY OF TIMBER.

A STRIKING instance of the durability of timber, under certain conditions, was afforded during the excavation for the foundation of the Bowling Green Building. A line of spruce piles was discovered at some distance below the surface of the ground which, as far as we can learn, were placed in position about 150 years ago and actually formed a bulkhead, the tide then reaching this point. These piles, upon examination, were found to be perfectly sound, and to all appearances would have been just as sound and good 150 years hence.—*Architects and Builders Review.*

A PLAUSIBLE THEORY.

A VERY plausible theory to account for some of the peculiar trade conditions now existing was advanced by a gentlemen in conversation with a trade press representative recently. While admitting that the talk about changing our financial standard has a great deal to do with the matter, he maintained that we are undergoing a revolution in other directions, and the Western and Southern farmers, and many other people in the industrial centers who blame the financial laws for their present ills, are largely wrong in thus diagnosing the case. Although too many people have an idea that their ailments may be eliminated through legal enactments. The tariff legislation has given this impression to many of the farmers, and they must be educated to see things as they are before correct conditions will prevail. "I may be wrong in my reckoning," he said, "but let me tell you what I think affects the Western farmers more than the conditions of the national finances. In cities like Boston, Brooklyn, and scores of others of lesser population in this country, while trolley cars are now the rule, thousands upon thousands of horses have been relegated out of date. In the city of Chicago alone between two and three hundred thousand persons ride bicycles. Probably New York, Philadelphia. Boston, Washington, St. Louis, San Francisco, Baltimore, and other communities of large population show a similar precentage of bicycle riders. Just figure out how the casting away the horses by the trolley cars and the general riding of bicycles affects the Western farmers in horse and oat production. Why, if the figures were at hand they would be something tremendous, and it is my opinion that in this one direction the farming interests of the country have been more affected than they have by any of the ills which the politicians say are due to our financial conditions. These ills are largely imaginary, but it is a fact that the horse has been largely superseded by the trolley and the bicycle, and the farmers, who represent three-fifths of the population of the United States, are the great sufferers, and indirectly, of course, the wage earners in the industrial centers suffer."—*Geyer's Stationer.*

WONDERFUL THINGS THAT ARE NEAR.

Flying is solved. The principle is known. A mechanical expedient is all that is now needed to make it successful. Practical flight is to-day not more than five or ten years off.

The glowworm makes light with about one three-hundredth part of the force used in ordinary artificial light. When men know how to make light as cheap, streets and homes will be as light as day for a mere fraction of what light now costs. This is near. Vacuum illumination without incandescence is already in full operation, and in a year or two should cut down the price of light to a sixth of its current cost, and in five or ten years light in a city may be, like water, turned on in every home at will.

Compressed air has long been known to be the best way, theoretically, to store force for use in transportation. There is no waste and no deterioration. The need is a cheap and efficient motor to apply compressed air to the city transportation. If this can be done, first the trolly poles and wires will come down, next the horseless, air-compressed motor carriages will do all the work of the city delivery.

When these changes come the only use for gas will be for cooking—if this is not done by electricity. Factories, also, before many years, will be run by transmitted electric power. This has begun to be done, and in five or ten years will be completed, and the factory fire and boiler will be a thing of the past.

The city of the future, and no very distant future, will have no trolly poles or wires and no horses. All movements will be on rails by silent air motors or by horseless

carriages equally silent. All pavements will be asphalt. Unlimited light will be as cheap as unlimited water is today. No coal will be delivered at private houses and no ashes taken from them. With no horse, no coal, and no ashes, street dust and dirt will be reduced to a minimum. With no factory fires and no kitchen or furnace fires, the air wall be as pure in the city as in the country. Trees will have a chance. Houses will be warmed and lighted as easily and cheaply as they are now supplied with water.

A city will be a pretty nice place to live in when the first twenty years of the twentieth century are passed.—*Philadelphia Press.*

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

COMPLETION OF ARCHITECT'S CONTRACT AND TIME FOR FILING LIEN.—A building contract provided that all payments to the contractor should be made on certified statements of the architects, who were empowered to supervise the construction of the building at a compensation of five per cent of its cost, and that final settlement should be made on their certificate, showing completion of the contract according to specifications. The Supreme Court of Wisconsin held that, as the last act required of the architects was to give a final certificate of satisfactory construction, their time for filing a lien for services did not begin to run until the performance of such act.

Bentley v. Adams, 66 N. W. Reporter, 505.

HOMESTEAD NOT EXEMPT FROM MECHANICS' LIEN.—A claim of homestead cannot be asserted against a mechanic's or material man's lien.

McNally v. Hawkins Lumber Co., Supreme Ct. Ala., 19 So. Reporter, 417.

LIABILITY FOR PROMISED PAYMENT BY A THIRD PERSON.—One who induces a contractor to perform labor or furnish materials by the promise that a third person, who he claims owes him a debt or duty, shall pay to the contractor the agreed price of the labor or materials he furnishes, becomes primarily liable to pay the contract price himself if he receives the fruits of the contract and his debtor does not pay, or the debt or duty did not in fact exist.

Barber Co. Denver, 72 Fed. Rep. 336.

ABRIDGEMENT OF CASES INTERESTING TO ARCHITECTS AND CONTRACTORS.

WHEN CONTRACTOR IS NOT LIABLE FOR DANGEROUS PREMISES.—The failure of a contractor, having a building on a street under construction, to protect a runway leading from the sidewalk into the building, and intended for the use of his employes alone, does not render him liable for the death of a trespasser, who, merely to satisfy his curiosity by an inspection of the building, went on the runway, from which he fell into the cellar of the building.

McNeven v. Arnott, Sup. Ct. App. Div. 1st Dept. 38 N. Y. S. 759.

RIGHT OF LIEN WHERE LAND BELONGS TO THIRD PARTY.—A person who furnishes materials for use in the erection of buildings on land to one in possession of same, under contract of sale, may acquire a mechanic's lien on the premises for any unpaid amount of the price of the materials; but if there is no agreement between the vendor and vendee of the land that the improvements shall be made, the lien can only attach to the interest of the vendee and will be subsequent and inferior to that of the vendor for any balance of the purchase money remaining unpaid.

Fuller v. Pauley, Sut. Ct. Nebr., 66 N. W. Reporter, 1115.

BUSINESS MOSAICS.

Messrs. N. & G. Taylor Co., Philadelphia, manufacturers of tinplates, report a large and steadily growing business in their roofing tin in rolls. These rolls are sheets of tin soldered together with the aid of rosin, no acid being used. They are then thoroughly painted on one side, and carefully put up in rolls ready for shipping.

These rolls are particularly adapted for quick contracts as the tin is all ready for instant use, and for laying on the roof. Messrs. N. & G. Taylor Co. originated the idea of continuous roofing tin some thirty (30) years ago, and do the largest business in this line of any house in the country. They make the tin in all grades from their celebrated "Taylor Old Style" brand, extra heavy coated, down to ordinary grades.

They are also agents for "The Pancoast Ventilator," which is recoguized among the technical as being made under scientific principles, and to be a ventilator that ventilates. They invite correspondence.

"After all, I don't think she is so awfully homely." She has one of those faces that grow on you." "I'm glad it didn't grow on me."

Hargreaves—I had an uncle who knew a week before the exact day and hour he was to die. FERRY—Who told him, the sheriff?—*Cincinnati Enquirer.*

We should judge that the business of Keatinge, Leonard & Ransome must be good, by the loads of twisted iron and barrels of cement we see piled near buildings now under construction, their office is at 11 and 12 Nucleus Building, San Francisco, Cal.

Ethel—Mamma, what makes the lady dress all in black? MAMMA—Because she's a Sister of Charity, dear. ETHEL—Is Charity dead, then?—*Princeton Tiger.*

If you want Tacoma and Roche Harbor Lime, address the company, box 289 Builders' Exchange, 40 New Montgomery street, San Francisco. The claim is made that this is the purest lime in the world—it has been awarded the first prize at the World's Fair, and also at various other fairs.

"But why do you not print a card and deny the accusation?" inquired the politician's wife. "Deny it?" howled the politician, "and then have them prove it? No; I will treat it with contempt.—*Truth.*

W. R. Grace & Co, 203 California street have Portland cements of various brands. It is evidently the intention of dealers in this article, that this city shall be stongly cemented.

Hospital PHYSICIAN—You are bruised too, I see." PATIENT—Yes, I came in an ambulance.—*Dispatch.*

Gladding, McBean & Co., manufacturer of architectural terra cotta, pressed brick, drain tiles, etc., are at the old address, 1358–1360 Market street, San Francisco. This firm and its products are so well and favorably known to the building public that their present address is all that is required to be given.

Edward B. Hindes & Co. 411 Mission street, San Francisco, Manufacturers of Hall's Patent Inside Sliding Blinds, Perfection Window Screens, latest improved venitian blinds and rolling wood partitions. Catalogues and prices sent on application to the above address.

The John Douglass Co., manufacturers of an absolutely noiseless tank, invite the public to visit their show room, 208 Ellis street, San Francisco, and inspect the superior quality of seats and crockery. The cut in their add page VIII speaks for itself.

To those who are preparing for the storms and wish a new coat of paint upon their houses, we would say they can obtain "facts about paint" as well as paint that is a fact, without adulteration from that well known firm of W. P. Fuller & Company.

"She gets her complexion from her mother's folks." "Ah, indeed. Are they druggists, then?—*Detroit Tribune.*

The Norton Door Check and Spring, makes slamming doors impossible, an air cushion check which is changed by opening the door; go and see it at 593 Mission street, Mr. Frank D. Morrell will tell you all about its merit.

Small Boy—Say Pop, why do they have harps in Heaven? STERN PARENT—Becauses the Lord loveth a cheerful lyre, I suppose.

We would call the attention of our readers to a notice in another part of this journal to the handsomely illustrated catalogue of The J. L. Mott Iron Works. M. S. James, in the Flood Building, is the agent on the Pacific Coast and can show the articles so well illustrated.

CITY BUILDING NEWS.

Alabama nr 24th. Additions and alterations; owner, Margeret M. Kehoe; architect, M. J. Welsh; contractors, T. R. Bassett & Bro; signed, Sept. 14; filed, Sept. 15; cost $1500.

Baker near Washington. To build; owner, Mrs. Julia L. Maris; contractor, T. T. Pottinger; signed, Sept. 10; filed, Sept. 11; cost $4000.

Baker near McAllister. To build; owner, Bertha Klaber; contractor, John J. Boyle; signed, Sept. 14; filed, Sept. 16; cost $3200.

Brannan near Fourth. Marble work for alter; owner, Rev. D. Nugent; architect, B. J. Clinch; contractors, Pierce & Carter; cost $945.

Brannan near Fourth. Interior marble work; owner, Rev. D. Nugent; architect, B. J. Clinch; contractors, Pierce & Carter; signed, Aug. 18; filed, Oct. 6; cost $1610.

Brannan near Fourth. Stain glass windows; owner, Rev. D. Nugent; architect, B. J. Clinch; contractor, T. C. Butterworth; signed, Oct. 6; filed, Oct. 6; cost $1500.

Broderick near Post. Cottage; owner, M. Solomon; architect, Emil John; contractors, Lorenzen & Fevrie; signed, Oct. 6; filed, Oct. 7; cost $2800.

Broderick near Bush. To build; owner, Rachel H. Lambert; plans by G. Lambert; contractor, Hugh Keenan; signed, Sept. 14; filed, Sept. 14; cost $3500.

Brighton Ave. near Grand Ocean Boulevard; owner, Sadie Robertson; architect, B. A. Brown; contractor, Chas. Alsup; signed, Sept. 15; filed, Sept. 23; cost $2250.

Buena Vista near Sacramento. To build; owner, L. Coutard; architect, J Godart; contractor, F. F. Sarcander; filed, Sept. 19; cost $2758.

California and Leidesdorff. Skylights; owner, Merchant's Exchange; architects, J. J. and T. D. Newsom; contractors, Moore & Cameron; signed, Sept. 3; filed, Sept. 8; cost $1118.

California Ave., lot 129. To build; owner, John Devine; architect, J. B. Lo Romer; contractor, J. P. Burke; signed, Sept. 11; filed, Sept. 11; cost $2224.

Clay and Van Ness Ave. Steam heating plant; owner, Claus Spreckels; architects, Reid Bros.; contractors, Geo. Tay & Co.; signed, Sept. 24; filed, Sept. 25; cost $1875.

Clay and Steiner. To build; owner, Clara Kluge; architects, Laferme & Collischown; contractor, T. H. Soule; signed, Oct. 1; filed, Oct. 3; cost $6987.

Clay and Steiner. Plumbing; owner, Clara Kluge; architects, Laferme & Collischown; contractors, Shepard Bros.; signed, Oct 1; filed, Oct. 3; cost $750.

Clay and Steiner. Painting, tinting, etc.; owner, Clara Kluge; architects, Laferme & Collischown; contractor, Sartorio & Co.; signed, Oct. 1; filed, Oct. 6; cost $600.

Church near 15th. Alterations and moving; owner, Fannie Beguelin; architect, Havens & Toepke; contractor, John McKay; signed, Sept. 15; filed, Sept. 19; cost $2550.

Crescent Ave. near Mission. Cottage; owner, J. Heyman; builder, J. Heyman; cost $1000.

Davis and Sacramento. Addition and repairs; owners, Sol. Wargenheim & Co.; architect, James E. Wolfe, day's work; cost $1200.

Devisadero near Waller. To build; owner, Louis Muller; architect, H. Geilfuss; contractor, A. G. Johnson; signed, Sept. 28; filed, Sept. 28 cost $2000.

Eighth Ave. near Point Lobos. To build; owner, Rev. John P. Doyle; architects, Shea & Shea; contractor, P. Maloney; signed, Sept. 19; filed, Sept. 25; cost $4575.

Fell near Ashbury. To build; owner, Adolph Weber; architects, Martens & Coffey; contractor, Val. Franz; filed, Sept. 11; cost $4830.

Fell near Ashbury. Sewers, plumbing, etc.; owner, Adolph Weber; architects, Martens & Coffey; contractor, G. C. Sweeney; cost $1000.

Forty-third Ave. near Clement. Cottage; owner, Mrs. A. M. Kruse; contractor, T. L. Williams; signed, Sept. 16; filed, Sept. 19; cost $1650.

Folsom near 24th. To build except mantels, etc.; owner, G. B. Ratto; contractors, Cuneo & Cavaglia; signed, Sept. 21; filed, Sept. 22; cost $4390.

Geary and Stockton. Steel construction for six-story brick; owner, Spring Valley Water Works; architect, Clinton Day; contractor, Pacific Rolling Mill Co.; signed, Sept. 15; filed, 15; cost $61.50 per ten of 2000 lbs.

Grove near Baker. Two-story frame; owner, John Zoller and Catherine Zoller; contractor, Henry P. Conrady; signed, Sept. 12; filed, Sept. 14; cost $3625.

Grove near Baker. To build; owner, T. R. Edwards; contractor, Edward Cox; cost $4200.

Greenwich near Leavenworth. Alterations; owner, Board of Education; architect, C. J. Havens; contractor, W. Linden; signed, Sept. 17; filed, Sept. 19; cost $1078.

Greenwich and Jansen Ally. To build; owners, A. Schabiague and T. Schabiague; architect, J. Godart; contractor, P. A. Antonelli; signed, Sept. 17; filed, Sept. 19; cost $2960.

Grant Ave. and Sutter. Alterations and additions; owner, Mrs. Alice P. Sullivan; architect, E. R. Swain; contractor, Mahoney Bros.; signed, Sept. 21; filed, Oct. 1; cost $18,550.

Grant Ave. and Sutter. Plumbing, etc.; owner, Mrs. Alice P. Sullivan; architect, E. R. Swain; contractor, W. F. Wilson; signed, Sept. 22; filed, Oct. 1; cost $3577.

Guerrero near 27th. Alterations and additions; owners, Catherine Carr and Hattie J. C. Bain; contractor, A. Klahn; signed, Sept. 17; filed, Sept. 24; cost $1182.

Pierce near Filbert. Cottage; owner, C and A. Kober; contractor, C. Douglass; signed, Sept. 28; filed, Oct. 1; cost $1345.

Haight near Laguna. Copper roof; owner, San Francisco Protestant Orphan Asylum; contractor, Pacific Sheet Metal Works; signed, Sept. 12; filed, Sept. 14; cost $3223.

Harper near 30th. Cottage except mantels, etc.; owner, Constance Chaix; architect, E. Deplerre; contractor, Becass & Dupasse; signed, Sept. 15; filed, Sept. 15; cost $1540.

Hollis and O'Farrell. Plumbing, etc.; owners, Emil and Felicien Bareilles; architect, J. Godart; contractor, E. Hogan; signed, Sept. 21; filed, Sept. 26; cost $1450.

Jackson near Steiner. To build; owner, Alfred Bouvier; architects, Mathisen & Howard; contractors, Allyn & Doard; signed, Sept. 25; filed, Sept. 28; cost $4084.

Jackson near Walnut. To build; owner, Charles T. Barker; architect, C. M. Rousseau; contractor, Val Franz; signed, Sept. 28; filed, Sept. 24; cost $4250.

Kearny and Filbert. Planking school yard; owner, Board of Education architect, C. J. Havens; contractors, Holm & Sheibley; signed, Sept. 18; filed, Sept. 21; cost $796.

Lake View Tract, block 24. Two dwellings; owner, Fannie Caley; contractor, J. A. Eastman; signed, Sept. 21; filed, Sept. 30; cost $3000.

Larkin near Greenwitch. To build; owner, Annie McBride; contractor, T. F. Mitchell; signed, Sept. 21; filed, Sept. 21; cost $2000.

Lott near Golden Gate Ave. Additions and alterations; owner, Thomas Kane; contractor, S. H. Farrell; signed, Sept. 14; filed, Sept, 18; cost $1400.

Lindley near Castro. Cottage; owner and builder, J. Hegman; cost $1000.

Market and Powell. Marble work; owner, E. J. Baldwin; architect, M. J. Lyon; contractors, Ruffino & Bianchi; signed, Sept. 2; filed, Sept. 21; cost $1033.

Market near 5th. Fixtures, etc.; owner, Mrs. A. M. Parrott; architects, Pissis & Moore; contractor, R. Herring; signed, Sept. 30; filed, Oct. 2; cost $2875.

Market near Steuart. Store fixtures; owner, Smith's Cash Store; architects, Shea & Shea; contractor, Home Mnfg. Co.; signed, Oct. 7; filed, Oct. 7; cost $4700.

New City Hall. Marble tiling; owners, City of San Francisco; architect, Frank T. Shea; contractor, W. H. McCormick; cost $5340. Marble wainscoting; contractor, Ingo Marble Co.; cost $4798. New Roof; contractor, James J. O'Brien; cost $129,788. Cement; contractor, Spreckels & Co.; cost $6450.

Noe near 13th. To build; owner, Estella H. Williams; contractor, W. W. Rednell; signed, Oct. 3; filed, Oct. 3; cost $2200.

Ocean House Road at Ingleside. Carriage sheds, etc.; owner, Pacific Jockey Club; architect, T. J. Welsh; contractor, Alexander Campbell; signed, Sept. 23; filed, Sept. 24; cost $1833.

O'Farrell near Hollis. To build; owner, Rubin T. Hopkins; architects, Townsend & Wyneken; contractor, G. M. Salsbury; signed, Sept. 15; filed, Sept. 15; cost $1640.

Page and Webster. Carpenter work; owner, Westminster Presbyterian Society; architect, Chas. Geddes; contractors, Campbell & Pettis; signed, Sept. 12; filed, Sept. 12; cost $9800.

Parnassus Ave. bet. 2d and 4th Ave. Granite and brick building for three affiliated colleges; owner, State of California; architects, Kraft, Martens & Coffey. Granite work; contractors, Rae Building Co.; $143,500; grading sublet to A. E. Buckman. Carpenter work; contractor, S. Carle; $67,219. Plumbing; contractor, G. C. Sweeney; $11,193. Galvinized iron work; contractor, J. F. Forderer; $9975. Heating and ventilation contractor, F. J. Lawton; $8325. Iron work; contractor, Pacific Rolling Mills; $4925. Painting; contractor, D. Zelinsky; $3780.

Powell near O'Farrell. Plumbing, etc., for brick building; owner, Geo. D. Toy; architects, Herman & Swain; contractor, H. Williamson; signed, Sept. 12; filed, Sept. 12; cost $2924.

Powell near O'Farrell. Skylights for a market building; owner, Geo. D. Toy; architects, Herman & Swain; contractor, C. J. Guilfoy; cost $100.

Post near Stockton. Metal lathing and plastering for six-story brick; owner, Hobart Estate; architects, Percy & Hamilton; contractor, J. J. Morehouse; signed, Sept. 14; filed, Sept. 14; cost $5375.

Sacramento near Cherry. To build; owner, Patrick Ford and Ellen Ford; architect, C. J. J. Devlin; contractor, T. J. Crawford; signed, Sept. 16; filed, Sept. 18; cost $2890.

Sanchez and Duncan. To build; owner, Frank Straub; contractor, Daniel Einstein; signed, Sept. 28; filed, Oct. 2; cost $2300.

Scott near Bush. To build; owner, Richard O'Connor; architect, Thos. J. Welsh; contractor, W. S. Boswell; signed, Sept. 7; filed, Sept. 12; cost $2591.

Sutter near Kearny. Store fixtures; owner, Sebenbaum & Co.; contractor, Home Manf. Co.; cost $2800.

Sutter and Hyde. Bell work, etc.; owner, Dr. J. Rosenstirn; architects, Salfield & Kohlberg; contractor, J. H. Wolf; signed, Sept. 17; filed, Sept. 25; cost $1600.

Tenth Ave. near Point Lobos. To build; owner, Mrs. Delia Thornton; contractor, T. C. Cochrane; signed, Sept. 14; filed, Sept. 19; cost $1300.

Twelfth Ave. near California. To build; owner, Minnie Armstrong; architect, J. E. Vogel; contractor, F. V. Daniels; signed, Sept. 14; filed, Sept. 16; cost $1500.

Twenty-first near Hamshirs. To build; owner, G. W. Write; contractor, A. Petry; signed, Sept. 25; filed, Sept. 26; cost $1300.

Union and Webster. To build; owner, Albert Landsberg; architect, W. H. Armitage; contractor, Geo. Connon; signed, Sept. 4; filed, Sept. 4; cost $2400.

Wisconsin near Sierra. To build; owner, Robert Scott; contractor, Geo. McLeod; signed, Sept. 25; filed, Sept. 28; cost $1530.

PREMISES OF NEW SAN FRANCISCO POST-OFFICE, AUTHORIZED BY ACT OF CONGRESS, MARCH, 1887.

EXISTING POST-OFFICE BUILDING AT SAN FRANCISCO, CALIFORNIA.

SINCE our last issue, Mr. William Mooser, one of the prominent architects of San Francisco has passed away. He was sixty-two years old, a native of Geneva.

Since his arrival in the country in 1854 he has left many monuments of his skill in architecture along the years. Among his latest works are the New Western Hotel and the New French Hospital. Also the Macdonough Theatre in Oakland, the last while he was associated with Mr. Cuthbertson, the last two take rank with the best of their class any where. Of late years he has been associated with his son William.

His death makes many regrets among those who admired him for his uprightness and honesty and the conscientiousness with which he did all his work. He was a member of the San Francisco Chapter of the American Institute of Architects.

WE LEARN from the *Berkeley Daily Advocate* of the munificent gift from Mrs. Phebe A. Hearst to the California University at Berkeley. Governor James A. Budd, Professor Wm. Carey Jones and Regent J. B. Reinstein are named as the Hearst Trustees.

Four million dollars for buildings from private citizens is something that is not looked for every day—yet Regent Reinstein informed the Board of Regents at a recent meeting that more than four million dollars had been promised by private persons for the construction of buildings according to the plans to be secured through Mrs. Hearst's munificence—if the State would meet the present exigencies and provide indispensible accommodations by simply contributing the interest on five hundred thousand dollars for a term of years.

We publish below the correspondence between Mrs. Hearst, Governor Budd and Regent Reinstein.

PALACE HOTEL, Oct. 22, 1896.

Regent J. B. Reinstein

DEAR SIR:—Referring to the conversation which I had last week with yourself and Professor Wm. Carey Jones, I desire to say that I am deeply impressed with the proposition now before the Board of Regents, to determine upon a comprehensive and permanent plan for the buildings and grounds of the University of California, on the site at Berkeley, and I heartily approve of the idea.

My son and I have desired to give some suitable memorial which shall testify to Mr. Hearst's love for and interests in this State, and after having carefully considered the matter, we feel that the best memorial would be one which would promote the higher education of its people. And I must confess that the absence of a suitable plan for the University buildings has seemed an obstacle in the way of carrying out some ideas which we have cherished.

I feel now so imbued with the importance to the University and to the State of having such a plan that I should be glad to aid in its complete and speedy realization. I may also say that I am the more anxious for this, as I have in contemplation the erection on the University grounds of two buildings, one of them to be the memorial referred to.

I would therefore suggest that I be permitted to contribute the funds necessary to obtain, by international competition, plans for the fitting architectural improvement of the University grounds at Berkeley. While I understand from you that such plans can be procured for about fifteen thousand dollars ($15,000), I desire to say that the success of this enterprise shall not be hampered in any way by a money consideration.

I have only one wish in this matter—that the plans adopted should be worthy the great University whose material home they are to provide for, that they should harmonize with, and even enhance, the beauty of the site whereon this home is to be built, and that they should redound to the glory of the State whose culture and civilization are to be nursed and developed at its University.

As the full execution of these plans will probably require a long period of time, and one of constant and assiduous attention, I should like to suggest that this trust be reposed in a special committee which will represent the several interests involved. I would name as such trustees, His Excellency James H. Budd, representing the State; Professor William Carey Jones, representing the University, and yourself, representing the Board of Regents. I have the less hesitancy in suggesting these names, as these gentlemen are all graduates of the University of California, and would, I am sure, be glad to perform this labor in gratitude to their Alma Mater. Of course the ratification of a final plan would rest with the Board of Regents.

I believe that the release of Mr. Maybeck (who has been identified with the idea of this plan from its inception) from his duties of instruction at the University, and his presence in the Eastern States and in Europe would greatly facilitate a proper understanding of our design among architects. I would therefore further suggest that he be given a leave of absence for one or two years, and I offer to provide for him a reasonable compensation.

Yours very sincerely,

PHEBE A. HEARST.

SAN FRANCISCO, Oct. 23, 1896.

Mrs. Phebe A. Hearst.

DEAR MADAM:—Your letter of yesterday touching an architectural plan for the University of California has been submitted to me, and I beg to say that I shall be happy to accept the trust therein reposed.

Your conception of the purposes of the University of California as a great State institution on the loftiest and broadest plane wherein the State confers the priceless benefits of the higher education, is as noble as it is true.

Such was the great purpose contemplated in the Acts of Congress and of the Legislature of this State founding this University—a purpose whose scope and grandeur has been as thoroughly appreciated by you as your action will spread and enforce its appreciation by others.

Such a plan as you contemplate will enure to the lasting glory and advantage of the State and the State's University, and to the infinite benefit of the people of the State.

In the name of the State of California and on behalf of the people of the State, I tender you their heartiest thanks and assure you of their sincere and lasting gratitude.

Yours very sincerely,

JAMES H. BUDD.

SAN FRANCISCO, Oct. 22, 1896.

Mrs. Phebe A. Hearst.

DEAR MADAM:—I am in receipt of your letter of to-day expressing your earnest wish for an international architectural competition for a permanent and grand plan of the buildings and grounds of the University of California at Berkeley, and also of your splendid gift to further the obtainment of such a plan.

Perhaps nothing at this time could be more opportune or important for the State University than this wise gift and the gracious influence of its donor, through which we may hope soon to obtain a plan which shall contemplate upon the superb site of this University, buildings in every way worthy of a great State and its highest institution of learning. Whatever may be considered the important needs and the factors of success in this University, it is certain that they all will be subserved immeasurably by buildings which shall body forth the power and the dignity of a sovereign State at the same time that they shall exalt education by the inspiration of glorious architecture, making patriotism and a lofty regard for the State as certain a result of a course at this University, as a love for what is beautiful and true.

Your thought and kindness foreshadow such a plan as will accomplish this double purpose, and in addition will spur the pride and interest of State and individuals to speedily realize that plan in useful, beautiful and harmonious structures.

I shall take the earliest opportunity to bring your letter to the attention of the Board of Regents, and with their permission, will accept with pleasure my share of the great trust conferred. In the meantime, permit me to express to you on behalf of all who cherish the welfare of the University of California a sense of deep and lasting obligation. I am, dear madam, Yours very sincerely,

J. B. REINSTEIN.

AIKEN'S DESIGN IS A MONSTROSITY.

WASHINGTON, D. C., Oct. 29.—At last the Supervising Architect has completed his second design for the San Francisco public building. The first design did not please the people of San Francisco. The plans were after the style of Italian renaissance, and were drawn under the immediate supervision of Jeremiah O'Rourke, a talented Irish architect. O'Rourke soon resigned his official position, and was succeeded by William Martin Aiken. Mr. Aiken is nothing if not romantic. It will be remembered that he made a trip to California. He saw the Mission Dolores, visited the Stanford University at Palo Alto and resolved that the halo of romance should surround his design. He determined to give the building a gloomy, dungeon-like effect, with low, deep and dark grated and arched doorways. But not too somber, however, so he stuck two campanile towers on the roof.

The results baffles description. *The Call* correspondent showed a photograph of the design to a number of experts to-day.

"It is an architectural monstrosity," said one of the most famous architects in the United States, the designer of several Government buildings. "There are corner pavilions, but no center pavilion at all. This gives the facade a a severely plain appearance. The centre should have been emphasized by a pavilion. The corner pavilions should hsve been elevated above the balustrano, with the center pavilion towering above all. Yet we might have forgiven all if the architect had not surrounded the structure with two monstrous towers. It was evidently his idea to give the building an Alhambra effect. I do not see much in his design to suggest 'Spanish renaissance,' as he calls it. But if he wished to ornament his roof with turrets he might have better arranged them. The Madison-square Garden, New York, is castallated. There are at least five companile towers, but they are arranged discriminately. Besides, these turrets on a roof garden theatre are well enough. They are lighted brilliantly to advertise the show, but I think turrets are singularly out of place on a Government building. Uncle Sam does not need to advertise his business. The design is not appropriate. Another objection I have is the row of square windows on the mezzanine floor.

"You will observe that the large arched doorways and windows of the ground floor and the windows of the third oor are out of all proportion to the small square mezzanine windows. These small mezzanine windows are only fit for the attic."

This opinion of an expert was concurred in by other architects, who for professional reasons reluctantly criticized the Government architect. Others who saw the picture, although not versed in structural technology, were almost moved to tears when they beheld it. "Heavens," said one, "the architect must have had two turrets in stock he didn't know what to do with, so he stuck them on his Spanish renaissance roof." Another layman suggested that the two high turrets gave a very realistic billy-goat effect. Another wag said by erecting only one turret on one end of these roofs the tout ensemble would be a la locomotive, or with three turrets there would be a devilish pitchfork suggestion.

But Mr. Aiken is apparently well pleased with his design. The following description was given out to accompany the photographs:

"The new Federal building to be built on the square bounded by Mission, Seventh and Stevenson streets is to serve not only as a City Postoffice but also as a United States Rourthouse. The Postoffice occupies the first floor and a portion of the second, while the third floor and part of the second will be devoted to the courts and their dependencies. On the second floor will also be the offices for the United States Pension Agent, while the Weather Bureau will occupy a partial roof story in connection with the towers.

"The building above the first story is in form like an angular letter 'U,' with the base, which forms the main facade, on Seventh street. In the first story and the courtyard, which is roofed, is the Postoffice working room. Corridors run through the center of each division parallel with the three streets and give direct access to each department. The offices of the Postmaster and Assistant Postmaster face Mission street, while on the opposite side of this corridor is the registry division. The Seventh street corridor has upon one side the screen containing the delivery windows, boxes and mailing drops and on the other the stamp of money-order departments and cashier's office.

"The Stevenson street corridor give access to the working room. At the junction of the side and Seventh street corridors are placed the stairs and elevators, in near proximity to the principal entrances, and an information bureau for the benefit of the general public is found at the corner of Mission and Seventh streets, making the plan as a whole most complete and accessible.

"The center of the Seventh street side on the third story is to be occupied by the United States Circuit Court of Appeals, the hightest court of the district, while at Mission street, or the southwest corner, is the Circuit Court, and opposite, at Stevenson street, the District Court. All the courtrooms are provided with the necessary rooms for Judges, juries, clerks and witnesses. The United States Attorney's offices, two law libraries and a large file room for the various documents in charge of the District Court are on this floor, and the United States Marshal has a suite of rooms at the back of the Stevenson street wing, connected directly with the ground by a private staircase.

"On the second floor, under the District Court and easily accessible therefrom, are the rooms of the Grand Jury and Master in Chancery and a number of petty jury rooms. The central part of this floor is devoted to the use of the railway mail service and postoffice inspectors, while the pension office occupies the southwest corner.

"The Circuit Court of Appeals, as befits its importance,

will be the most elaborate room in the building, finished in white enamel embellished with gold, with vaulted ceiling of ornamented plaster. The other courtrooms will be handsomely finished in various hardwoods as well as the connecting offices and libraries, in which latter the bookcases will form a part of the permanent decoration.

The corridors of the first story will have vaulted ceilings finished in mosaic and ornamented plaster, while below the springing of the vaults the walls will be entirely of native marble. The remainder of this story will be finished in hard wood. The exterior of the building which is to be Spanish renaissance in style, will be built of cream white marble, severely plain in the lower stories, except immediately around the entrances, but richly decorated above the third story stringer course and capped by a deeply projecting cornice and balustrade of elaborate design. Crowning all will rise two towers above the intersections of the corridors on the southwest and northwest corners. These towers, while adding must to the appearance of the building, will also serve a useful purpose, as they are intended to accommodate the apparatus and instruments of the local weather bureau."

The Call correspondent asked the supervising architect when work would be commenced on the San Francisco Post-Office building. "Not for several months," said he. "We are now engaged on the foundation plans and there are some engineering problems to be solved. We must determine the weight that can be supported by such a foundation before we proceed."

INTERNATIONAL COMPETITION FOR THEATRE, KIEFF.

MONSIEUR A. Barthelemy has been kind enough to prepare a full and interesting account of the international competition for a theatre at Kieff, and to combine with it particulars which cannot fail to be useful to British architects who may in spite of the short time at their disposal, submit designs for the projected work. Monsieur Barthelemy writes to the *Journal of the Royal Institute of British Architects* as follows:—

The Russian town of Kieff has decided to build a theatre to replace the one which was destroyed by fire. It sends through the Imperial Society of Architects of St. Petersburg an appeal to the architects of all nations; and it is needless to say that the Royal Institute of British Architects is one of the Societies personally appealed to by the Russian body. I cannot do better than give a translation of the regulations for the competition, which will provide our British architects with all the information they require:—

The Imperial Society of Architects of St. Petersburg have received a commission from the Municipal Council of the town of Kieff, to promote an international competition for a theatre to be erected in Kieff.

1. The theatre is to be erected on the site where the former building stood. The main frontage must extend along the Wladimirskaia street, and may be brought nearer to it than formerly. The square may be done away with.

2. The auditorium should accommodate 1,500 persons.

A. Ample space must be provided in the orchestra stalls and pit, with a sufficient number of openings in order to insure a rapid exit for the public. Pit boxes may be erected, but they should not extend all around the auditorium.

B. The boxes, with the exception of boxes to be indicated by letters, must be made to accommodate five persons, in the pit (pit boxes), on the tier, and in front. The galleries must be placed at the back of these. Balconies and amphitheatres may be added.

C. Dressing-rooms, with separate lavatories for ladies and gentlemen, should be set apart on each story.

D. The orchestra should accommodate seventy musicians, with a special lobby, and a room wherein to store the instruments. Separate exits.

3. The boxes should open on lobby-passages. The vestibules should be spacious. Two booking-offices. Cloak-rooms should not be placed in the lobbies. Give special attention to the necessary number and suitable arrangement of staircases. Exterior balconies are allowed.

4. Site for the buffet.

5. The dimensions of the stage should correspond to those of the auditorium, and allow of grand operas being performed, with necessary provision for the prompt shifting of scenery. It is essential that in case of fire the stage could be isolated from the auditorium and the artists' dressing-rooms.

6. Sixteen artists' dressing-rooms for ladies and gentlemen, with special entrances, as well as a lobby and smoking room. Two dressing-rooms for the chorus, each providing accommodation for forty people. A dressing-room for 100 supers. Two dressing-rooms for the ballet, each accommodating ten people. A room for the leader of the orchestra. A room for the stage manager. A room for the leader of the chorus. Three rooms for rehearsals.

7. The manager's room. A room for the impresario. A room for the inspector. A room for the telephone and the heating and lighting apparatus.

8. In a special part or separate should be provided:—

(*a*) Two wardrobes, with a minimum area of 20 square *sagenes*, i. e., 90 square metres.

(*b*) A store-room for the properties, with a minimum area of 10 squares *sagenes* i. e. 45 square metres.

(*c*) A workshop, with a minimum area of 50 square *sagenes*, i. e. 225 square metres.

(*d*) A library, with a minimum area of 9 square *sagenes*, i. e. 40 square metres.

(*e*) A store-room for scenery, providing space for at least thirty operas.

(*f*) A room for painting scenery.

(*g*) Lodgings for the inspector, composed of three rooms and a kitchen, with a total area of 16 square *sagenes*, i. e. 95 square metres.

(*h*) Two rooms for the care takers, with a kitchen, with a total area of 12 square *sagenes*, i. e. 54 square metres.

9. Separate exits should be provided everywhere, as well as water-closets, and an effective system of water-supply against fire.

10. The drainage of the water-closets and sinks should be connected with the town system of sewers.

11. The heating system is supposed to be that of steam at low pressure with ventilation. Special electric light for the building, entirely separate from all connection with the street. Indicate the sites for boilers and machines.

12. Roofing, ceilings, floors (excepting the stage floor), partitions, and fittings for boxes to be fireproof.

13. The interior decoration to be unostentatious.

14. Frontages to be of bricks, with ornaments, but without stucco.

15. The cost of the building should not exceed R. 450,000 i. e. about £48,000. In order to base calculations for the said cost the price of the cubic *sagenes* (9-71 cubic metres) is fixed at R.55 (about £6). In the above amount of £48,000 the expenses relating to heating, ventilation, water-pipes, electric-lighting, and the machinery of the stage are not included.

16. The designs should include plans of each story, as well as of the frontages, on the Wladimirsky, Foundoukleevsky and Theatrale streets, a longitudinal section, two transverse sections, and an estimate of the whole, with an explanatory notice. The scale to be a hundredth of a *sagenes*. The designs should reach the Imperial Society of Architects (Quai de la Moika, 83) not later than the 3-15 December, 1896, at 7 p. m.

Competitors not living in St. Petersburg may forward their designs by post as late as the above-mentioned date, in proof of which they are required to send the Post Office receipt giving the date when the designs were posted.

17. Premiums will be awarded to the amount of R. 2,500 (about £280) for the first; R. 1,500 (about £160) for the second; R 1,000 (about £120) for the third; R. 700 (about £76) for the fourth; and R. 300 (about £32) for the fifth.

18. The designs selected for awards will become the property of the Municipal Council of Kieff.

The said Council reserve to themselves the right:—

(*a*) To choose from amongst the premiated designs awarded either any one, or any part of any one, which they may deem desirable.

(*b*) To employ to carry out the work either the author of the design or any other person, and to pay such person accordingly.

19. For any particulars not here specified intending competitors should refer to the Rules for the Conduct of Architectural Competitions issued by the Imperial Society of Architects of St. Petersburg on the 28th of March, 1895.

20. The jury will be composed of the following members: Professors N. L. Benois, R. A. Goedicke, and the Count P. J. Suzor, Architect-Academician, Honorary Members of the Imperial Society of Architects of St. Petersburg; Messrs. A. R. Goeschwendt, K. J. Maevsky, P. O. Salmonvitch, Architects, and K. G. Preiss, Architect-Academician. They will have as assessors three persons to represent the Municipal Council of Kieff, the said persons to be chosen by that Council.

There is a curious similarity between the Suggestions for the Conduct of Architectural Competitions which were sanctioned by the Royal Institute in 1892, and those issued by the Imperial Society of St. Petersburg. The differences are few. While the Institute suggests that the promoters of an intended competition should, as their first step, appoint one or more professional assessors, architects of established reputation, the Imperial Society provides for the appointment as assessors to the architects of persons such as sculptors, engineers, physicians, teachers, etc., the number of those members not to exceed a third of the total jury. Both Societies agree, of course, that every promoter of a competition and every assessor engaged upon it should abstain absolutely from competing and from acting as architect for the proposed work. But according to the Royal Institute, the duty of assessors should be, amongst others, the paramount one of drawing up the particulars and conditions as instructions to competitors, and of advising upon the question of cost; while the Imperial Society only admits of those instructions being sanctioned by the jury, after having previously been framed by the promoters.

Clause 4 of the Russian scheme suggests that the conditions of the competition should only bind the competitors to produce sketches with approximate estimates; and clause 6 invites the promoters of a competition to determine the number and kind of plans and drawings, their scale and finish. Both these clauses are very much in accordance with the Institute suggestions. But the Imperial Society adds another condition to these, viz., that the cubic unit should be specified in the programme of the competition, as well as the cost of the unit.

The Imperial Society has a clause which relates to the period during which the designs should reach the jury. It allows of the designs being forwarded by post in a manner which has been heretofore specified.

While the Institute is in favour of the designs being numbered by the promoters in order of receipt, the Imperial Society rules that each design shall bear a motto, the name and address of each competitor being indicated in a sealed envelope bearing on the outside the motto chosen for the design.

The Imperial Society's rules say nothing of the three ways in which, according to the Institute, competitions should be conducted. They suggest that besides the premiums, which should always be awarded to the best designs, there should be provided a certain sum of money to enable the promoters to purchase designs which, although interesting, did not secure a reward.

Clause 9 of the Institute Suggestions has no analogy in the Russian scheme; but while the Institute says that it is *desirable* that all designs submitted in a competition should be publicly exhibited, the Russian scheme makes of such an exhibition a condition *sine qua non*.

The awarded designs become, according to the Russian rules, the property of those who promoted the competition. Both Societies agree in the expression of their desire that the architect whose design may be selected as the best should be employed to carry out the work.

Although I am not personally in favor of competitions, I cannot but hope that our British architects will avail themselves of the opportunity offered by the town of Kieff. There cannot be anything more interesting to an architect than to conceive the plan of a theatre; and the appeal addressed by the Municipal Council of Kieff through such a channel as the Imperial Society of St. Petersburg should be fully responded to.

SKY-SCRAPERS FROM A FIREMAN'S STANDPOINT.

CHIEF BONNER, of the New York Fire Department, has objections to sky-scraping buildings which grow in proportion to the growth of the buildings themselves. He states that if they should eventually reach a height of 500 feet it would not cause him the least surprise. He thinks that the steel-cage principle, which is the basis of their construction, renders the stories independent one of the other, each story carrying its own weight. The space of ground the foundations cover, according to law, must be in proper scientific proportion to the height and weight of the walls, which can be carried, under the present system, to a great height; and, as they are mere brick or stone casings, are not as solid and heavy as of old. The partition walls and flooring are of hollow terra cotta bricks cemented together, which have proved a great advantage in the matter of lightness and enable the structure to be raised to the height of twenty stories or more and still conform to the law in regard to

height, weight and footings. Another and very important advantage is to be added to this: As the walls are of skeleton construction and new materials being reduced, through a very active competition, to a low price in the market, there is a probability of a still greater reduction, as new building material is being manufactured which is even lower in price than terra cotta. In a recent interview on this subject Chief Bonner said:

"The Fire Department considers the sky-scraper a possible scource of danger to its occupants and neighbors. A sky-scraper building, rented exclusively for office purposes, is fireproof in the sense that the woodwork, fixtures and wooden furniture in the various rooms could not cause a sufficient degree of heat, in case they caught fire, to penetrate the cement and terra cotta work that covers and protects the steel frame of the building. The law requires that the steel work must not be left exposed. So long, therefore, as the steel work, on which the stability of the building depends, cannot be reached and warped by heat, the structure may be called fireproof. There is, however, one danger that must be considered. The outbreak of fire in the offices on one floor would naturally result in the combustion reaching other floors. The fire would follow the steam-heating pipes and spread in that way. Now, smoke is as dangerous to life as flame is, and suppose a fire in one the top stories of one of these tall buildings to have gained some headway, one of the most important things to do would be to reach the roof and open ventilators to let the smoke escape. It would not be so easy to reach the roof of a twenty-five-story structure with the elevator service cut off by dense smoke above. The elevator shafts themselves would be a source of danger in case of fire, as they would act simply as flues or conductors for smoke. And, as the stairways in mostly all the tall buildings are constructed close to the elevator shafts and pass by the latter at every landing, it follows, that the stairs would become impassable as well as the shafts. Smoke from fire in lower stories would quickly reach the upper ones in this way, and, as elevators and stairs are the only means of escape from these floors that are above the reach of the department's appliances, the peril of the situation is obvious. In our opinion the tall building should have its stairways constructed as far away from the elevator shafts as possible. There should be two distinct avenues of escape from the building in case of fire. I have said that the term 'fireproof' may fairly apply in the case of buildings occupied only as offices. But, suppose that the constant increase in the number of sky-scrapers causes a diminution in the number of available tenants who want office room only? This I think is a very possible result, and it will naturally have the effect of filling many rooms in the buildings with tenants engaged in mercantile pursuits. The owners will rent to such tenants as they can secure. Thus there will be quantities of inflammable materials stored within the walls, and an outbreak of fire more probable and vastly more serious. Some of the big buildings have already given up their grounds floors to mercantile business, and the tendency in this direction seems to grow. It is entirely different to have a fire break out among merchandise than to have one in an office, with its few desks and chairs. In the former case a degree of heat may be generated sufficient to reach and warp the steel cage frame and induce a collapse of the building.

"Buildings exceeding 125 feet in height are beyond the reach of the Fire Department's best efforts. In our opinion 125 feet is the limit of height consistent with safety. If the sky-scrapers are to continue to soar higher and higher, a law should be passed making it mandatory for the owners to furnish their buildings with first-class machinery for extinguishing fires and to maintain skilled men to operate it. It has been said, and truly enough, that the Fire Department is paid to protect property from fire. But, as I say, there is a limit to our powers.

"At present there is no law to compel owners of sky-scrapers to provide apparatus on their premises. It is only when a modification of the original building plans is applied for that the Board of Examiners of the building Department exacts, as a *quid pro quo*, a stipulation that the building shall be equipped with fire appratus. But we do not believe that such stipulations are complied with in the sense in which they are meant, nor can the Board of Examiners enforce them, as there is no law covering the case. It is merely a question of good faith on the part of the owners. Such appliances as are provided are not, we believe, first-class, nor do they receive any regular care. Besides they are merely in charge of the janitor or his staff, who are not trained or skilled in their manipulation. Hence they would prove practically useless in an emergency.

"What the department considers necessary in this connection, in view of the existing and future probable height of 'sky-scrapers,' is that a law should be passed containing the following provisions: All present office buildings, the height of which exceeds 125 feet, should be required to be provided with steam pumps, standpipes, hose and hose connections. There should be a sufficient pressure of steam up at all hours, day and night, to force the water to the uper floors, and to run at least one elevator car at night. The owners of the building should employ experienced men to work the machinery. These men, who should be continually on duty would be able to check a fire, pending the arrival of our apparatus. The danger of smoke cutting off the elevator shaft would thus be minimized, and the firemen enabled to ascend quickly to those parts of the building which otherwise would practically be inaccessible.

"The power to insist upon these precautions being observed should bs vested in the Board of Examiners of the Building Department. The Fire Department should have in its discretion the approval of the appliances when put in place, and it should also be vested with the right of periodical inspection of them. As long as these precautionary arrangements are lacking in a building above the height I mentioned, I consider that it constitutes a menace to surrounding property, and that it may justly be regarded in the light of a public nuisance."—*Architecture and Building*.

NOTES & COMMENTS.

IF those who remember the splendid condition of the Pt. Lobos Avenue when used as a drive to the Cliff House in former years, will make the comparison with the present state of that avenue they would surely blame the commissioners of the Golden Gate Park for the neglect of the

avenue, as its present condition can most truly be called disgraceful.

If the Park Commissioners cannot do better in the future with the trust than they have in the past. The avenue should be restored to the city authorities and let the street superintendent try his hand at reform.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

COMPETITIVE plans for the Montana Capitol, W. J. Cuthbertson, Architect.

THE Architects of the I. O. O. F. Crematory, published in our last number, should read "Stone & Cahill and T. P. Ross," as it thus appears on all the drawings. The mistake was due to an oversight on our part entirely, for which Mr. Cahill is in no sense responsible.

BOOKS AND PERIODICALS.

CHARTS FOR LOW PRESSURE STEAM HEATING—for the use of engineers, architects, contractors and steam fitters by J. H. Kinealy, D. E. Professor of Mechanical Engineering, Washington University, St. Louis, Mo.

Publishers by Spon & Chamberlain, 12 Cortland street, New York, London, E. & F. N. Spon, 125 Strand, price one dollar.

These charts cannot fail of being a great help to the architect and engineering in saving time consumed in making calculations. The author remarks in his introduction, while he hopes that the charts will be of some value to engineers, they are published more especially for the use of architects and contractors.

SWEET PEA REVIEW a handsome booklet of thirty-two pages containing complete classification in color groups, according to type, with recommendations for the expulsion of the least desirable sorts. Compiled from critical notes made during Sweet Pea growing season of 1895-96—with comparative chart and numerous illustrations. Price twenty-five cents. Published by the Sunset Seed and Plant Co., Sandsomé street, San Francisco.

Any one wanting information about Sweet Peas would do well to read this Review, as they will be astonished to find how little they know upon the subject.

LIPPINCOTT'S Magazine for November contains "An Interrupted Current," a complete novel by Howard M. Yost. This story is founded upon incidents produced by the telephone and proves very interesting though rather improbable. The usual number of short articles make a very interesting number.

THE ARCHITECT'S DIRECTORY for 1896-97—containing a list of the architects of the United States and Canada, Classified by States, Towns, with the architectural associations to which they belong indicated against each name. Prepared with the greatest care to secure accuracy both of names and location. Together with a classified index of prominent dealers and manufacturers of building materials and appliances. Published annually by William T. Comstock, 23 Warren street, New York. Price one dollar.

No. 4.

SOME RESULTS OF SANITARY REFORM.

ONE of Lord Beaconsfield's sayings so it is said was "The health of the people is, in my opinion, the first duty of a statesmen."

And our humble opinion is the same. The health of the people involves, we may say everything with which a statesman has to deal. There is not a single move he makes that does not in some shape or manner affect the people's health.

For example—the submission to arbitration of the Venezuelan Boundary dispute just agreed upon will likely do away with the bad health of many British soldiers who would otherwise be afflicted with cholera or yellow fever or whatever disease usually attacks white residents dwelling in such tropical countries. The policy of "protection" which may possibly be inaugurated under the reign of the incoming administration would undoubtedly affect the health of the operatives who will be compelled to work long hours in the factories which are now under process of reopening.

The method of social economy kept in vogue by our statesmen no doubt affects the health of the number of despondent suicides of which we read daily in our newspapers—and to come down more particularly to the subject matter of these articles; the statesmanlike efforts which compel our citizens to curtail their rent account and leave the healthy house vacant so as to huddle in close quarters in the old unhealthy tenements for want of money are responsible for a large amount of the unhealthiness of our people witnessed by the inordinate number of physicians employed to counteract the results. However the provision of healthy homes and proper sanitary urban arrangements no doubt will relieve much of unhealthiness and sickness.

To those who are of what is called a *practical* turn of mind the following excerpt from the Government Report of "Housing of the Working People" which we are taking as our text, giving us a very queer reason why we should keep the laboring classes healthy, must commend itself.

"Sir James Paget, the distinguished English physician, says the statistics of friendly societies and other similar bodies favor the belief that the whole population of England between 15 and 65 years old in each year work 20,000,000 weeks less than they might if it were not for sickness. Estimating those for the domestic, industrial, and agricultural classes as numbering 7,500,000 he puts their loss at £11,000,000 ($53,531,500) annually. "No one who lives among the poor can doubt," says he, "that a very large proportion of the sickness and loss of work which one sees might have been prevented." He reckons this preventable proportion at one-fourth. In such case the loss that is inflicted on the working class must be nearly £3,000,000 ($14,599,500) yearly. One entirely preventable disease, typhoid fever, causes, he calculates, an annual loss of 230,000 weeks of work to those who survive it.

"The royal commission on the housing of the working classes, 1885, speaking of the housing of the poor in the low parts of London, say that the statistics of annual disease consequent upon overcrowding would not convey the whole truth as to the loss to health occasioned by it to the laboring classes. Some years ago the London board of health instituted inquiries in these low neighborhoods to see what was the amount of labor lost in the year, not by illness but by sheer exhaustion and inability to work. It was found that upon the lowest average every workingman or workingwoman lost about twenty days in the year from simple exhaustion.

"It is very evident, therefore, that no matter how much we may glean from comparative death rates as to the results of sanitary reform, they do not tell the whole story. There are thousands of cases of poor health and depressed vitality which are not followed by death. The improvement in the death rate is, however, the surest available gauge because it is the most tangible."

The point of view of considering health only as a factor in producing wealth and luxuries is assuredly a very low one to take; health is sufficiently good for its own sake to need no other arguments.

The argument adduced is moreover fallacious; for the working class loses no time by any of its members being sick, for there are always plenty of idle ones to take the sick one's places, and it is no loss to the community, for the product is so great that everybody is amply supplied with all they want, only a great deal happens to be in the store houses instead of in use; a few weeks off, even as many as twenty million in the year, cuts no figure—the only matter of regret is that those weeks cannot be spent pleasurably instead of on a sick bed, this is the part of it that is being remedied by sanitary reform.

The Report gives a number of interesting tables of statistics showing the results of Sanitary Reform in the way of reduced general death rate attendant on the less density of population per acre—the less density of population per house and per room.

"The death rate of Glasgow, when the improvement trust commenced operations (1871), was 32 per 1,000; in 1892 it was 22.8 per 1,000 for the extended city, and for the old area 23.6."

Study of these tables—which we have not space to publish in these articles—leads to the conclusion that there is an undoubted relation between overcrowding either within dwellings or on ground space, and death rates.

"Obviously the percentage of the total population living in tenements of one room is a fact of the greatest importance. It must have a close relation to physical health. The table shows that generally speaking the highest death rates are found in the towns which show the largest precentage of the population living in one-room tenements. Another column of this table shows the average number of persons living in each one-room tenement. These averages quite generally follow the death rate, the highest death rate being found in the towns with the largest number of persons in one-room tenements. Again, the town which has the smallest percentage of the population living in tenements of five rooms or upward has the highest death rate, and so on throughout the group of the four towns which have the high death rates. * * This table exposes the tremenous hygienic influences of over-crowding. Generally speaking it proves that the most densely populated tenements are connected with the highest mortality and vice versa."

The necessity of preventing overcrowding by force is to be deplored but still it is better than nothing; and is the only way to do until a better state of society evolves itself.

Chapter V of the report is devoted to Sanitary Aid Societies and their work and commences thus wise:—

"Some of the most prominent witnesses before the English royal commission on the housing of the working classes, of 1885, stated their belief that existing laws were ample for dealing with all sanitary questions if they were properly enforced. The same complaint has often been heard in different cities of the United States. Sanitary law and sanitary administration are two quite different things, and the one does not always follow the other in natural sequence.

"It must be observed, however, that expediency plays a a certain part in sanitary administration. To have rigidly enforced at the outset stringent laws, such as exist in New York, for example, would have arrayed the property owning element in opposition and might have brought about a repeal. As owners of unhealthy property grow accustomed to greater pressure, and as tenants become more exacting in their demands, the task of sanitary authorities becomes easier. In the beginning an insistence on conformity to legal prescriptions (many of which were looked upon as unnecessarily strict) would have been unwise and might have blocked the way to progress.

"Sanitary authorities, like all other administrative bodies, if left to themselves, are apt to become conservative. A little stirring up occasionally is usually a good thing, and the interest of enlightened citizens, organized into associations for extending aid and cooperation, is especially useful.

"The testimony of such veterans in sanitary science as Dr. Russell of Glasgow, Dr. Shirley Murphy of London, Dr. du Mesnil of Paris, and Dr. Janssens of Brussels, as well as of a host of American experts, goes to show that the ignorance and apathy of the poor, for whose benefit work has to be done, are among the greatest obstacles met with in the discharge of duty. Sanitary aid societies may do much to help the authorities by acting as intermediaries during the period in which fear of the possible consequences of communicating a knowledge of the existence of nuisances or other insalubrity still holds sway. Direct contact between the poor and boards of health being once established, there is no longer the same necessity of intervention. An important fact is that without the good offices of the intermediary, cooperation is with difficulty established.

"A fundamental need, which has so far received but scant recognition in this country and England, but which is at least recognized in the educational systems of France and Belgium, is instruction in the elements of household hygiene in the public schools. The effects of this kind of teaching would soon become apparent, and in the course of a generation or two would powerfully react upon sanitary amelioration. Dissatisfaction with unhealthy surroundings would be cultivated, and the knowledge of what was good and wholesome would make of the rising generation a far more exacting tenant class than their elders.

The principal functions of sanitary aid associations may be summarized as follows:

"1. To organize and mold popular sentiment in favor of wise sanitary legislation.

"2. To assist boards of health in the discharge of their duties by bringing to their knowledge the existence of insalubrious conditions in districts where they are most likely to occur and which need more or less constant watching.

"3. To encourage sanitary authorities to do their whole duty by supporting them in difficulties arising in critical cases, and in bringing proper pressure to bear wherever there seems to be an inclination to relax effort. The creation of public opinion to sustain sanitary authorities in their work is also an important duty.

"4. To assist in the education of the poor on sanitary questions; teaching them that there is an authority to appeal to against nuisances, instructing them in procedure; leaving in their homes a printed list of elementary hygienic observances, and such literature as is occasionally distributed by boards of health, giving suggestions on the care of infants, and the conditions to be observed in the treatment of persons in cases of infectious diseases. Education in sanitary as well as in all other matters lies back of reform. The knowledge of improved conditions begets a desire for their enjoyment.

"5. The publication from time to time of facts gleamed from official sources which tend to act as a salutary warning against residence in unhealthy neighborhoods. An example of what is meant is the inquiry made by Dr. Thresh into the causes of excessive mortality prevailing in District No. 1, Ancoats, Manchester, England. Taking the returns of deaths from the health and hospital reports he was able to show the true death rate for the whole district. It was proved that only in a few blocks was this less than 40 per 1,000, while in some places it was 50, 67, and even 80 per 1,000. The publication of these facts aroused the more intelligent working people who were residents of the neighborhood to form 'sanitary and healthy home associations,' as they called them. They were awakened from their apathy, and in a short time the rehabilitation of the district was effected. Dissemination of knowledge in relation to death rates and causes of sicknesses for specified localities is of great practical value. Not only is public opinion aroused, but interested opposition is left powerless to thwart progressive action. Public opinion, when informed, will always sustain sanitary authorities in the application of drastic remedies. To make healthy and keep healthy existing buildings is a work of scarcely less importance, though much more difficult to accomplish than the safeguarding of new structures. Voluntary associations of individuals cooperating harmoniously with the regularly constituted authority may powerfully assist in promoting health and good housing among the masses. In sanitary matters eternal vigilance is the price of safety.

"All well organized boards of health seek to disseminate among the poor information relating to the care of children and the maintenance of a favorable hygienic environment. The New York board of health does considerably more. It maintains a special summer corps of physicians whose duty it is to visit every tenement house, beginning in the latter part of June, for the purpose of giving medical advice and treatment, distributing literature, giving hints for the care of infants, and searching out insanitary conditions. There are fifty of these medical gentlemen, forty-eight doing duty in the tenement house district, while two are assigned to the hospital boat and to charitable excursions undertaken for the benefit of mothers and children. Personal visitation of this kind is far more effective than the distribution of literature alone. Attention is usually paid to oral advice from those professionally competent to give it, while heed is not always accorded to even the most useful hints which well edited circulars may contain. A word or two often suffices to correct household defects unfavorably affecting

the health of occupants which were regarded hitherto with complacency."

There is no doubt a little too much paternity or rather maternity about all this—it is no doubt all necessary, but one cannot help thinking that a few municipal workshops well equipped and hygienic—where the heads of families could get constant work at good pay, would sooner do away with unsanitary conditions and cost no more than the army of Sanitary Inspectors and Sanitary Aid Societies—which now potter about trying to cover up the sores which all the time fester below.

Although these Sanitary Aid Societies have done much good, in consequence of their being so many disconnected ones, (in New York there are probably thirty associations engaged in ascertaining infractions of the laws and otherwise aiding the local authorities,) their work being thereby unsystematic, the result of their labors are not what it should be. More practical results, we believe would be obtained by giving an official character to them by the City organizing in each precinct a committee which shall choose a head man, who shall be recognized as a city officer and shall report to the Board of Health all infractions of laws, all complaints, bad state of any streets and sewers and all other matters appertaining to the public welfare.

The closing sentence applies here with good force:

"Vigilance is necessary to maintain a proper hygienic standard in the housing of the poor. From the very magnitude of their work the regular sanitary administrations find themselves crippled from lack of resources and of inspectors sufficient to fully accomplish the work. The organization and maintenance of such societies is a necessity in order to secure the wise enforcement of health laws and the advance of sanitary education in any city. The prime conditions of success are hearty cooperation with regularly constituted authority, and an intimate knowledge of the conditions and needs of the homes of the poor."

COMPRESSED AIR FOR STREET CARS.

THE MANHATTAN Elevated Railroad of New York has authorized an air-power company to place one of its motors on one of its lines to run on schedule time and to draw a train of five cars. If it should be a success in this trial the Manhattan Company will consider the use of air motors on the entire system. The compressed-air locomotive or motor is little more than a long, black cylinder, similar to the boiler of the present locomotive, with the cab at one end. There will be no smokestack, no tender and no dome. The only protuberances on the cylinder besides the cab will be the whistle and the sandbox. The air power company claims that it can draw loaded trains more rapidly, smoothly and safely than is done by the steam locomotive, and at a decrease in operating expense, and points to its cars now running on the 125th street branch of the Third avenue cable line, in New York City, as an example of what it can do. The company avers that the public and the railway officials are more than satisfied with the cars, and that it is only a question of time when compressed air will supersede steam, cable, electric and horse power on city street railways.—*Mining and Scientific Press.*

A NEW PROCESS FOR THE MANUFACTURE OF STEEL.

A NEW process for the manufacture of steel, invented by B. Stockman of Manchester, England, is claimed to be a success. The process involves a combination of both the Bessemer and the open-hearth methods of manufacture, and it is a basic dephosphorizing system. The molten phosphoric iron is brought into contact, in a converter or similar vessel, with dephosphorizing agents—nitrate of soda, common salt and titanic iron sand being the chief ingredients—and, after a contact of only three minutes, the metalloids are practically eliminated. The metal is then poured into an open-hearth melting furnace, where it is treated for about two hours, during which time the dephosphorization and desulphurization are completed, aud the carbon is added in the usual way, as spiegeleisen or ferro-manganese. The steel produced by this system has been tested by Kirkaldy of London and Nash of Sheffield, and the results are said to be satisfactory. It appears to be adapted to the production of steel of any degree of hardness, and, as it only occupies about 2¼ to 2½ hours, it is comparatively inexpensive.—*Mining and Scientific Press.*

TENDERS TO BE RECEIVED.

Treasury Department, Office Supervising Architect, Washington, D. C., November 9, 1896. Sealed proposals will be received at this office until 2 o'clock P. M. on the 22d day of December, 1896, and opened immediately thereafter, for all the labor and materials required for the low pressure, return circulation, steam heating and ventilating apparatus and power boiler for the U. S. Marine Hospital Building at Port Townsend, Washington, in accordance with the drawings and specification, copies of which may be had at this office or the office of the Custodian at Port Townsend, Washington.

Each bid must be accompanied by a certified check for a sum not less than 2 per cent of the amount of the proposal. The right is reserved to reject any or all bids and to waive any defect or informality in any bid, should it be deemed in the interest of the Government to do so.

All proposals received after the time stated will be returned to the bidders.

WM. MARTIN AIKEN,
Supervising Architect.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

RIGHT TO PARTY WALL ACQUIRED BY LONG USE.—Where an adjoining owner and his predecessors in title had used for twenty years a wall, part of which was wholly situated on the neighbor's land, for the support of their building, an easement in such land for such purpose was created by such long use, and this right becomes an appurtenance to the estate and passes to the grantees.

Barry v. Edlavitch, Ct. App. Md., 35 Atlantic Reporter, 170.

ALLEGATION OF OWNERSHIP OF LAND NECESSARY TO LIEN.—Under the law providing that one furnishing labor and material for any structure under a contract with the owner of the real estate shall have a lien upon it for the value of the labor and materials furnished, a complaint in an action to enforce such lien which fails to allege that the party sued was the owner of the land on which it was sought to attach the lien, or set out that such party had any interest in it, is fatally defective.

Knapp Elec. Works v. Mecosta Elec. Co., Sup. Ct. Mich., 68 Northwestern Rep. 245.

DISCREPANCIES IN PLANS AND SPECIFICATIONS.—Where the plans and specifications of a building were accessible to the builder before he made the contract, and an examination of them would have shown that there were apparent discrepancies in them, he is bound by a provision of the contract that if any discrepancies are found to exist between the plans, working drawings and specifications, the architect shall decide as to their true intent and meaning. And the fact that such architects drew the plans and specifications, and were to receive a compensation of five per cent of the total cost of the building, will not warrant an inference of fraud in their decision.

Kelley v. Muskegon, Sup. Ct. Mich., 68 N. W. Reporter, 282.

DESCRIPTION OF PROPERTY FOR LIEN.—A mechanic's lien for construction of foundations for a mill and boiler house sufficiently identifies the property, under the law of Pennsylvania, by stating that the buildings are on the grounds of a certain company, in a certain town, and giving the dimensions of the mill and foundations.

Safe Deposit, etc., Co. v. P. & C. Iron & Steel Co., Sup. Ct. Penna. 35 Atlantic Rep. 229.

BUSINESS MOSAICS.

If you have not made a visit to the rooms of Mr. M. S. James in the Flood Building and inspect his stock of plumbing work in the way of porcelain and porcelain line work you have missed a sight worth seeing. Mr. James is the Pacific Coast Representative of the J. L. Mott Iron Works, New York. This firm is so well known throughout the country for the improvements made from year to year in sadiatry plumbing that one must make a frequent visit in order to keep posted on what is being done in this line.

Family friend—Well, how's little Willie? We don't see as much of you as we used to. WILLIE (shyly)—No; I'm in long trousers now.—*Truth.*

W. P. Fuller & Co., having such perfect machinery for the manufacture of paint, that it is no wonder they produce a pure article, as pure material well ground will produce pure paint. The new wall finish "Duresco" is described as a very desirable article producing a finish upon walls that can be washed and still preserve its face uninjured, at the same time binding the wall even when disposed to crumble.

Mrs. Casey—Joost see little Mary makin' love to little Moikey. MRS. KERRIGAN—God hilp the poor men when she grows oop. She makes love like a widder already.—*Puck.*

N. & G. Taylor Company, Philadelphia, Pa., as manufarturers' agents for the Pancoast Ventilator, issue a striking circular showing a half-tone picture of a 66 inch Pancoast Ventilator 11 feet in diameter, which, with one of 84 inches, weighing over 1000 pounds and nearly 14 feet in diameter, were lately sold to the Crittenden Mfg. & Roofing Company of Minneapolis, Minn.

Customer—Do you keep the CALIFORNIA ARCHITECT AND BUILDING NEWS? STATIONER—No, we sell it.

Joseph Budde, manufacturer of sanitary appliances will be found at his old quarters, 575 Mission street, he invites the public to visit his show room as his motto is "First class work, low prices and two years guarantee for all my work," what more can be asked of any dealer.

She—Will you come home to dinner with me? Oh, no! I have my business suit on. SHE—Well, what of that? Don't you mean business?

No material has so strong an affinity for iron and steel as pure, soft flake Graphite, and for bicycle chains and sprockets there is nothing equal to it. The Dixon Crucible Co., Jersey City, N. J., selects its choicest material from unlimited stocks, and after analyzing all other cycle chain lubricants in the market that it could find, does not hesitate to say rhat Dixon's No. 691 Cycle Chain Graphite is absolutely without an equal for preventing rust and wear of chain and for insuring ease and comfort in riding. Mr. Tom W. Winder, the man who rode 21,000 miles around the borders of the United States, was offered all sorts of chain lubricants, and Dixon's was found superior to anything offered. He says: "It saved me much hard work, as its application never failed to cause an easy running chain." No. 691 is the improved shape, and fits the tool-bag easily. If your dealer does not keep it, send ten cents for a sample, and you will never regret it. Dealers will receive a sample free of charge by sending their business card.

CITY BUILDING NEWS.

Baker near Sacramento. Alterations and additions; owner, Mary E. Finney; architect, A. J. Barnett; signed, Oct. 19; filed, Oct. 21; cost $2624.

Bryant near 3rd. To build engine house; owner, City of San Francisco; architect, C. R. Wilson; contractor, A. Dahlberg; cost $6097.

Brannan near 5th. To build; owner, Heme M'fg. Co.; contractors, Campbell & Pettus; cost $1200.

Bush near Kearny. Additions and alteration; owner, City of San Francisco; architect, C. R. Wilson; contractor, A. Campbell; cost $2788.

Bush near Jones. Alterations and additions; owner, L. Aurbach; architect, Jas. E. Wolfe; contractors, Blanchard & McDonald; signed, Oct. 12; filed, Oct. 14; cost $1040.

California near Larkin. Alterations and additions; owner, William J. Helm; architect, W. H. Hamilton; contractor, William Bell; signed, Oct. 8; filed, Oct. 10; cost $1829.

California near Baker. To build; owner, Jeremiah Lynch administrator of estate of Eudora V. Smith; architect, J. H. Jordan; contractors, Elder & McLaughlin; signed, Oct. 15; filed, Oct. 20; cost $3620.

California and St. Mary. Additions; owner, A. Grapo; contractor, J. E. Dunphy; signed, Oct. 20; filed, Oct. 20; cost $1300.

California near 25th Ave. To build; owner, Francois Bragg; architect, John Godart; contractor, W. R. Kenny; signed, Oct. 30; filed, Oct. 30; cost $1800.

Clay and Webster. Cold storage apparatus; owner, Cooper Medical College; contractor, Vulcan Iron Works; signed, Oct. 8; filed, Oct. 10; cost $1500.

Clement and 4th Ave. To build; owner, C. B. & Louisa M. Ryder; architect, John M. Curtis; contractor, C. Anderson; signed, Oct. 14; filed, Oct. 20; cost $4670.

Devisadero street. To build; owner, E. R. Myrich; architects, Shea & Shea; contractor, J. D. Hannah; signed, Oct. 21; filed, Oct. 27; cost $2755.

Eighth Ave. near Clement. Cottage; owner, Geo. F. Carway; contractor, Ed. Girley; signed, Oct. 7; filed, Oct. 8; cost $1656.

Eighteenth near Sanchez. To build; owner, Mrs. Elizabeth Wallan; contractor, C. G. Gillespie; signed, Oct. 7; filed, Oct. 8; cost $2000.

Ellis near Webster. Alterations and additions; owner, Richard and Emma Ilatele; architect, A. Hildebrand; contractor, L. D. Frichette; signed, Oct. 21; filed, Oct. 22; cost $1462.

Fifth near Stevenson. Brick and terra cotta work five-story brick; owner, John F. Royd; architects, McDougall & Bro.; contractor, Thos. Butler; cost $7540. Carpenter work; contractor, A. Jackson; cost $9282. Cast and wrought iron; contractor, James McCrosson; cost $4031. Plumbing, etc.; contractor, W. F. Wilson; cost $1997.

Folsom near 20th. To build; owner, Michael J. O'Reilly; architect, Jas. S. Brady; signed, Oct. 19; filed, Oct. 20; cost $2800.

Folsom street Wharf Pier 12. Sheds and improvements; owner, Board of Harbor Commissioners; contractor, Thomas Day & Sons; cost $6649.

Fremont near Market. Carpentry, mill work, etc.; owner, L. Guggenheim & L. Mack; architects, Percy & Hamilton; contractor, Thos. McLachan; signed, Nov. 9; filed, Nov. 11; cost $11,090. Brick, terra cotta work, etc.; contractors, Richardson & Gale; cost $1874. Excavating and removal of old building; contractors, Keatinge, Leonard & Ransome; signed, Nov. 9; filed, Nov. 11; cost $5340. Iron and street work; contractor, Dyer Bros.; cost $6130.

Golden Gate Ave. near Van Ness Ave. To build; owner, John De Witt; architects, Smith & Freeman; signed, Nov. 9; filed, Nov. 12; cost $1760.

Guerrero and Market. To build; owner, M. C. Taylor; contractor, B. R. Van Dusen; signed, Nov. 7; filed, Nov. 7; cost $11,300.

Houston near Jones. To build; owner, A. Paladini; contractor, H. R. Schmuckert; signed, Oct. 28; filed, Oct. 29; cost $8517.

Illinois near Napa. Alterations and additions; owner, Jas. F. McDonald; architects, Herman & Swain; contractor, C. J. Anliwiller; signed, Oct. 19; filed, Oct. 19; cost $965.

Ingleside Race Tract. Redwood tank; owner, Pacific Jockey Club; architect, T. J. Welsh; contractor, Pacific Tank Co.; signed, Oct. 14; filed, Oct. 16; cost $1408.

Jackson near Sansome. Alterations; owner, D. Ghirardelli; architects, Wm. Mooser & Son; contractor, M. C. Lynch; signed, Nov. 4; filed, Nov. 4; cost $995.

Lake View, block 25, lot 25. Two-story frame; owner, E. H. Bode; architect, W. J. Cuthbertson; contractor, J. W. Fish; signed, Oct. 13; filed, Oct 14; cost $1865.

Larkin near Jackson. To build; owner, Lorenzo M. Perez; architects, Reid Bros.; signed, Oct. 5; filed, Oct. 15; cost $2880.

Laguna and Birch. Alteration and additions; owner, Mrs. M. C. Dresser; contractor, Chas Kuehig; signed, Nov. 10; filed, Nov. 13; cost $1957.

Lyon near Grove. To build; owner, L. H. Cox; contractor, Ed. Cox; signed, Oct 12; filed, Oct. 13; cost $3700.

Lyon near Hayes. To build; owner, L. H. Cox; contracto, Ed. Cox; signed, Oct. 12; filed, Oct. 13; cost $3700.

Lyon near Hayes. Carpenter work, etc., except plumbing; owner, L. H. Cox; contractor, L. B. Schmid; signed, Oct. 12; filed, Oct. 14; cost $7644.

Market and Seventh. Improvements in Odd Fellows Building; owner, I. O. O. F.; architect, E. J. Vogel. Carpenter work; contractor, L. Schmid. Plumbing; contractor, G. M. Eastman. Marble; contractor, J. Musto & Son. cost $2000.

Market near 11th. Three-story brick; owner, City of San Francisco; architect, C. R. Wilson; contractor, Thomas Butler; cost $15,975.

Noe and 23d. To build; owner, Chas. Bardenhagen; architect, E. J. Vogel; contractors, Petterson & Person; signed, Oct. 15; filed, Oct. 17; cost $2849.

O'Farrell near Stockton. Additions to Delmonico; owners, Gutzeit & Malfanti; architects, Pissis & Moore; cost $1000.

Pt. Lobos Ave. and 1st Ave. To build; owner, Margaret J. Wheeland; architect, C. J. Colley; contractor, Ed. Cox; signed, Oct. 31; filed, Nov. 4; cost $6450.

Page and Shrader. Two two-story frame dwellings; owner, J. E. Doolittle; architect, E. J. Vogel; contractors, Petterson & Person; signed, Sept. 30; filed, Oct. 15; cost $4469.

Page and Steiner. To build; owner, Ella A. Judson; architect, R. H. White; contractor, John Furness; signed, Oct. 19; filed, Oct. 20; cost $5585.

Powell near O'Farrell. Plastering work; owner, Geo. D. Toy; architects, Herman & Swain; signed, Oct. 16; filed, Oct. 16; cost $1075.

Powell and Ellis. Electric work four-story brick; owner, Royal Eagle Distilleries Co.; architect, E. Kollofrath; contractor, L. B. Hetty; signed, Oct. 24; filed, Oct. 24; cost $274.

Powell and Ellis. Interior cabinet work; owners, Royal Eagle Dist, Co.; architect, E. Kollofrath; contractors, S. & G. Gump; signed, Oct. 27; filed, Oct. 27; cost $5430.

Post near Stockton. Electric elevator; owner, Improved Order of Redmen; contractor, Fraser Electric Co.; signed, Nov. 18; filed, Nov. 18; cost $3700.

Pt. Lobos Ave. near 11th Ave. To build; owner, Sophia Hansen; architect, Martens & Coffey; contractors, Relt & Ahlgren; signed, Oct. 13; filed, Oct. 16; cost $2700.

Sacramento near Van Ness Ave. Brick work for stable; owner, Claus Spreckels; architect, Reid Bros.; contractor, Rae Building Co.; signed, Sept. 26; filed, Oct. 8; cost $1190 per M. about $2000.

Sacramento near Van Ness. Grading, etc.; owner, J. Z. Pasadus; Architects, Pissis & Moore; contractor, Peacock & Butcher; cost $2995.

Sacramento near Van Ness. Carpentry, tinning, etc.; owner, J. Z. Pasadus; architects, Pissis & Moore; contractor, Robert Smilie; cost $9887. Sandstone contractor, J. D. McGilvray; $4500. Plumbing; contractor, Ickelheimer Bros.; $2449.

Second Ave. near Clement. Cottage; owner, James McElroy; contractor, W. W. Rednall; signed, Oct. 25; filed, Oct. 25; cost $1650.

Sixteenth and Albion. Plumbing, gasfitting, etc.; owner, S. Bear; architects, Salfield & Kohlberg; contractors, Ickelheimer & Bros.; signed, Oct. 12; filed, Oct. 14; cost $1185.

Sutter and Hyde. Tiling work; owner, Dr. J. Rosenstern; architects, Salfield & Kohlberg; contractors, Mangrum & Otter; signed, Oct. 24; filed, Nov. 25; cost $2800.

Sutter and Hyde. Glass and glazing; owner, Dr. J. Rosenstirn; architects, Salfield & Kohlberg; contractors, Campbell & Pettus; signed, Oct. 15; filed, Oct. 23; cost $1100.

Tehama near 6th. Alterations and additions; owner, Abbie Middleton and Mary Barada; contractor, F. V. Acker; signed, Oct. 23; filed, Oct. 27; cost $1100.

Twenty-second near Castro. Carpenter work; owner, M. C. O'Shannessy; architect, W. J. Cuthbertson; contractor, W. Plant; signed, Oct. 20; filed, Oct. 22; cost $3065. Electric wiring; contractor, McWhirter Electric Co.; cost $60 50 Painting; contractor, Delos Wilson; cost $320. Plumbing; contractor, M. Fisher; cost $417.

Twenty-fourth. and D. Removal of Casino Building from Park; owner, Stewart Menzies; architects, Townsend & Wyneken; signed, Oct. 14; filed, Oct. 15; cost $2250.

Twenty-fourth and Sanchez. To build; owner, Mrs. Margaret Curtin; architect, C. M. Rousseau; contractor, R. J. Pavert; signed, Oct. 22; filed, Oct. 23; cost $4500.

Twenty-fourth near San Bruno Ave. Cottage; owner, Thomas Doyle; contractor, Allen De Lair; signed, Oct. 18; filed, Oct. 28; cost $1125.

Twenty-fourth Ave. and D street. Alterations and additions; owner, Stewart Menzies; architects, Townsend & Wyneken; superintend, Peter Hamilton; day's work; cost $12,000.

Thirteth near Warren. Cottage; owner, Leonard Haas; architect, C. M. Rousseau; contractors, Sarcander & Thompson; signed, Oct. 27; filed, Oct. 28; cost $1200.

Union near Scott. To build; owner, Mary I. Bradford; architect, A. C. Schweinfurth; contractors, Richardson & Gale; signed, Oct. 17; filed, Oct. 18; cost $2745.

Union nr Scott. Plumbing; owner, Mary I. Bradford; architect, A. C. Schweinfurth; contractor, W. F. Wilson; signed, Oct. 17; filed, Oct. 19; cost $365.

Van Ness Ave. Junction with Lewis street. Wharff construction; owner, Fortana & Co.; contractors, Warren & Malley; cost $15,000.

Waller near Shrader. To build; owner, Mary Paolinelle; contractor, Thos. Vodden; signed, Oct. 17; filed, Oct. 24; cost $2000.

Welsh near 4th. To build; owner, Sarah Green; architect, A. J. Barnett; contractors, R. Doyle & Son; signed, Oct. 16; filed, Oct. 29; cost $5919.

York near 21st. Cottage; owner, Geo. A. Heuer; contractor, H. Grieb; signed, Oct. 14; filed, Oct. 15; cost $2150.

PREMISES OF NEW SAN FRANCISCO POST-OFFICE, AUTHORIZED BY ACT OF CONGRESS, MARCH, 1887.

EXISTING POST-OFFICE BUILDING AT SAN FRANCISCO, CALIFORNIA.

THE attention of architects is called to an advertisement in this number of the desire to obtain an architect on the part of the Trans-Mississippi and International Exposition at Omaha, Neb. As the cost of this Exposition is estimated at $1,000,000, it may be anobject to some of our architects to obtain the situation, though the inducements offered are rather indefinate.

AT THE last meeting of the San Francisco Chapter of the American Institute of Architects it had up for consideration a draft for a bill to be presented to the next Legislature on the subject of obtaining plans for public work, in place of the present absurd and totally inappropriate statute on that subject—which, as all those interested, know, exhibits an entire want of cognizance of an architects status and duties;

the defects of every part of it are so palpable that it needs no further criticism. To show how utterly useless it is, it is practically a dead letter; we have yet to know the first case in which its provisions have been carried out. In the draft for a new law the Chapter has endeavored to look paramountly to the interests of the people; for it will be found that the interests of true architects and of the State are identical.

The principal points of the proposed new law are:—

First—A distinction has been made between architectural and engineering works, between buildings and bridges, etc. In one case the services of an architectural expert is required, in the other an engineering expert; so that there may be no clashing in regard to these matters, such as we find often in national work.

Second—A limit of $20,000 has been placed below which no competitive plans are required, so that a Board or any other authority may appoint an architect or engineer for small work; saves expense both to the people and to the professionals.

Third—Sketch plans and sketch or outline specifications only are required—and none other can be called for, for the reason that these indicate both to a layman and a professional just as much as the most elaborate working drawings as far as selecting the best plan or design goes which can be the only object in having a competition at all. The object of a competition must be to get the best plan, not the best and most experienced architect, for if the latter were the case, competition would be needless, and the architect would be chosen for the work he may have executed.

The report of the expert will show which plans can be built within the appropriation—there is no trouble in making a very close approximate estimate from sketch plans and specifications to an experienced man.

Fourth—The value and number of the premiums have been stated so that uniform conduct may be observed throughout the State, and that first-class architects may put their efforts forwards for the interests of the people, and it is made mandatory because, otherwise, some authority having a low class man picked out as their architect could then by offering nominal premiums shut out first-class men from competing and giving a walk over to their third class man.

The total value of the premiums have been taken at one per cent as being the generally recognized value attached to sketches and for all cost over $200,000 only one-half per cent is taken, because the larger a building is, generally is there less work in proportion, and possibly over one-half per cent might be more than the value of the services rendered.

Fifth—It will be noticed that an expert must be consulted in all cases. The plans generally chosen by Boards without consulting an expert is sufficient evidence of the necessity of this clause.

Sixth—The principle adopted in regard to payment of the chosen architect is, that the buying of the sketch plans is one complete transaction and the appointment of an architect to carry on the building is another. The author of the adopted plan is paid one per cent on the cost of the *entire work when completed* not only on the one appropriation when there may be others needed to complete the work. That completes the Board's transactions with him until such time as the work may proceed.

Seventh—All other plans are returned to their authors at once—the people have obtained all the matter from them that they are justly entitled to when they are used as means of comparison with the successful one—if there are any good points in them to be culled, there is nothing in this law preventing the Board from buying from the owners such points; which should be considered copyrighted till then.

Eighth—The author of the accepted design is made the supervising architect of the structure, for the reason tnat he is the only one who can carry out the design as was intended in his preliminary plans, and his remuneration is made four per cent for his working drawings and supervision, making a total of five per cent when including the one per cent for preliminary plans; because that has been universally conceded to be a fair remuneration of an architect's work from time, one might say, immemorial. It will be noticed that, as preliminary sketches must embrace a design for the whole structure complete, he gets one per cent on the *total* cost of the structure, while the four per cent is only chargeable on so much as may be expended as the work proceeds, which seems eminently just.

Ninth—The necessity for a superintendent of works, who shall be always present on the building, is now so well recognized that no further comment is necessary on the paragraph making his appointment mandatory.

Tenth—The penalty attached to the non-fulfilment of the present statute is making all contracts null and void when said statute is violated. This works an injustice on the innocent contractor and strikes the wrong party. The guilty parties are the officials; and any officials not attending to business on matters such as in question deserve to be deprived of the office which they are manifestly incompetent to fill; any attempt to do this however would meet with determined opposition. So that making *all* of their acts illegal that did not conform to this Law is the next best thing.

The whole bill seems to the point and we hope to see it passed by the legislature, and thus inaugurate an era of better feeling and better architecture in the matter of getting plans for public buildings than is possible under the present abominable and impossible statute.

Else where we give the proposed new bill and the present one for the benefit of our readers.

GOVERNMENTAL ARCHITECTURE.

THE title of "Surveyor of Public Buildings" was given to James Hoban, Superintendent of the Capitol, in 1794, which office he held for twenty-five years. The same title was conferred upon Benjamin H. Latrobe when he succeeded Hoban and became the architect of the Capitol. After Latrobe retired, a Government "Commissioner of Public Buildings" was appointed. But no such office existed after 1830. The Government buildings erected during the first part of the century in Washington and various parts of the country were conducted, somewhat as the capitol was, under the direction of Cabinet officers or Congressional commissions. The buildings comprised a few of the department offices and custom-houses, sub-treasuries, the mints, and a building in Philadelphia for the United States Bank. The latter went out of use with the abolition of the bank. Among those that were retained in use are the Interior Department, the Treasury Department, the Postoffice Department at Washington, the Mint at Philadelphia, and the Sub-Treasury at New York.

It was about the year 1850 that something approaching a system was adopted. The public buildings were then erected under the direction of the War Department, and an office was established under the charge of a major of United States engineers. The plans were made under his direction by architects who simply acted in the capacity of draughtsmen. An officer of engineers was assigned to each building as "Engineer in Charge." Mr. Walter while architect of the Capitol extension, had been charged with making plans for additions also to the Interior Department Building (Patent Office) and the Postoffice, and was later directed to design the extensions of the Treasury Building; all of which, as to exterior, were, in the main, continuations of the old designs. The extension of the Interior Department (generally known as the Patent Office) and Post-office were carried out under his superintendence. The Treasury Building was intrusted to Mr. Young, who was then named the "Supervising Architect of the Treasury Department," and under whose care the south wing of the building was built. This was the commencement of a system of management which has been greatly enlarged and still exists. Mr. Young was succeeded by Isaiah Rogers, of Cincinnati, a very distinguished architect, who had designed the Tremont House, at Boston, the Astor House at New York, the Merchants' Exchange, New York, and the Burnett House of Cincinnati. Mr. Rogers was succeeded by A. B. Mullett, a young architect of Cincinnati of little experience. Under his administration all the Government buildings being erected in the North were put under his sole direction, and civilians were appointed as local superintendents.

During this period of twelve years the Government buildings of New York, Boston, Philadelphia, Cincinnati, St. Louis, and Chicago, and a hundred others of lesser importance, were commenced, including the State, War, and Navy Department building at Washington. The cost of those mentioned was upwards of thirty millions of dollars, and the aggregate cost of all the buildings erected under this architect's administration was over one hundred millions of dollars.

Mr. Mullett was succeeded in office by William A. Potter, a young but experienced architect of New York. He was obliged to finish Mr. Mullett's work, and in the designing of new Government buildings attempted to endow them with artistic beauties, to which the office had before been a stranger. But he found it to be a herculean task to reform its methods of design. He, however, succeeded in leaving his impress upon some of the smaller buildings that were designed during his term, notably those at Covington, Ky., and Fall River, Mass. After a time he resigned in despair, and was succeeded by James G. Hill, of Boston, who had been head draughtsmen. Mr. Hill was entirely at home in the routine of the office, and made some improvements in Mr. Mullett's methods. He was succeeded by M. E. Bell, of Des Moines, Iowa.—*Self Culture.*

CHEAP TELEPHONE SYSTEM.

FOR a fee of from two to eight cents a message, one may talk from even the smallest of Swiss towns over a long-distant telephone system to any part of the country. Of course the Government owns the system.

HOME ARTS IN THE CUMBERLAND MOUNTAINS.

"The makers are the poets; ply your skill,
Coleridge and Southey watch from yonder hill."

HOME ARTS have become so firmly associated with the upper regions of the Albert Hall, where their annual exhibition is held, that many people hardly realize the wide contrast this, their town abode, forms in every respect to one of the most celebrated producing centres of such work, the settlement at Keswick, among the Cumberland mountains. The results of this work are known far and wide, wherever beauty of design and perfection of workmanship are valued, but the workers at home and their work in process (representing as it does a solid national art movement among country folk), are by no means familiar to the many admirers of the beautiful results of these well-spent winter evenings, for few people dare the imagined rigors of the Lake District during winter months. That such imaginings are somewhat foolish, we who live amid the mountain glories of winter know full well; but it is impossible to regret that at *some* time in the year this country should be left to its own resources, and that the boatman and the shepherd with the few others whose homes and toil are of the mountains, should have the hillsides and the tarns to themselves in all their winter beauty. To them it is given to see the sun die down behind Grisedale, with its many hues of orange and crimson reflected in the black ice of Derwentwater; they hear the owls hoot and see the stars come out one by one above snowy Skiddaw—scenes that should call forth all the sense of beauty that is in a man, and enable him to reach unto something in art which is "the expression of man's delight in the works of God." That this *should* be the case, no one can doubt, but that it *is*, is quite another matter, alway excepting unusual dispositions and cases. As a rule, the hardy north-country folk are by no means easily impressed with the beauty of their surroundings; fond of them to a fault, yes—but sensitive to their influences—no; and, indeed, one great reason for the commencement of this pursuit after beauty in the minds of the promoters of this art movement, was to train the eye and open the heart and mind to all the wonderful surrounding beauty of form and color which every season reveals in its infinite variety to the dwellers around mere and mountain.

This may be called the æsthetic aim of our mountain school of art, but its practical object, now successfully attained, was to find remunerative employment for working men and others in spare hours, or when out of work, by teaching them such art industries as can be profitably carried on in their own homes; the payment for such work from the Keswick School is 6d. an hour, and a good workman can easily add £1 a week to his wages by spending his spare time in this way, instead of in that "friendly crack" in the parlor of the "Cock and Dolphin," where the connection with wage-money is subtraction instead of addition.

Our view of the school took place one January afternoon and evening, a view which had been deferred till the permanent building should be established, which, for many reasons, gives an importance and dignity to the work carried on at Keswick. The art work of the classes commenced in 1884, but it was not till the April of 1894 that its abiding home was a possibility. For many years the lessons were carried on in an ordinary parish room under great difficulties for want of proper accommodation, but, though the school in itself has always been self-supporting, it was not possible

to think that it could produce the home of its own, which the committee felt to be essential to its enlarged opportunities." Also they were of opinion that, if the School was to maintain its position and become a means of permanent education to the village of Keswick, it was impossible either to meet the demands of the public or the requirements of the worker, with the very limited accommodation which their temporary premises afforded. So the had recourse to subscription (being able from the school funds to contribute £200, no mean surplus over working expenses), and in a short time over £1,000 was raised, the result being that a lovely unpretentious building grew up on the banks of the Greta, a memento of the old lake-country style of domestic architecture, with a character and charm of its own.

To see the workers at work, one must, of course, visit the Keswick School of Industrial Art in the evening, but it is well worth seeing the place by daylight, to judge of its beautiful position and adaptability for its requirements. Just outside the town over the Greta Bridge, we come to a neat gateway and garden, and a few yards bring us to the door of the pretty little two-storied building of lake country slate, with its outside winding staircase and picturesque wooden balcony; it looks up to the homes of Southey and Coleridge; underneath the balcony are words which represent, as it were, the keynote of its existence:—

"The loving eye and patient hand
Shall work with joy and bless the land."

The ground-floor of the building is entirely devoted to the different workshops, where at present all is silent, but which, a few hours later, will be alive with the ring of the anvil, the beating of brass, and the more silent chip of the woodcarver's tools, as tendril and leaf grow from solid blocks under deft workmanship. The winding tower staircase was specially designed as a separate entrance for the use of visitors to the showroom, so that the workshops should be safe from invasion, and as it is entered the eye is quite dazzled by the glitter, glisten, and sheen of the metal work, upon which the firelight and the departing sunshine are shedding every imaginable lustre. The motto of this rare showroom (the term is most unsuitable to it) is contained in Browning's words:—

"Oh! Earth, as God has made it, all is beauty!
And knowing this is Love, and love is duty."

Such a mass of magnificent outline and extraordinary beauty of shadow is seldom to be seen from any one point of view, much less from a showroom window! But those who have been instrumental in opening many unseeing eyes to their surroundings, would insist that "Art is the expression of man's delight in the works of God," and that the temple of their art, if one may say so, should always be within sight and reverence of the beauty God has made.

So we pass as a matter of course from the cause—Nature—to the effect of its beauty—Art. The sun goes down, and the lights are lit, and every beautiful tint of metal, variety of design and form glance down upon us from walls and tables. It is not intended here to catalogue the many beautiful things that come from this "Home of Arts" in the mountains, but a few words must be devoted to design, as it is set forth in the exquisite copper screens, the endless bowls, the ever-varying trays, sconces, plaques, and wood carvings, the offertory dishes, and service-book backs, to say nothing of a unique coal-box, covered with the fishes of the coal period.

The aim of the promoters of the school is to bring, as their prospectus states, "the designer and workman into such a relation that they become identified as was the case when the arts were truly living." Every one now entering this school is *obliged* to learn drawing, and the dream of its promoters will not be realized until every article produced can be "the handiwork of one man from beginning to end." But at present design in rural hands could not compete for an instant at metropolitan exhibitions, and the Keswick workers know full well that, in this department especially, they owe their exceptional position in home arts to the great ability and untiring energy of one woman, Mrs. Hardwick Rawnsley. Original designs, and designs, copied from anything that is good in any country, age or style, have been her untiring care; ancient Indian designs with their lovely lotus buds and leaves; ancient Coptic designs, strangely recalling those of the oldest Cumberland wood-carving; embroidery, metal work, are all called into the service of home art, by the endless pains and talents of her, the originator or adapter as the case may be. So far, no rustic genius in design has been produced from the art workshops of Cumberland, and until that is so, the Keswick School of Art can never be called quite self-supporting, as the work of Mrs. Rawnsley in connection with it represents the unpaid services of a designer of the hightest class.

But the January evenings creep on quickly, and before we have had time to do more than glance at the Museum, with its Swiss and Italian specimens and books for art study (a sweet reposeful little room where a man might think out his feeling for beauty), or chat with the excellent secretary in her comfortable business room, the hour for this recreation, which is still work, arrives: the men and boys flock in, some fifty in number, and the school is alive with industry and interest.

It must of course be carefully remembered that these "home arts" are in great part done absolutely *at home* in the cottages and homes of the students, but every night there is a class at the school of some sort, and on Thursday nights all its teaching is in operation.

The first room we enter is that for the brass and copper workers, a long chamber with low tables in centre and tables all round the walls; at the first of these sit several boys, tracing from the linen patterns which are no small evidence of Mrs. Rawnsley's endless labour, about a couple of hundred being always obtainable.

On the wall facing your entrance are the words heading this article:

"The makers are the poets; ply your skill,
Coleridge and Southey watch from yonder hill."

One man is at work on what is known as "cut diaper work"; another is employed in hammering out a magnificent design on copper from the Chiesa di Frari at Ravenna; all are in sober, interested earnest.

We pass on to the wood-carving room, where a teacher is at work showing faults and pointing out virtues, among which, first and foremost in excellence, either in wood or metal, may be roughly enumerated clean tracery and good quality of groundwork, the groundwork to be in relation and proportion to pattern, the excellence of the whole design to be decided by its adaptability to the purpose for which the article in question is intended. Here in the wood-carving room we come across a beginner, who having just learned the use of his tools, naturally the first requisite, is preparing to carve a single leaf out of a little block of wood for practice.

A door is opened and the terrible noise at once announces that we are in a smiths' shop, where a lesson is being given by an amateur. This man, with brisk manner and bright intelligence, is one of the enthusiasts of the place; he has his class well in hand; no softening of correction is bothered over by this local art teacher of the north countrie! "Why doa'n't ye beat it reg'lar all round as a've always toald ye?" is the style of reproof administered, and accepted without a word. A few more teachers such as this man, and these workshop schools might be the property of every village. At one time the pursuit of the silver trout and laying the snare for the wily rabbit (the only form in which love of nature seems naturally to come out in a rustic) occupied all the spare hours of this man, but he has, since his work at the school in the evenings, entirely deserted his former pastime for the less venturesome and more profitable work at the class. Though he earns a certain amount like the others thereby, his *teaching* is a free gift, and his enthusiasm a valuable power among his associates. Here we have the sort of man, as to intelligence at all events, for whom Ruskin wrote his *Fors Clavigera;* of which book our workman expressed his approval with the solid patronage of possession, having won a copy as a prize, "Ay—it's a good book!"

Here the beautiful bowls are shaped upon which afterwards some lovely design is to grow, and here too are made the tools for every branch of work in the school. It is the proudest achievement of Keswick that absolutely all tools used are made at home, and here the ingenuity of the men that does not amount as yet to design is often great in inventing some little turn or twist in shape which they know to be specially adapted to their wants in working. There was a triumphant moment among the workers when the school was applied to by another in Bradford as to where it could get a certain tool which Keswick was known to possess. Needless to say the answer went back with pride "all our tools are home-made."

But a visit to the Home Arts School in Cumberland could not in any sense be considered complete without seeing the "finishing shop," as it is called, for which there is not room in the school at present, and to which a little room across the Greta Bridge has been devoted. The man whose special province this department is gave an interesting account of his branch of the trade, and a very important one it is, for here everything made in the school is at present put together; even articles virtually in one piece must be joined somewhere before thry can become candlesticks and teacaddies. Here, also, them important business of polishing is done, and it seems as if "finishing" was likely to be a difficulty in quite realizing the dream of home arts, for in the past ten years, when so many excellent workers have been found, only two finishers have attained to any perfection. It is difficult to say why, unless it be that the work is not so interesting in character, and requires great exactness in detail. Thus it would be impossible that the workman in this department should not, to a certain extent, know his own value to the school, more especially as it was pointed out to him by an offer from a Birmingham tradesman of work to the amount of £40 a month; but "Noa," says the devoted Cumbrian, "t'schule mun cum fust."

And first, indeed, in the hearts of its workers the school does come. "As surely," says Mr. Rawnsley, "as the country side is kept at its deadly dulness for the labouring man on a winter evening, so surely will the pith and marrow of our English rural life find its way up to the bewildering cities, and lose itself, its simplicity, its freshness, its very life, in the flare and glare of our monster towns." The effort to releave this monotony in dull little country places in the winter evenings has been eminently successful, and the people recognize the benefit, and give it their attention, love and gratitude.

I have thought it unnecessary to quote statistics to any minute degree, but some mention of them is necessary for fear of a merely æsthetic valuation being attached to this movement, therefore it may be noted that the little town of Keswick annually produces and sells some £700 worth of this art-work. Among the workers are men of all trades. Pencil-makers are numerous, as it is the special trade of Keswick, a trade that should be a very flourishing industry did not our Government get all their pencils in Germany, as one of the men indignantly remarked. But labourers, boatmen, gardeners, shepherds, tailors, and many another craft are all here banded together in pursuit of the beautiful and in devotion to their work; and there *is* among them, by reason of their teaching, something of the spirit of the Nuremberg wood-carvers of old, something of the attention to a tendril or a flower, which in its highest degree, gave fame to such a man as Benvenuto Cellini.

But whence has come this true spirit of art, whence has come this awakening sense of beauty? Without doubt a mountain race has it within itself, though deeply hidden away, and practically, one may say, non-existent. The spirit to rouse, the power to carry out, the energy and ability to overcome difficulties are absolute necessities for the awakening of enthusiasm, and it would be indeed a very half-and-half account of this art movement of the Fells if I failed to say, that to this power, in the chief promoters of the Keswick School of Industral Art, Mr. and Mrs. Rawnsley, the whole success of the movement is due.

Any why? Because they were not merely content with small ideals, but because the absolute best in art and the opening of the mind to its glorious treasures was their whole single-minded aim, and this, along with the preception, that to follow after the best in nature, in life, and in work, leads to the highest advancement of man, yea, even "unto the King in all his beauty."—*A. M. Wakefield in Forthnightly.*

NOTES AND COMMENTS

A Municipal Public-house—The municipal public-house which has been opened on the Gothenburg system by the Birmingham Corporation, will be a source of much interest to temperance and other orators. The drink is bought by the Corporation, and retailed by the manager, who receives a salary and has no interest in the amount sold. It it curious to see that a quart of beer is the limit of any one customer's consumption in the morning, but he can consume two quarts at night—so that the Corporation take a liberal view of the working-man requirements. It should be added that the house is not at Birmingham, but in the workingmen's village on the site of the new water-works scheme.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

PLANS of the Hall of Justice, Kearny street, Shea & Shea, Architects.

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street.

SETH BABSON, Pres. W. P. MOORE, Vice-Pres.
OLIVER EVERETT, Sec. JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

OCTAVIUS MORGAN, PRES. A. M. EDELMAN, Vice-Pres.
ARTHUR B. BENTON, Sec'y. AUGUST WACKERBARTH, Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.

GEO. W. DICKIE, Pres. W. G. CURTIS, Vice-Pres.
OTTO VON GELDERN, Sec. EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.

JAS. E. BRITT, Pres. J. L. E. Firman, Sec.

BUILDERS' EXCHANGE, Directors meet first Friday in each month at Mission and New Montgomery.

OSCAR LEWIS, Pres. JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday evening of each month.

ADAM BECK, Pres. M. V. BRADY, Sec.

BOOKS AND PERIODICALS.

LIPPINCOTT'S Magazine for December contains a complete novel called "A Chase for an Heiress"—it is somewhat out of the usual tract for a novel and some of the descriptions of the country around Santo Domingo are very fine; this is a novel that will be read with interest not only on account of the story itself, but because of the description of a part of the West Indies once so famous in History but at the present time almost forgotten. "Shutting out the Sea" contains much information of interest to the engineer as it describes some of the efforts made to prevent the ravages of the ocean waves to engulf our shores. As usual the magazine is full of short articles of interest.

SELF CULTURE, a Magazine of Knowledge, contains for December, 1896, an article on "American Architects and Architecture" extracts of which will be found in another column, it is fully illustrated with engravings of both the early and modern style of construction. This magazine which is certainly a departure from the beaten track of magazine literature cannot fail to be welcomed by a thoughtful class of readers; it is published by the Werner Company Chicago and New York.

THE FORTNIGHTLY REVIEW for December comes to hand, and as usual contains many articles of interest, among the number may be mentioned two that come at the present time as very appropriate "Lessons from the American Election," by Francis H. Hardy—the other "The Working of Arbitration" by H. W. Wilson. It is hard to make a choice where all the articles are so readable.

PROCEEDINGS OF THE PURDUE SOCIETY of Civil Engineering 1896. Purdue University, La Fayette, Ind.

This handsome pamphlet contains a list of the faculty of the Department of Engineering Purdue University as well as a list of the members of the Purdue Society of Civil Engineers. The table of contents show a variety of articles of interest to engineers, and one, "Fireproof as a Specialty," of peculiar interest to architects at the present time when the construction of fireproof buildings is so much discussed as well by architects as the public in general.

No. 5.

BUILDING REGULATIONS.

IN THESE series of articles we have, so far, considered laws and actions relative to putting present conditions into the most sanitary form. In this number we will consider Building Regulations for the purpose chiefly of arranging all prospective work in the most perfect and sanitary manner. We cannot do better than to quote again from the Government Report before us:

"The importance of a comprehensive and uniform plan in laying out the suburbs of cities is by no means fully appreciated. It is forgotten that such districts, more or less remote in our own time, may be the very heart of the city in a succeeding generation. The folly of our fore-fathers is often a subject of facetious, and sometimes irritating, comment. But the folly is not all past, and in this regard we of the present are frequently guilty. While we are occupied in undoing the folly of our fore-fathers, and spending vast sums—in the manner of Boston which during the last twenty-five years, spent $40,000,000—to widen or straighten crooked throughfares, we allow the perpetuation of the same evils in rapidly growing suburbs. How often do individuals or companies, in their so-called improvement of certain sections, lay out the acres at their command in streets running at right angles to those already existing, without reference to any system of thoroughfares. When the owner of the adjoining property makes up his mind to improve his possessions he seeks to get out of them the largest amount of salable land and runs his streets in comformity, with his neighbors', or not, as best suits his convenience or interest. Such arrangements as these, in the second or third generation, are bound to create insanitary property. Subsequently these sections become the' slums, the cost of eradicating which, and of making provisions for proper light, air, and ventilation, is simply enormous.

"German cities have taught us a valuable lesson in the matter of laying out suburbs. Improvement plans are furnished by the municipality, and architects are invited to compete in presenting designs. After it has been decided that a certain district shall be opened up, a jury is appointed to assess damages, terms are made with private owners, and the architect furnishing the most acceptable scheme is awarded the prize. In Berlin an effective check is placed upon too rapid urban development by prohibiting building upon unsewered land. Overcrowding on space is likewise a question of deep importance."

As to overcrowding on space there ought without doubt to be regulations preventing building on an entire lot thus causing back to back houses. In the deep lots in San Francisco we find a rear house built often on the back line of the lot with a yard between the front and rear houses; the owner of abutting lot fronting on the next street, rather than give the first builder the advantage of light from his yard does the same thing and back to back houses are at once formed; this should be disallowed. Air stagnates and an unsanitary state of affairs is at once obtained.

"The results appear in the following table:

ANNUAL DEATH RATE PER 1,000 DURING FIVE YEARS IN BACK-TO-BACK HOUSES IN MANCHESTER ENGLAND.

[From Provisional Report on Back-to-back Houses, by the Medical Office of Health, Manchester, April, 1891.]

Groups	Total population	Precentage of back-to-back houses	All causes
I	8,713	8	27.5
II	11,749	23	29.2
III	11,405	66	30.5
IV	892	100	38.4

"The general sanitary condition of these groups was practically the same; but notwithstanding this the table disclosed the fact that the general mortality in back-to-back houses exceeded that in dwellings of the same class with through ventilation by 40 per cent, the mortality from infectious diseases by 93 per cent, and that from consumption and other lung diseases by 86 and 39 per cent, respectively. The mortality from diarrhea was more than twice as heavy. In every case the death rate from all these classes of diseases increases as the proportion of back-to-back houses increases.

"Overcrowding on space is a very important matter. Liverpool is the most densely populated city in Great Britain. Its death rate is, with one exception, also the highest. Still, density of population as the cause of a high death rate must always be considered in reference to the character of the buildings. Sir Sydney Waterlow testified that the average number of persons housed on an acre of space by his company was 1,000. He was of the opinion that this was not too many where good ventilation was provided and where streets are wide. His theory seems to be borne out in the investigation made by Dr. Arthur Newsholme into the vital statistics of the Peabody and other block dwellings in London which show a most favorable death rate. The exact results of this inquiry are given elsewhere. It is undeniable that block dwellings, when very high, cause drafts of cold air in the streets below and shut off other property from the rays of the sun. *Human beings are said to be as much dependent for their health upon sunlight as are plants.*"

The last sentence leads us to the necessity of abolishing cellars and other underground constructions; or if that may be too radical a change at least have laws preventing the use of them for any purpose whereby people are compeled to be in them for more than a few minutes; there is no excuse for having these places, for there is plenty of unoccupied ground waiting for the occupation thereof by above ground structures without boring in the earth like gophers.

The same argument holds good in regard to tall structures above ground.

Looking at London we find the following provisions for rear open space:

"Frontage of building not exceeding 15 feet, open space at the rear 150 square feet; not exceeding 20 feet, the minimum space at the rear 200 square feet; not exceeding 30 feet, the minimum space at the rear 300 square feet; exceeding 30 feet, the minimum space at the rear 450 square feet. There should be no buildings erected on this space higher than the level of the ceiling of the ground floor story, and the space should extend throughout the entire width of the building. This provision had reference to buildings built after 1882, not to those constructed previously.

The act of 1882 is the one which is still in force in London, notwithstanding the recommendation of the royal commission on the housing of the working classes, in 1885, that in the rear of every new dwelling house, whether in old or new streets, there should be provided a proportionate

extent of space belonging exclusively to it, to be free from erection of buildings thereon from the ground level upward, that the space extend laterally throughout the entire width of the dwelling house, that for the distance across the space from the building to the boundary of adjoining premises a minimum should be prescribed, and that this minimum should be increased with the height of the dwelling house or building.

The London county council, in the case of the Boundary street area in Bethnal Green, among the requirements for buildings to be erected on the land, laid down the following conditions:

1. That blocks of dwellings should not exceed 40 feet in height.

2. That parallel blocks should be separated from each other by an open space, clear from the ground, of at least 40 feet in width.

3. The new streets must be 40 feet in width, and the blocks run almost due north and south, so as to admit the maximum amount of light to all the tenements equally.

4. Courtyards between the blocks are to be left entirely open at each end, and unobstructed by cross buildings.

"Land sold under these conditions can not, of course, bring a very good price; but Dr. Parkes makes the point that it is better that the scheme should cost a great deal to the ratepayers of this generation in order that future generations may not have to pay a further price for the sanitary neglect of the present.

"It may be interesting, therfore, to know, from the accompanying diagram (plan No. 2), the proposed method of regulating open space in the rear of dwelling houses in London.

"The general principle of the plan is that an open space, free from any building, 10 feet in depth throughout the entire width of the building, is left at the rear. The remainder of the ground may be covered with any buildings, provided no part of them, except the chimneys, pass above a line drawn at an angle of 45 degrees from the rear toward the house. This is a most excellent requirement, for it treats houses, whether large or small, in proportion to their size. The plan is also adopted in Liverpool."

Private owners putting up the same character of dwellings are subject to proper sanitary and constructive regulations, to some of which objections are made by owners, we presume principally on account of the buildings not paying sufficient interest when these regulations are adhered to.

"The regulations to which private building companies object are:

1. Staircases must be four feet wide.
2. Dwellings must not be higher than four stories.
3. Ceilings must be 9 feet high.
4. Comparatively severe requirements regarding light and air spaces.

"The council consider, however, that the real reasons for their refusing to build on land owned by the county council are the careful supervision maintained by its clerk of the works in reference to construction and materials used, and also the requirement that men employed must be paid union rates of wages. The latter stipulation, it is said, will enhance the cost so that, considering also the better borrowing powers of the public body, private companies would be at a disadvantage. Both the County Council and the building companies look forward to a compromise.

"Regulations adopted by the London County Council for building houses for working people upon its own land conain the following prescriptions:

"Staircases—A central staircase in blocks of dwellings is objectionable, and as regards convenience of plan and thorough ventilation of each dwelling, the best amongst the modes commonly in use is that which provides a staircase close to the outer wall, and having large openings communicating with the open air. Such a staircase can be conveniently arranged to give access to four dwellings, and the ventilation of such dwellings can be effected by means of open doors and fanlights, so that a thorough current of air can be obtained when it is desired. If it is felt in the winter time that this arrangement leaves the persons using the staircases too much exposed to the weather, windows partially enclosing the openings can be provided.

"The chief alternative to this kind of staircase seems to be one which is in the center of the block, and gives access to dwellings on each side of it. In this case the ingress of fresh air to the staircases can only be through the entrance doorway and along a short passage, and through the skylight at the top of the staircase. Upon this the dwellings opening from the staircase have to depend for their through ventilation.

"Both these plans are in considerable use.

"Staircases in buildings more than three stories high should be at least 4 feet in width. The walls of the staircases to a height of about 4 feet 6 inches should be finished with glazed or hard-pressed bricks; the upper portions with hard bricks neatly pointed.

"Basement floors.—There is no doubt that, as compared with the other floors of a building, the basement floor is undesirable as a residence, but in building artisans' dwellings it is generally expedient to construct a story below the ground floor, though it is not necessary that they be used as dwellings: but inasmuch as there is no definite evidence at the present time that basement rooms, frontiug upon a principal street, should not be used for dwelling purposes, their use need not be forbidden, provided that adequate precautions against fire are taken, and that the bottom of the window sills is not lower than than the level of the adjoining pavement, and not more than 3 feet above the floor, and that in other respects they agree with the provisions of section 103 of the metropolis local management act, as applied to new buildings.

"They are usually let at a rate materially lower than the rooms above them, but if they are let at the same rate as the upper floors in a high block of buildings, they are pre ferred by many people who are not able to mount a considerable number of stairs. Beyond the question of health, it is not necessary to object to such rooms on account of their proximity to the street, those who occupy them being able to make such arrangements for privacy as they find necessary.

"Where no areas are practicable, the walls should be covered with asphalt or other damp-resisting material, from the damp-course to the footings.

"Bathrooms, etc.—Uuless they are in close vicinity to public baths and wash houses (a condition which can very rarely happen), bath and wash house accommodation should be provided to every block of dwellings, and this can best be provided in a separate building or on the basement floor, or in a distinct section of the block that can be constantly

under inspection, and to which inexpensive arrangements for water supply, etc., can be applied.

"In connection with this matter, the water-closet accommodation has been considered, on the assumption that the dwellings to be built or promoted by the council will generally be for the accommodation of the lowest class of the population which inhabits separate tenements, a class just above that which uses the common lodging houses, and for which neither private speculators nor the societies for building artisans' dwellings make any provision. It seems inexpedient that either water-closets or separate water supply or sinks should be constructed so as to be immediately accessible from any dwelling rooms. A sufficient number of closets should be supplied to each floor of dwellings to which a separate staircase is provided, together with a provision of sinks and water supply for common use. Such closets should have both doors and windows opening directly to the open air; and where possible, there should be one closet to each family.

"Dust shoots should be provided from each common scullery, or from the landing adjacent, to discharge into galvanized iron movable dust bins, which can be carried out and emptied into the dust cart.

"Size of rooms—The number of rooms to be provided in each tenement, and their sizes, have been considered as one question, and the following may be regarded as minima:

"1. In a one-roomed tenement the minimum superficial area should be 144 feet. This would conveniently be provided in a room measuring about 12 feet by 12 feet.

"2. A two-roomed tenement should have a similar room, with an additional room containing 96 superficial feet, or measuring 12 feet by 8 feet.

"3. A three-roomed tenement should have a large room containing 144 feet in superficial area, and two rooms each containing 96 feet.

"These sizes, however, should not be rigidly fixed, but rooms of various sizes should be provided. Four-roomed tenements need not be provided, but if they are, the fourth room should be of about 100 feet superficial area.

"It would be convenient as regards planning, and also as regards the population to be accommodated, that some little variety should exist in the sizes of the rooms in each tenement as well as in their number, in order to provide for the different conditions of the families.

"The standard height for every room should be 9 feet. The walls of the rooms should be finished in some hard material, for which purpose Portland cement upon brickwork, or brick with pressed face on both sides, should be used up to a height of about 3 feet 6 inches. The upper parts of the walls can be finished by a thin coating of hard plaster upon brickwork, but upon this point some further inquiry is desirable.

"In designing the buildings, some care shoul be taken to give a pleasant appearance to them.

"As regards the interval which should exist between any block of dwellings and the nearest building obstructing the light from its windows, it is suggested that, if practicable, this distance should be equal to one and one-half times the height of the obstructing building. But it does not appear that this space can, in view of the cost of land, be generally provided. Under no circumstances should a nearer distance than the height of the buildings be allowed."

The regulations regarding basement floors appear to be too lenient. There is no good reason for any living room being on or below the level of the ground where the surface is flat, although on the side of a hill, many examples of which we find in San Francisco, living rooms could be allowed in the part of the basement above the natural grade of the adjoining earth.

The higher standard of living on this coast, which we hope may ever be maintained and raised, makes many of these regulations, those in regard to houses for the very poor, hardly necessary at present here. However, if something is not speedily done we will find that such dwellings will spring up and have to be used, and in that case let them be as good as we can make them.

In our next number we will take a glance through all the principal building regulations of the world—compare the same with the San Francisco Building or Fire Ordinance as a type of the Pacific Coast and see where improvement can be made therein.

SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS.

THE usual monthly meeting of the San Francisco Chapter of the American Institute of Architects was held at their rooms 408 California street on the 11th inst.

The annual election for officers was held and the present incumbents were all re-elected.

The most important matter coming before the meeting was the consideration of the draft of a proposed bill concerning the method of obtaining plans for public works prepared by Mr. Cuthbertson. After some discussion the matter was referred to a committee composed of Messrs. Sanders, Pissis and Hendrickson. An invitation was extended to Mr. W. G. Wright to read a paper before the Chapter on the subject of Quantity Surveying. The meeting then adjourned.

After sundry amendments the committee agreed upon the following as the text of the proposed bill above mentioned:

ACT FOR OBTAINING PLANS FOR PUBLIC WORK.

Section 1. Any State or County officer or officers, or any Board of Supervisors or Municipal Corporation or any Board of Trustees or Commissioners or any person or persons created or appointed by authority of law or any statute, called hereafter in this statute "the authority", are about to erect, or cause to be erected or constructed any State, County, Municipal or other architectural or engineering structure, the total cost of which is estimated to exceed the sum of $20,000 it shall be the duty of said authority to advertise for preliminary plans and specifications for said architectural or engineering structure—and to state in said advertisement the amount authorized by law or otherwise to be expended for the erection of said structure and the prizes which shall be offered therefor. There shall at least be three properly graded prizes offered therefor, the aggregate amount of which shall be one per cent for all plans involving expenditure up to $200,000 and one per cent for the first $200,000 and one-half per cent for all over that amount for structures involving an expenditure over $200,000.

The authority shall employ an expert or experts for consultation and to examine said plans and report to it thereon—said experts shall be competent architects for all architectural structures and competent engineers for all engineering structures.

Sec. 2. Whenever the preliminary plans and specifica-

tions of any architect or engineer shall be adopted, said sketch plan and specification shall become the property of the authority calling for the same upon the payment to the author thereof of the sum of one per cent of the total amount appropriated and to be appropriated to complete the aforesaid structure.

All the other plans and specifications including all premiated ones except the first shall be returned to their presenters immediately after the award. Upon the adoption of said preliminary plans and specifications said authority shall appoint as architect or engineer for an architectural or engineering structure respectively, the author of the adopted design. It shall be the duty of said architect or engineer to prepare full working drawings and specifications and give supervision for a structure to cost no more than the amount mentioned in the advertisement conforming as near as may be to the said preliminary plans and specifications for which he shall be paid the additional sum of four per cent of the total cost of said structure or of so much of said structure as may be carried out at any one time. A superintendent of works shall in all cases be appointed to superintend the construction of said structure whose salary shall be paid by the authority.

Sec. 3. Any action of the authority in violation of any or all of the provisions of this Act shall become null and void.

Sec. 4. The Act of 1872 and all other acts relating to the obtaining of plans for public works by bonds or otherwise are and are hereby repealed—and this act shall go into force as soon as passed.

For the information of our readers and for comparison we publish the present statute on the subject:

Section 1. Where by any statute of this State power is given to any State or County officer or officers, or any Board of Supervisors or Corporation, or any Board of Trustees or Commissioners or other person or persons created or appointed by authority of any such statute to erect, or cause to be erected or constructed any State or County, or other building or structure, it shall be the duty of said officers, Board of Supervisors, Corporation, Board of Trustees, or Commissioners, or other persons, to advertise for plans and specifications in detail for said building or other structure, and to state in said advertisement the amount authorized by law or otherwise to be expended for the erection of said building and also the premium to be awarded to the architect whose plan and specifications for the same may be adopted.

Sec. 2. Whenever the plans and specifications of any architect shall be adopted, such officer or officers, Board of Supervisors, etc., so adopting the same, shall before any premiums shall be awarded for such plans and specifications, require such architect to execute and file with such officers, etc., a good and sufficient bond with two sufficient sureties thereto, in the penal sum of five thousand dollars to be approved by said officers, etc., as the case may be, and conditioned that within sixty days from the date of said bond he will, on presentment to him, enter into a contract containing such provisions and conditions as may be required by such officers, etc., and also conditioned that he will give such further bond to secure the faithful performance of such contract, with such sureties as may be required of him in the event that such officers, etc., so acting under authority of law should, within said sixty days, require said architect, to enter into such contract to erect such building at the price named in said advertisement to be expended for such purpose. In case said architect whose plans and specifications are adopted should enter into such contract, it shall be the duty of such officers, etc., to employ a competent architect or superintendent, to superintend the erection of such building or structure, and to see that such plans and specifications are faithfully carried out.

Sec. 3. All contracts entered into by such officers, etc., in violation of the provisions of this act shall be null and void.

TRANS-MISSISSIPPI AND INTERNATIONAL EXPOSITION, OMAHA, NEBRASKA.

Sealed proposals will be received by the undersigned, until Twelve (12) o'clock noon of Monday, the 11th day of January, 1897, for the services of a thoroughly competent Architect, as Supervising or General Architect for the Trans-Mississippi and International Exposition, which opens June 1st to November 1st, 1898. Total cost of Exposition Buildings estimated $1,000,000.

Proposals must state salary desired, qualifications and experience of applicant, and such references or letters as may be deemed of value by applicant. Engagement to begin immediately upon selection being made, and terminate at pleasure and discretion of Exposition management.

By order of the department, Buildings and Grounds,
John A. Wakefield,
Secretary.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

Agency of Husband for Wife in Building.—In an action for the price of lumber alleged to have been sold to a married woman, and used in improving her estate, the defense was that the lumber was purchased by the husband on his own credit. The sellers testified that the husband stated that the lot on which he wished to use the lumber was owned by himand his wife; that the woman was present when the lumber was delivered, and gave directions where it should be placed, an expressed herself as being glad that it had come. The court held that this was sufficient to establish the fact that the sale was made to the woman.

Holden v. Kutscher, 40 N. Y. Supp. Reporter, 737.

Covenant in Deed Restricting Building Line.—Where a tract of land is laid out in lots and blocks by the owner for sale in accordance with a general scheme, by which restrictions as to building are imposed on each purchaser, for the benefit of all of the land, such restrictions being embodied in all the conveyances, the right of one lot owner to enforce the covenant against another is not a legal, but a purely equitable right, and will only be enforced where it is equitable in that particular case. A court of equity will not require the removal of a building on the ground that it is in volation of a building convenent, where the grantor and owners of the other lots permitted its erection without objection; and subsequent purchasers of adjoining property are bound by the laches of their grantors.

Trout v. Lucas, Ct. Chancery N. J., 35 Atlantic Rep. 153.

Statement Against Architect.—A complaint, under the laws of Massachusetts, alleging that an architect, employed to superintend the erection of a house, had falsely and negligently, and acting in collusion with the builder, represented that a certain amount of labor and materials had gone into the house, whereby the owner was induced to pay the builder an amount of money called for by the contract, is a sufficient allegation of fraud and negligence to show a cause of action against the architect. In giving oral aduice or statements to his employer, the architect is, or may be found to be, rendering a purely partisan service, and if he is then he is bound to show reasonable care and judgment. As a consequence of his contract of employment, the law throws the risk of his statements upon him at an earlier point than it would do otherwise. Aside froN his contract, he would not be liable for statements, unless fraudulent, or for advise, unless dishonest. Under the contract, negligently erronious statemems and imprudent advice become wrongs.

Corey v. Eastman, Sup, Jud. Ct. Mass., 41 N. E. Rep. 218.

BUSINESS MOSAICS.

The Ives Patent Sash Lock—This Sash Lock is now made is cold rolled steel, bronze and brass in all the popular finishes. The acknowledged superiority for the complete manner in which they perform the work they are intended to do is a recommendation for their use, that cannot be disputed. Hobart B. Ives & Co., New Haven, Conn., are the manufacturers.

Drummer—Who was that man whom I overheard denouncing the new Town Hall? Village Merchant—That was the architect who didn't plan it.—*Puck.*

If you want anything in the way of Plaster Decorations or any plastering repaired, go to Samuel Kellett, 28 Ellis street, San Francisco or 375 Twelfth street, Oakland.

Jones—Who was it that said, "The unexpected always happens?" Jenkins—I don't know. Wasn't it somebody connected with the Weather Bureau?—*Puck.*

William Wolff & Co., 327–329 Market street are the agents of the German Alsen's Portland Cement, which they claim is the strongest, finest ground and most uniform cement in the world, having the largest works and greatest production.

Mr. Fussy—I don't see why you wear those ridiculous big sleeves when you have nothing to fill them. Mrs. Fussy—Do you fill your silk hat?—*Boston Standard.*

If those who are about to build extensively will look into the matter thoroughly, they will find that Dixon's Graphite Paint is what they want for tin or iron roofs, and should insist that their architects place this in their specifications as it is a fact that no other paint will make a tin or iron roof last so long. Joseph Dixon Crucible Co., 304 Market street, San Francisco is the place you can find the article.

First Cannibal—She's a peach. Second Cannibal—How fortunate! I'm a vegetarian by preference, you know.—*Detroit Tribune.*

Steven's Patent Chimney, has the endorsement of architects and builders as well as being approved by the Fire Wardens. F. M. Stevens, corner of Larkin and Market streets, also nealer in terra cotta pipe, sewer pipe, chimney tops and flower pots.

Yeast—Is your wife liberal minded? Crimsonbeak—I guess so; she seems to give me a good deal of it.—*Younkers Statesman.*

The early rain will call attention to the importance of having a house that don't leak. To prevent leaks and having your house water-proof go to the Paraffine Paint Co., 116 Battery street, San Francisco. As they deal in felt and composition roofing and building paper as well as Paraffine Paint and know all about their business, that is the place to go if you want a weather proof house.

If you want a perfect jem in the way of a bath tub, call upon Mr. James in the Flood Building, who will take pleasure in showing you his Imperial Porcelain Roll Rim Bath Tub, manufactured by The John L. Mott Iron Works, as Mr. James is the representative of this country on the Pacific Coast, he will be able to give you information about the other improvements in this line that the company is constantly producing; the chances are that you will not leave his place without giving an order for something.

CITY BUILDING NEWS.

Baker near Page. Carpentry work, etc.; owner, Jas. Hawkins; architect, A. C. Lutgens; contractor, Frank Steinman; cost $3650.

Beulah near Cole. To build; owner, Robert Pieper; contractor, Edw. Cox; cost $6900.

Bush near Broderick. Alterations and additions; owner, D. J. Hesselmeyer; architect, J. E. Kraft; contractors, Brennan & Son; signed, Nov. 16; filed, Nov. 28; cost $2788.

California and Front. Elevator for four-story brick; owners, Rosenbaum; Bros.; contractor, W. L. Holman.

Cole near Beulah. Five two-story frame buildings; owner, Charles Hinkle days work; cost $25,000.

Eddy near Devisadero. To build; owner, Miss Mary E. Roberts; architect, H. A. Schulze; contractor, T. R. Bassett; signed, Nov. 25; filed, Dec. 2; cost $1740.

Eleventh near South San Francisco. Two cottages; owner, J. W. Kelly; architects, Townsend & Wyneken; contractor, M. J. Scott; signed, Nov. 13; filed, Nov. 14; cost $2265.

Ellis and Powell. Store fixtures; owners, N. C. and H. C. Wolf; architects, De Prosse & Meussdoffer; contractors, L. & E. Emanuel; signed, Nov. 20; filed, Nov. 21; cost $795.

Ellis and Powell. Plastering, etc.; owner, Royal Eagle Distrillerie Co.; architect, E. Kollofrath, contractor, W. C. Watson; signed, Nov. 19; filed, Nov. 30; cost $2500. Cabinet makers work; contractor, G. Brandlein; cost $1750. Stucco work; contractor, A. Le Jenore; cost $1500. Marble; contractor, J. McCarthy; cost $2100. Interior finish; contractor, S. Levi; $2130.

Francisco near Powell. To build; owner, Antonio Chichizola; contractor, Henry J. Weiss; cost $2050.

Fulton near Steiner. To build, owner, Fannie Mahon; architect, W. H. Lillie; contractors, Moore & Cameron; signed, Nov. 16; filed, Nov. 17; cost $2997.

Fulton near Baker. To build; owner, Mary Horgan; contractor, J. J. Mauseau; signed, Nov. 16; filed, Nov. 17; cost $3740.

Fulton near Baker. To build; owner, Robert McMillan; architect, E. J. Vogel; contractor, D. Currie; signed, Dec. 14; filed, Dec. 18; cost $9100.

Geary near Larkin. Alterations and additions; owner, Esther Attell; architects, Townsend & Wyneken; contractor, John Hayes; signed, Nov. 21; filed, Nov. 21; cost $2260.

Grant Ave. and Sutter. Fixtures for two-story brick; owner, D. Samuels; architect, E. R. Swain; contractors, W. T. Veitch & Bro; cost $3709.

Green and Stockton. To build; owner, Nathan Joseph; architects, Kenitzer & Barth; contractor, Joseph Wyllie; signed, Nov. 28; filed, Nov. 28; cost $1690.

Jackson near Sansome. Carpenter, brick work, etc., on three-story brick, owners, Domingo and Lewis Ghirardelli administrators estate of Dominigo Ghirardelli; architects, Wm. Mooser & Son; contractors, Campbell & Pettus; signed, Nov. 18; filed, Nov, 19; cost $6794.

Larkin near Chestnut. Additions; owner, C. A. Kenniff; contractor, W. W. Rednall; signed, Nov. 17; filed, Nov. 18; cost $885.

Lombard and Baker. To build; owner, John K. Meyer; contractor, Chas. Alsup; cost $2700.

Market between 3d and 4th. Store front interior finish; owner, Claus Spreckels; architects, Reid Bros.; contractors, Thomas Day & Sons; signed, Nov. 10; filed, Nov. 28; cost $4087. Plastering, etc.; contractor, Thomas Mannix; cost $1496. Plumbing, etc.; contractor, S. Ickelheimer; cost $1942. Wire work, etc; contractor, Justinian Caire; cost $1566. Refrigerating plant; contractor, Cyclops Iron Works; cost $3526.

Mission near Fair Ave. To build; owner, Jos. E. Theriot; architects, Mahoney & Ryland; contractor, J. F. Millerick; signed, Nov. 21; filed, Nov. 25; cost $1250.

Missiod near Fourth. Alterations and additions. Owner, N. A. Hewston; architects, Shea & Shea; contractor, Daniel Powers; cost, $3633.

Mission near 8th. Plastering on brick building; owner, Ed. McLaughlin; architect, Chas. Geddes; contractor, Chas. Dunlop; signed, Nov. 18; filed, Dec. 2; cost $1098.

Ninth Ave.. Cottage; owner, Mrs. Eugenie St. Paul; architect, Wm. Curlett; contractor, Wm. Linden; signed, Nov. 4; filed, Nov. 25; cost $1600.

Sacramento near Van Ness. Mason work; owner, J. Z. Posadas; architects, Pissis and Moore; contractors, Peacock & Butcher; signed, Nov. 25; filed, Nov. 27; cost $3650. Carpentry; contractor, Robert Smilie; cost $12,787. Sandstone; contractor, J. D. McGilvray; cost $7500. Plumbing; contractor, S. Ickelheimer & Bros.; cost $2619.

Sacramento near Devisadero. Three-story frame; owners, Geo. H. and Belle W. Holstein; architect, W. H. Lillie; contractor, M. J. Savage; signed, Nov. 30; filed, Dec. 1; cost $5160.

Sanchez near Day. Cottage; owner, W. F. Laumeister; architect, Casper Zwierlein; contractors, Sarcander & Thompson; cost $1400.

Second near Folsom. Two-story frame; owners, W. F. Nicols & W. B. Hooper trustees; architect, Albert Sutton; contractor, Sidney Walker; filed, Dec. 1; cost $5946.

Shrader near Beulah. Five two-story frame dwellings; owner, A. Wilford; day's work; cost $25,000.

Shrader near Beulah. To build; owner, Wm. D. Ladd; architect, E. Depierre; contractor, John Hood; signed, Dec. 14; filed, Dec. 21; cost $2470.

Sutter and Hyde. Six-story brick; owner, Dr. Julius Rosenteirn; architects, Salfield & Kohlberg; contractor, Geo. H. Tay & Co.; cost $2765.

Sutter near Fillmore. Additional story; owner, Merton S. Price; architect, Oliver Everett; contractor, Christ Krutte; signed, Dec. 2; filed, Dec. 2; cost $3412.

Twentieth Ave. near Pt. Lobos. Frame dwelling and stable; owner, Mrs. Marie Forst; architect, J. E. Kraft; cost $3340.

Twenty-fourth near Alabama. To build; owners, Wm. Splain & Sons; architect, M. J. Welsh; contractor, J. T. Coleman; signed, Nov. 21; filed, Nov. 23; cost $2666.

Van Ness and Clay. Ceilings of porticos, etc.; owner, Claus Spreckels; architects, Reid Bros.; contractors, L. & E. Emanuel; signed, Nov. 10; filed, Nov. 28; cost $1898.

Webster near Broadway. Interior finish; owner, W. B. Brown; contractor, W. Bell; cost $12,000.

York near 23d. Two-story frame; owner, F. E. Almquest; architect, J. Peterson; contractors, Miller & Fredrikson; cost $2400.

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

AS 1896 has past nothing more need be said of it here except that amidst the numerous failures and tragedies the CALIFORNIA ARCHITECT AND BUILDING NEWS still stands.

During the year it has advocated various improvements in our social arrangements, which advocation we are glad to see has generally been received with favor; in some cases leading to practical results, in others simply laying the foundation for a public opinion.

The following are some of the subjects which have been ventilated in this paper in its last volume and their present status:

Our endeavors for obtaining a decent law providing for a method of obtaining architectural service for public work will, we hope, be crowned with success in the session of the present Legislature, having received the valuable aid of the San Francisco Chapter of the American Institute of Architects

Our efforts made in conjunction with Regent Reinstein's—again with the valuable assistance of the San Francisco Chapter of the American Institute of Architects—to obtain a plan for a comprehensive arrangement of buildings for the California State University have eventuatd in the offer of Mrs. Hearst to set aside sufficient money for the purpose of getting the result of the labors of the foremost talent of the country in evolving a suitable plan therefor.

We are also glad to note the stand made by our Supervisour against the erection of inordinately tall buildings, inveighed against in our Journal.

Our strenuous efforts to obtain a Post-Office for San Francisco has not resulted in any thing further than a statement that the working drawings are about finished—that is something however.

Another of our proteges, the Torren's system of transferring title to real estate will be brought up in this Legislature—result uncertain.

Our opposition to the proposed new Charter for San Francisco has fortunately been justified by the vote of the people and we feel encouraged to hope that another attempt will be carried out more on the lines outlined in our April number.

The last Grand Jury has urged the necessity of Fire Escapes on our School Houses and other public buildings, and we hope practical effect will be given to their recommendations before long. This is another of our fads.

We are also glad that ordinances have been passed in San Francisco and other chief cities of the State for the purpose of putting a stop to the criminal act of placing any articles on the sidewalk as may cause damage to life or limb, and to health, a result of the movemeni inauguated *by us in our last volume*.

So altogether we may feel encouraged and will keep on in 1897 pointing out what we think wrong and what we think right.

Our series of articles on the Housing of people of small incomes will be continued during this year—forming valuable contributions to Urban Science and worthy the serious attention of all public bodies, and we intend to keep up the present standard of the journal, if not to improve thereon, which latter we shall certainly do if encouragement enough is given.

CONSIDERABLE agitation is now going on in regard to the proper position of a Pest House or Hospital for contagious diseases, the presence of which in our midst is unfortunately a necessity from our present imperfect knowledge and carrying out of the Laws of Hygiene.

Without doubt a position in the centre of a town and particularly when placed in the way of the prevailing winds, blowing over it into the most inhabited part of the City and causing the sewerage therefrom to pass through the same before it can be got rid of is bad. When said city is placed on a peninsula like San Francisco the problem is easy to solve; place the Pest House near the edge of the water on the lee side and in a place where residences are likely to be few. A place like the top of Telegraph Hill seems to answer all purposes, its height allows any germs in the air to be blown into the bay—it can be drained directly into the intercepting sewer—and no habitations are close or likely to be close. To get there an elevator can be built on the steep side, or a cable car run as there used to be. We hope that the citizens will insist upon such a locality as the one mentioned being chosen.

IN re-introducing into the New York legislature what is called the Pavey Bill for regulating the heights of buildings in New York city, a curious oversight has been made.

The Bill provides that no building shall be erected of greater height above the curb level than fifteen times the square root of the width of the street, but neglects to say what denomination that width shall be taken in; whether feet, inches, yards, or miles, and it makes quite a difference in the height of a building, according to what denomination is taken, *e.g.*, if feet is meant, then for a street one hundred feet wide we have the square root of one hundred which is ten, multiplied by fifteen which makes the height allowed one hundred and fifty feet. If we take the dimension in yards, we have the square root of thirty-three which is 5.745 which multiplied fifteen times equals eighty-six yards or 258 feet.

So if we take the width in decimals of a mile we obtain by the same calculation a pigmy building.

Although the ordinary public would consider that feet are meant, there is no telling what the lawyers and judges would hold if the matter was brought into Court by someone wishing to erect a building higher than implied in the Act, for the ways of such are like the ways of Providence, past finding out.

TO PROTECT WORKMEN.

NEW YORK'S NEW HUMANE BUILDING BUILDING LAW.

SOME curiosity has been expressed as to the exact wording of the building law enacted by the New York Legislature last June relating to the protection of lives and limbs of workmen on buildings in course of erection. The law follows:

SECTION 1. It shall be the duty of all contractors and owners when constructing buildings in any of the cities in the State of New York, where the plans and specifications require the floors to be arched, between the beams thereof, or where the said floors or filling in between floors shall be of fireproof or brick work, to complete the said flooring or filling in as the building progresses to not less than within three tiers of beams below that on which the iron work is being erected.

SEC. 2. It shall be the duty of all contractors for the carpenter work of buildings, in the course of construction, in any of the cities of the State of New York, where the plans and specifications do not require the filling in between the beams of floors to be be of brick or fireproof work, to lay the under flooring thereof as the building progresses on each story to not less than within two stories below the one to which the said building has been erected. Where double floors are not used, the contractor shall be required to keep planked over the floor two stories below the one on which the work is being carried on.

SEC. 3. It shall be the duty of all contractors for iron or steel work of buildings in the course of construction or the owners thereof, in cases where the floor beams are of iron or steel, to thoroughly plank over the entire tier of iron or steel beams on which the structural iron or steel work is being erected, except such spaces as may be reasonably required for proper construction of said iron or steel work, and for the raising or lowering of materials used or to be used in the construction of the said building, or such places as may be designated by the plans and specifications for stairways and elevator shafts.

SEC. 4. The chief officer, in any city, charged with the enforcement of the building laws of such city, is hereby charged with enforcing the provisions of this act.

SEC. 5. Any violation of the provisions of this act shall be a misdemeanor and on conviction shall be punishable by a fine, for each violation thereof, of not less than $25 nor more than $200.

SEC. 6. This act shall take effect immediately.

—*National Real Estate Guide.*

FROM THE THIRD BIENNIAL REPORT OF STATE MINERALOGIST—STRUCTURAL MATERIAL.

BASALT

NAPA COUNTY

Columnar Basalt occurs in Clark's Canon, 12 miles W. of Napa, on the land of Charles Clark, of Napa.

Columnar Porphyry is found on the eastern slop of Mount Helena, 6 miles W. of Kellogg. Columns, 3″ to 5″ diameter, are found, 4′ to 6′ long. The rock is hard and brittle and of a gray color, and stained.

CEMENT

SAN BERNARDINO COUNTY

California Portland Cement Works—See our XIIth Report, p. 380. These are ¼ mile W. of Colton, at 1,000′ elevation. The limestone used in the manufacture of the cement is quarried from a hill situated immediately back of the works. The quarry is connected with the manufacturing plant by an inclined tramway about 1,000′ long, and rising 600′ to near the summit of the hill. The plant, consisting of four Griffin mills, two revolving oil-burning furnaces of the Duree type, and all the other necessary pulverizing and conveying machinery, etc., is located at the side of the Southern Pacific R. R. The limestone, said to be almost pure, is mixed with a certain proportion of clay and fluor-spar from the Castle Dome mines in Arizona, pulverized and roasted at an intense heat. A semi-clay-like mass, or "clinker," is the result. This is cooled and re-ground, and sacked for shipment. A very complete laboratory and testing-room is connected with the establishment. Seventy-five men are employed. The capacity of the works is said to be 200 bbls. per day. California Portland Cement Co., of Los Angeles, owner; F. N. Spear, of Colton, superintendent.

SOLANO COUNTY

Benicia Works—See our XIIth Report, p. 380. Idle. J. G. Johnson and James Clyne, of Benicia, owners.

CLAY, BRICKS, POTTERY, ETC.

ALAMEDA COUNTY

California Pottery and Terra Cotta Co.—See our XIIth Report, p. 381. Its works are on Twelfth street, in East Oakland. There are two kilns, 18′ and 16′ in diameter, fired with wood. Sewer and chimney pipe, flower-pots, vases, tiles, fire-bricks, stove linings, etc., are manufactured. The clay used is obtained from Carbondale, Amador County. Eleven men are employed in the works. S. W. Winsor, of Oakland, manager.

N. Clark & Sons' Pottery.—See our XIIth Roport, p. 381. It is in the City of Alameda, and consists of eleven kilns—two 25′ in diameter, eight 20′, and one still smaller. A Whitacre machine for making pressed bricks is being erected. The company manufacture vast quantities of vitrified sewer and water pipe, chimney pipe and tops, fireproofing, etc. The clays are principally obtained from Carbondale, Amador County. N. Clark, President; George A. Clark, of No. 13 Spear street San Francisco, secretary.

Oakland Art Pottery.—It is on Twelfth street, between Twenty-second and Twenty-third avenues, Oakland. There are three kilns—one 20′ and two 18′ in diameter. All sorts of ornamental vases, flour-pots, chimney pipes and tops, standard sewer-pipe, ornamental tiling, water-coolers, and general terra cotta wares are manufactured. The clays used are principally obtained near Carbondale, Amador County. Twenty-nine men are employed. James Miller, of No. 1125 E. Twelfth street, Oakland, proprietor.

Remillard Brick Co.'s Works.—See our XIIth Report, p. 381. They are on the S. P. R. R., 1½ miles N. E. of Pleasanton. There are two sixteen-compartment Hoffman kilns of 20,000 daily capacity each. But one kiln is now in operation. Only common bricks are made. They are made from a superficial deposit of sandy loam, 25′ thich, which is near the kilns. Sixty men are employed during summer. P. H. Lamoureux, of Oakland, secretary; E. R. Sinard, of Pleasanton, superintendent.

AMADOR COUNTY

In the vicinity of Carbondale are large and numerous deposits of clay of superior quality, and also of sand. In these deposits large excavations have been made at many points and the material shipped to potteries and pressed-brick works throughout the State, large quantities going to Alameda, San Jose, Scramento and even as far as Los Angeles. The total annual shipment of clay alone from Carbondale is about 16,000 tons. Sand, up to the present time, has been shipped in limited quantities to iron foundries, where it is used in molding. This branch of the industry will doubtless grow into greater proportions as the peculiar fitness of this sand for the purpose becomes better known.

Carbondale Pottery—These works are at May P. O., 1 mile from Carbondale Station. There is but one furnace, and this is fired intermittently. Drain-pipe, terra-cotta chimney tops and pipes, fire-bricks, and a line of stoneware, jugs, jars, etc., are the principal articles manufactured here. Fred Hammer, of May P. O., owner.

N. Clark & Sons' Clay-pits.—These are scattered within a radius of 3 miles of Carbondale Station. They are worked constantly, except during the rainy season. To provide the necessary supply during the winter months, several thousand tons are mined and placed under cover during summer. N. Clark & Sons, of Alameda, owners.

Heath & Smith's Clay-pits.—They are in the vicinity of Carbondale, and supply large quantities of clay, of which there are several qualities, to potteries and terra cotta works throughout the State. During the summer months 4,000 tons will be housed for shipment during winter, when the rains make it impossible to dig or ship the clay from the pits. Heath & Smith, of May P. O., owners.

BUTTE COUNTY

Walker's, W. A. Brickyards.—They are 3 miles S. E. of Chico, and supply the local markets at Biggs and Gridley. A superficial deposit of sandy loam, 3′ to 6′ thick, lying between the surface soil and underlying sand, is used successfully. Where hardpan occurs beneath the loam, as in the case in many places, it is said to contain too little sand to make good bricks.

CONTRA COSTA COUNTY

Mount Diablo Pottery and Paving Brick Co.'s Works.—They have been recently established on the railway, ½ mile W. of Antioch. The company will manufacture paving and pressed bricks, terra cotta, fire-proofing, sewer-pipe, flower-pots, roofing-tiles, etc. The clays used are from stratified beds in the foothill, S. and W. of the pottery, and, so far as they have been tested, are said to be satisfactory. E. T. Maple, of Antioch, superintendent.

KERN COUNTY

The Bakersfield Palent Brick Co. of Bakersfield made abont 600,000 bricks during 1895.

LOS ANGELES COUNTY

The manufacture of bricks and terra-cotta ware has been greatly stimulated by the use of oil as fuel, and by the increased demand for structural material. The Pliocene formations around Los Angeles afford an inexhaustible supply of clay suitable for brick, and for mixing with other clays in the manufacture of terra-cotta ware.

Berg & Layne's Brickyard.—It is at Los Angeles. An open kiln, fired by wood, is used, with a capacity of 8,000 bricks a day. Output for 1895, 1,500,000 bricks. Ten men

are employed. Berg & Loyne, of No. 125 W. Second street, owners.

California Sewer-Pipe Co.'s Brickyard.—It is at Vernon, 1 mile S. of Los Angeles. There are three down-draught kilns—one of 20′ and two of 28′ diameter—in which oil for fuel is used. Sewer-pipe, water-pipe, flue-lining, fire-bricks, drain-tiles, etc., are manufactured. The clay is obtained from near Elsinore, Riverside County. Twenty-six men are employed. California Sewer-Pipe Co., owner; T. M. Riley, of No. 649 S. Broadway, manager.

Capitol Steam Brick Works.—Located at Los Angeles. An open kiln, fired by wood, coal and oil, is used. Its capacity is 40,000 bricks a day. Forty men are employed. E. Simons, of No. 125 W. Second street, owner.

City Brick Co.—See our XIIth Report, p. 381. Its yard is located in Los Angeles, and employs an open kiln, fired with wood. Its capaciey is 38,000 bricks a day. Thirty-five men are employed. A. A. Hubberd, of No. 125 W. Second street, manager.

Davin's Brickyard.—It is in Los Angeles, and uses an open kiln, fired with wood. Its capacity is 12,000 bricks a day. Twelve men are employed. P. Davin, corner Saratoga and Brooklyn streets, Boyle Heights, owner.

Eureka Brick Co.—Its open kiln is located at Los Angeles and heated with oil. Its capacity is 18,000 bricks a day. Fifteen men are employed. W. R. Gleason, of No. 127 W. Second street, superintendent.

To be continued.

HARD-EARNED WAGES.

An old chuch in Belgium decided to repair its properties, and employed an artist to touch up a large painting. Upon presenting his bill, the committee in charge refused payment unless the details were specified, whereupon he presented the items as followers:

For correcting the Ten Commandments	$ 5.12
Embellishing Pontius Pilate and putting new ribbons on his bonnet	3.02
Putting new tail on the rooster of St. Peter and mending his comb	2.20
Replumbing and gilding left wing of guardian angel	5 18
Washing the servant of the high Priest and putting carmine on his cheeks	5.02
Renewing Heaven, adjusting the stars and cleaning up the moon	7.14
Touching up purgatory and restoring lost souls	3.06
Brightning up the flames of hell, putting new tail on the devil, mending his left hoof, and doing several odd jobs for the damned	7.17
Rebordering the robes of Herod and adjusting his wig	4.00
Taking the spots off the son of Tobias	1.30
Cleaning Baalam's ass and putting one shoe on him	1.70
Putting earrings in Sarah's ears	1.71
Putting a new stone in David's sling, enlarging the head of Goliath, and extending Saul's legs	6.13
Decorating Noah's Ark and putting a new head on Shem	4.31
Mending the shirt of the Prodigal son and cleaning his ear	3.39
	$60.45

PRISON BARS TO BE WATER PIPES.

ARCHITECT SHEA HAS A NOVEL PLAN FOR THE HALL OF JUSTICE.

Frank T. Shea, the architect of the Hall of Justice, the corner-stone of which was laid on Saturday, will submit to the Board of Supervisors a device for a City Prison to be continued in the building that in point of novelty and usefulness will outrank anything of the kind in the United States. If Mr. Shea's plan be adopted the escape of prisoners will be rendered impossible in the future.

He proposes to construct the cells in the prison of steel pipes, to be filled with water at a high pressure. At the desk of the sergeant in charge of the prison will be a gauge similar to a steam gauge on a boiler, by which the exact pressure of the water will be registered. If a prisoner should attempt to cut his way out of the prison by filling one of the steel bars a stream of water would escape as soon as he filed through the pipe. Simulaneously with the escape of the water an electric bell on the gauge at the sergeant's desk would ring and the indicator would show the number of the cell where the prisoner was trying to escape.

So far as Mr. Shea knows, a device similar to the one proposed by him has never been used in a prison in the United States or elsewhere. He believes that if the plan were given apractical trial, jail deliveries in this city would never be heard of again.

Mr. Shea has also prepared a system of electrical devices that will remove the necessity of having "trusties" in the prison. By pressing a button at his dest the sergeant will be able to open the door of any cell in the prison. The prisoner desired may then step out into the corridor, after which the sergeant may press another button and close the door. The door separating the corridor from the sergeant's office may afterward be opened in the same manner and the prisoner allowed to walk to the desk.

The value of the device lies in the fact that "trusties" are always a source of more or less annoyance in every prison. In many instances jail deliveries have been traced to men who were given the liberty of the prison in order that they might do odd chores about the place.

Whether or not the plans of the Hall of Justice can be changed at this late day to permit of a trial of the devices suggested by Mr. Shea is a question. Mayor Sutro contends the law specifically prohibits the changing of plans for a public building after they shall have been once agreed upon. By others it is contended that the Board of Supervisors has power to authorize a change in the plans where the public good is at stake. The alterations suggested by Architect Shea would not involve the expenditure of any more money for the building, inasmuch as the increased cost of the prison could be saved somewhat else. At any rate Mr. Shea will suggest to the Board of Supervisors the modifications he has in mind with regard to the prison and it is believed that the plans will be adopted.

Mr. Shea wrote into the Patent Office to ascertain if application had ever been made for a patent on a prison cell constructed of steel pipes filled with water, and was informed that no application of the kind had ever been made. He will apply for a patent on the invention.—*Examiner.*

CALIFORNIA ROADS.

The California Bureau of Highways has given to the Governor a report of its labors. It closes with this recommendation:

The adoption of the plan proposed, and the inauguration of the system recommended, together with the minor recommendations, would make the Golden State the ideal highway community of the world.

Let the good work go on. The Legislature is about to convene. A great opportunity lies before it, for it has the united support of the people and of the press, and there is no subject now committed to our law-makers from which California can hope for so much immediate advantage and lasting good as from wise laws now enacted which will result in the construction of a complete system of well built highways throughout the State. The movement has gained an impetus which needs but to be wisely directed to accomplish this.

And in the years to come, when the results of their efforts shall be fully seen and appreciated, it will be found that those who are now giving their time and their energies to this movement for good roads, which is extending throughout the entire nation, will have "builded better than they knew."

CALIFORNIA HAS MORE TO GAIN THAN ANY OTHER STATE FROM GOOD ROADS.

In the marvelous diversity of her products, and the mildness of her climate, California has more to offer as an inducement to rural settlement than any other State, and hence she has more to gain from good roads. For good roads bring in their wake everything which will attract industrious men from the occupations of the cities and from other States and other countries to go out upon the lands of California and till them and build up homes upon them. And in settlement of fertile, but now largely unoccupied lands, must we look for the future growth and permanent prosperity of the State. And wherever such men can gather as they will, in thickly settled rural communities, with easy means of access to near-by towns and interior cities, the problem of labor for manufacturing will be solved. And in its solution, and in the upbuilding of local manufacturing industries to supply the home markets thus created by a thickly settled rural population, lies the true key to the solution of many of the problems of transportation and distribution which are perplexing the California producer of to-day.

Good roads will stimulate the subdivision of large holdings, will give increased value to small farms, thus made more easily accessible to neighbors, towns and market, will promote rural settlement by making life in the country more attractive than city life to the most intelligent classes, and will enable our rural people to maintain the very highest standards of mental and educational acquirement and social life. For rural life in California, even to him who has only a cottage home in the midst of a small farm well tilled, affords the fullest scope for all the refinements of life, and can furnish more daily comforts, and be set amidst more beautiful surrounds, than the most lavish expenditure of wealth can give in countries less favored by nature.—*California Advocate.*

WIRE BUILDINGS FOR TELEPHONES.

BY HERBERT LAWS WEBB.

Every large office building that is put up to-day should be fully wired for telephone service. Telephone communication is almost as much of a business necessity to-day as ink and paper and no modern building can be quite modern, and thoroughly up to date, in which provision is not made for supplying telephone communication to every room. At present, it is true, it is rather the exception to find an office building properly wired throughout for telephone connections, but in a few years the exceptions will be those that are not so wired. The demand for telephone service of all kinds is increasing so rapidly that owners of buildings cannot afford to expose their tenants to the delays and inconveniences incident to running wires through large buildings every time a new telephone service is required. A well designed substantial system of telephone wiring is therefore a necessity in the modern office building, in the modern hotel, in the modern factory and even in the modern club or large residence. The architect who would keep abreast with the requirements of the day cannot afford to neglect this.

There are three requisites that a system of interior wiring should fulfill. These are: 1, that the wires should be suitable for telephone working; 2, that they should be accessible to allow of additions, withdrawals or repairs; 3, that they should all terminate at one central point.

The requirements of clause 1 are not difficult to meet. They demand that every circuit shall be metallic and that the two sides of the circuit shall be twisted together with not less than four twists to the foot. This arrangement of the circuit tends to neutralize the disturbing effects of currents that may be circulating in neighboring wires. As to he size of wire, No. 10 B. & S., insulated to 3-32ds with a good quality of water proof compound is sufficiently substantial. But let it be a good quality; beware of cheap insulated wire, for it is the dearest in the end. It is a good plan to have the two wires of the twisted pair of different colors so that they may be readily distinguished at the ends without the delay of testing out.

Clause 2 means, of course, that the wires should be run in conduits or tubing. The area of inflexible and inaccessible systems of wiring has passed. Every kind of wiring that is done on a large scale should be arranged so that the wires can readily be got at for inspection or repairs, readily withdrawn or added to without disturbing walls, partitions or flooring. Such accessibility and flexibility can only be secured by the use of conduit tubing.

The concentration of all the different circuits at one point is a sufficiently obvious necessity to need no elaboration. The wires should all be taken to a terminal or cross-connecting board by means of which connection may readily be made with the trunk lines from the telephone exchange. The cross-connecting board will also serve to connect together circuits from different rooms in the event of permanent communication being required between officers in the same building.

A complete system of telephone wiring laid out in accordance with the general requisites outlined above is a very important and valuable adjunct to the modern office building.—*Architects' Electrical Bulletin.*

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street.

Seth Babson, Pres. W. P. Moore, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Octavius Morgan, Pres. A. M. Edelman, Vice-Pres.
Arthur B. Benton, Sec't. August Wackerbarth, Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

Geo. W. Dickie, Pres. W. G. Curtis, Vice-Pres.
Otto Von Geldern, Sec. Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

Oscar Lewis, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday even ing of each month.

Adam Beck, Pres. M. V. Brady, Sec.

BOOKS AND PERIODICALS.

LIPPINCOTT'S Magazine for January, 1897, contains among other interesting articles a capital story called "Stockings Full of Money." This is a well written novel, and very cleverly contrives to keep the reader wondering how it ends and who is guilty.

Among our exchanges THE BUILDER, published in Boston at 85 Water street, is always most welcome, as this this journal devoted to the interests of architecture in materials of clay is sure to contain something of use to architects, illustrated in a manner that does credit to the publishers. The prospectus of this journal for 1897 announces the leading articles for the year, as well as the writers who will contribute during the year.

SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS.

THE REGULAR monthly meeting of the Chapter was was held on January 8, 1897.

The principal business was the discussion of a bill to regulate the practice of architecture in the State of California. Mr. B. E. Henriksen was appointed a committee of one with power to act, to present a bill on similar lines to the one defeated two years ago.

The following is the text of the bill introduced into the Legislature by Mr. Pendleton on January 16, 1895 and amended in Assembly, under special instructions, March 2, 1895 and further amended in Assembly February 2, 1895:

AN ACT TO REGULATE THE PRACTICE OF ARCHITECTURE.

THE PEOPLE OF THE STATE OF CALIFORNIA, REPRESEFTED IN SENATE AND ASSEMBLY, DO ENACT AS FOLLOWS:

Section 1. Within sixty day from and after the passage of this Act, the Governor of the State shall appoint ten persons, which persons so appointed shall constitute a Board, which Board shall be known and designated as the State Board of Architecture.

Five members of said Board of Architecture shall be residents of the Northern United States Judicial District of California, and shall constitute the Northern District Board for the examination of applicants for license to practice architecture in this State. And five members of said Board shall be appointed from the Southern United States Judicial District of California, and shall constitute the Southern District Board for the examination of applicants for license to practice architecture in this State.

The districts shall be the same as the Northern and

VOL. XVIII. No. I. JANUARY 1897.

Southern United States Judicial Districts of this State at the time of the passage of this Act.

Said State Board of Architecture shall be appointed by the Governor, as follows: Three members shall be appointed from the members in good standing of the San Francisco Chapter of the American Institute of Architects, (or some similar institute or association of architects), two of whom shall be designated to hold office for two years. Three members shall be appointed from the members of the Southern California Chapter of the American Institute of Architects, (or some similar institute or association of architects), two of whom shall de designated to hold office for two years. One member shall be appointed from the faculty of the Berkeley University, one member shall be appointed from the teachers of the State Normal School at Los Angeles, and two members, one of whom shall be a resident of the northern district and one a resident of the southern district, who shall be lawyers in good standing, and who shall have been in practice for not less than five years.

Each person so appointed shall hold office for four years, unless so designated to hold office for two years. And thereafter, upon the expiration of the term of office of the persons so appointed, the Governor of the State shall appoint a successor or successors to such outgoing person or persons whose term of office shall have expired, to hold office for four years; *provided*, that the membership of the State Boards of Architecture shall be composed as herein set forth.

Each member shall hold over after the expiration of his term of office until his successor shall have been duly appointed and qualified.

Any vacancy occurring in the membership of the Board shall be filled by the Governor of the State for the unexpired term, in like manner.

The members of the Board shall serve without compensation from the State.

The expenses of said Board shall be paid out of the fees collected from applicants for licenses.

SEC. 2. The members of the State Board of Architecture shall, before entering upon the discharge of the duties of their office, take and file with the Secretary of State the constitutional oath of office.

The said State Board of Architecture shall, within thirty days from and after their appointment, meet and elect from their number a President and a Vice-President, one of whom shall be a resident of the northern district, and one a resident of the southern district, and two Secretaries, one from each district. The Secretaries shall also act as Treasurers. The person receiving the highest number of votes shall be Secretary, and the person receiving the next highest number of votes (shall be) Assistant Secretary. Said person shall hold office for two years, or until their successors shall have been duly elected and qualified.

SEC. 3. The Board may adopt rules and regulations for the government of its proceedings not inconsistent with this Act.

The State Board shall adopt a seal for its own use, and one for each of the District Boards. The seal used by the Northern District Board shall nave the words "Northern District" inscribed thereon, and the one for the southern district shall have the words "Southern District" inscribed thereon, and the Secretary and Assistant Secretary shall have charge, care and custody thereof.

The Secretary shall keep a correct record of all the proceedings of the Board, which shall be open to public examination at all times. Six members shall constitute a quorum for the transaction of the business of the State Board of Architecture, and three members shall constitute a quorum for the District Boards for the transaction of business.

Special meetings of the State Board of Architecture shall be called by the Secretary upon the written request of four of its members, and by giving twenty days' written notice of such meeting, and the time and place at which such meeting is to be held, to each member of the Board.

The District Board shall call special meetings upon the written request of two of its members made to the Secretary, and upon five days' written notice to each member of such District Board.

Within thirty days from and after the date of their appointment, the State Board shall meet to organize, elect officers as in this Act provided for, and formulate and adopt a code of rules and regulations for its government in the examination of applicants for license to practice architecture in this State, and such other rules and regulations as may be necessary and proper, not inconsistent with this Act.

The Board may from time to time repeal or modify its rules and regulations, not inconsistent with this Act.

The State Board shall meet annually, on the second Tuesday in April, for the purpose of transacting such business as may lawfully come before it, not inconsistent with this Act.

The District Boards shall hold their regular meetings for the examination of applicants for license to practice architecture, on the last Tuesday of January, April, July and October of each year.

The Board of the Northern District shall meet in San Francisco, and the Board of the Southern District shall meet in Los Angeles, and at such other times and places as they may elect, to examine applicants for licenses.

Any person shall be entitled to an examination for a license to practice architecture upon a payment to the District Board, when he make application, a fee of fifteen dollars which fee shall be retained by the Board; should the applicant pass a satisfactory examination by said District Board, the Secretary shall, upon the payment to him of further fee of five dollars, issue to the applicant a certificate, signed by the President and Secretary, sealed with the seal of the District Board, and directed to the Secretary of State, setting forth the fact that the person therein named has passed a satisfactory examination, and that such person is entitled to a license to practice architecture in this State, in accordance with the provisions of this Act; and upon the payment to the Secretary of State of a fee of five dollars, the Secretary shall at once issue to the person therein named a license to practice architecture in this State, in accordance with the provisions of this Act, which license shall contain the full name of the applicant, his birthplace and age, together with the name of the District Board issuing the certificate, and the date of issuance thereof.

All papers received by the Secretary of State on application for license, shall be kept on file in his office, and a proper index and record thereof shall be kept by him.

SEC. 4. Any architect in good standing, who shall show to the satisfaction of the District Board of the district in which such architect may reside, that he was engaged exclusively in the practice of the profession of architecture on the date of the passage of this Act, shall be granted a certificate without passing an examination, on the payment to

the District Board of a fee of five dollars; *provided*, such application shall be made within six months from and after the passage of this Act.

Said certificate shall set forth the fact that the person to whom the same was issued was practicing architecture in this State at the time of the passage of this Act, and that the person therein named is entitled to a license to practice architecture without having passed an examination by the District Board; and the Secretary of the State shall, upon the payment to him of a fee of five dollars, issue to the person named therein a license to practice architecture in this State, in accordance with the provisions of this Act.

Each licensed architect shall have his license recorded in the office of the County Recorder in each and every county in this State in which the holder thereof shall practice, and he shall pay to the Recorder the same fee as is charged for the recording of deeds. A failure to have his (license) so recorded shall be deemed sufficient cause for revocation of such license.

SEC. 5. Six months after the passage of this Act, it shall be unlawful, and it shall be a misdemeanor, punishable by fine of not less than fifty dollars, nor more than five hundred dollars, for any person to practice architecture without a license in this State, or to advertise, or put out any sign or card, or other device which might indicate to the public that he was an architect; *provided*, that nothing in this Act shall prevent any person from making plans for his own buildings, nor furnishing plans or other data for buildings for other persons; (*provided*, that nothing in this Act shall prevent the recovery of any fee or compensation by an architect residing out of the State of California, whose plans and specifications shall be accepted for a building or other structure within this State.)

Architects' licenses issued in accordance with the provisions of this Act shall remain in full force until revoked for cause, as hereinafter provided for in this Act.

A license may be revoked for dishonest practices, or for gross incompetency in the practice of the profession, which questions shall be determined by the District Board of the district in which the person whose license is called in question shall reside or shall be doing business; and upon a full investigation of the charges by the District Board, an opportunity having been given the accused to be heard in his own defense or by counsel, and upon the verdict of at least four members of the District Board, the Board may issue its certificate to the Secretary of State revoking the license of the person accused; and the Secretary of State shall thereupon cancel such license. And on the cancellation of such license it shall be the duty of the Secretary of the District Board to give notice of such cancellation to the County Recorded of each county in this State, whereupon the Recorder shall mark the license recorded in his office "Canceled." After the expiration of six months, the person whose license was revoked may have a new license issued to him by the Secretary of State, upon the certificate of the District Board by which the license was revoked.

Every licensed architect shall have a seal, the impression of which must contain the name of the architect, his place of business, and the words "licensed architect," with which he may stamp all plans and papers prepared by him.

This Act shall take effect from and after its passage.

THE PREVENTION OF PREMATURE BURIAL.

PSYCHICAL Science has proven that the spirit may leave the body for a while, may seek to return to it, and sometimes succeed in its endeavors. This being the case it is our duty to take such care of a vacant body that if the spirit which occupied it makes an effort to return, it shall find it figuratively swept and garnered, that is, shall not find it in a box six feet below the level of the ground or in any other horrible place. Either this should be done, or the body so destroyed that the spirit will find it imposible to occupy it again.

In plain words arrangements should be made in view of the many cases of premature burial to have a building in every community erected for the special purpose of receiving and holding bodies until they show decided absence of any spiritual presence by their decay, after which any disposition may be made of them that their relatives may see fit.

This building should consist of a large room or hall, situated preferably in one of the cemeteries, built by the municipality, in which the coffins of dead people should be placed and numbered. The top of the caskets should be thin glass so that when decomposition sets in it may be seen, and so that, in the event of any of the bodies being revivified, they might see the glorious light once more and feel safe. The building to have a skylight or other good light and at night to be thoroughly lighted with electricity.

The cushions on which the bodies rest to be connected by electric wires to bells with an annunciator so that at any movement of a body, the attendant, one of whom would be constantly on the watch, would be immediately notified thereof.

If the newly returned spirit should have sense enough to see where it is, by a slight rap it could break the thin glass and thus get fresh air to breath.

Those persons who expressed such a desire could have their body made unsuitable for further occupation by an authorized physician—and thus obviate the necessity of having their bodies laid up in the above reception hall and prevent overcrowding the same. STROLLER.

NOTES & COMMENTS.

RECOMMENDATION MADE BY GRAND JURY IN REGARD TO ARCHITECTURAL MATTERS:—Concerning the public schools of San Francisco the report says:

"We would recommend that suitable fire escapes be attached to all public school buildings, and that one be attached to each side of the building. Our children are housed in large frame structures, three, four and five stories high, and while it is true they have what is termed a fire drill, yet it is our opinion that should a fire occur they would become panic-stricken and many be killed or wounded."

The report recommends the establishment of a builders' bureau to be placed in charge of a competent builder or architect, whose sole duty will be to overlook all plans and specifications of new building, improvements or repairs. It is also recommended that the fire alarm station be removed from Chinatown and placed in the dome of the new City Hall. The report finds that some of the theatres are poorly protected from fire. The suggestion is made that a detail of three or four firemen be kept on duty during the progress of each entertainment. The men could be behind the scenes. This report is signed by E. B. Farnsworth, Chairman; W. L. Asbe and D. B. Factor.

The Committee on Health Department and Hospitals in its report scores the management of the City and County Hospital. It says:

"We have visited the City and County Hospital on several occassions, and must say that the sewerage system and the plumbing and ventilating of the different wards and corridors are a disgrace to the city, and should be immediately remedied. We find that there are over three hundred patients and over eighty paid employees, besidee four internes and eight rated ward tenders, who receive no pay."

AS LUMBER can be bought at most any price, the combine being broken, we still continue the old lumber price list as a comparison can be drawn by buyers. Now is the time to build.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

APPORTIONMENT OF INDEBTEDNESS FOR BUILDING LIENS.—Where building material has been ordered for the construction of several houses on a certain tract of land, which, before all of the material has been delivered, or a lien filed, is subdivided according to the number of houses, the lien must be apportioned and charged pro rata against the houses.

Blanchard v. Fried, Sup. Ct. Ill., 44 Northeastern Rep. 880.

LIABILITY OF OWNER OF ELEVATOR.—The duty of those operating a passenger elevator is the same as that of a common carrier, to exercise the highest degree of care for the safety of passengers, or those about to become such; and it is negligence to allow the doorway to an elevator shaft, opening into a hallway in an office building in a city, to remain open and unguarded.

So. B. & L. Ass'n Lawson, Sup. Ct. Tenn., 37 Southwestern Rep. 86.

WHEN ARCHITECT IS NOT ENTITLED TO FEES.—An architect employed to prepare plans and specifications for a building, and furnish an estimate of the probable cost, is not, upon submitting the same, entitled to his fees, unless the building can be erected at a cost reasonably approximating that stated in such estimate.

In this case, the architect has estimated that the building would cost about $4,000, but when bids were obtained it was found that it would cost over, $7,000, and the other party refused to go ahead with the building, and also to pay the architect any commission, claiming that he was induced solely by the estimates of the architect to have the plans drawn.

Feltham v. Sharp, Sup. Ct. Ga., 25 Southeastern Rep. 619.

WHEN LANDLORD IS LIABLE FOR TEARING DOWN ADJOINING BUILDING.—Where a landlord, who owned another building adjoining that occupied by his tenant, the two being constructed together, tore such building down, rendering the leased building unsafe, and then procured its condemnation and destruction by

the city authorities, such acts constituted an eviction, for which the tenant may recover damages, and the landlord cannot avail himself of the action of the city authorities as a defense.

Silber v. Larkin, Sup. Ct. Wis., 68 Northwestern Rep. 406.

Disclosure of Interest to Build by Architect.—An architect employed to furnish plans for the erection of a building, occupied by tenants, is not liable to the owner by disclosure of cintended erection of thenew buildings, the architect having neither ontracted, nor been requested, to keep such fact a secret, for the loss of rent caused by the vacation of the premises by the tenants.

Havens v. Dononue, Sup. Ct. Cal., 43 Pacific Reporter, 963.

Contractor can Recover Though Building Destroyed by Fire.—A contractor for the carpenter work in a building in the course of erection is entitled to recover from the owner the value of the materials used and the work done by him, where the building was destroyed by fire before the contract was completed; but he is not entitled to recover for the value of materials which he had procured to use in the house, but which had not actually been used at the time of the fire.

Hayes v. Cross, Sup Ct. App. Div., 40 N. Y. Supp. Rep. 1098.

HYDRAULIC POWER FOR CITY SUPPLY.

THE distribution of hydraulic power in London is the biggest thing of its kind in existence. It is not only unique in the sense of being the largest distribution of power from central stations in any city in the world, but it is excluding smaller installations in other cities, the only instance of a power distribution which furnishes exclusively a power supply. In other systems, viz, gas, electricity and steam, the main intention is to supply light and heat, the supply of power being only subsidlary. Even the compressed-air supply in Paris, which is the nearest in idea to the hydraulic supply in London, is dependent largely upon its lighting business. Hydraulic power in London and other cities is also interesting in another way, in so much that it depends not only exclusively or mainly on the supply of power alone, but that the supply was originally intended to serve and is, in fact, almost entirely used for one special class of business, viz, that of lifting. The lowest rate charged for hydraulic power in London is 1*s.* 6*d.* per 1,000 gallons. The pressure is 750 pounds per square inch, so that each 1,000 gallons contains 8,738 horse-power hours of energy; 1*s.* 6*d.* per 1,000 gallons is, therefore, equivalent to, say, 2*d.* per horse-power hour. It is only the largest hydraulic plants, pumping 20,000,000 or more gallons per quarter, which are capable of pumping at this cost, if to the actual pumping expenses are added the interest and depreciation on the capital value of the plant and the value of the space occupied by it. The largest private pumping plants existing in London are at the railway goods-depots, and at one of the principal and most modern of these depots, at which over 100,000,000 gallons per year are pumped, the pumping cost, exclusive of interest and other charges, is 9*d* per 1,000 gallons, and the total cost would be very little, if at all, below 1*s.* 6*d.* per 1,000 gallons.—*E. B. Ellington in Cassier's.*

THE NATIONAL ASSOCIATION OF BUILDING INSPECTORS

BUILDING INSPECTORS FOR THE CITY OF BUFFALO.

THE CHARTER of the city of Buffalo requires that building inspectors shall be practical building mechanics of at least five years' experience in their trade.

Previous to August 1, of this year, the city had four inspectors, one each of masonry, carpentry, plumbing and iron work. Early in the spring the city aldermen and council passed a resolution for the appointment of four additional inspectors and one structural engineer. A civil service examination for these positions was held, and four men were recommended by the commissioners. These men were the only ones qualifying out of about twenty-five who entered the examination. Two of these men were building superintendents for prominent architects in the city, another was a man who has had twenty years' experience in the mason business, acting as superintendent of masons and carpenters and estimator, and for several years was in the business himself. None of these three had ever been on the work laying brick, sawing timber or engaged in the work of a journeyman mason or carpenter. The fourth successful candidate was a man who had learned his trade as carpenter and had been subsequently, for many years, an architect.

The four men were appointed by the Board of Public Works to fill the newly-made positions, and began their duties on August 1. Time passed and pay day came. The pay roll of the Bureau of Building was passed as usual, except the part of it which related to the three building inspectors, who were declared to be not practical building mechanics of five years' experience. The contention arose that these men were practical building mechanics. Some of the councilmen believed that the men were not building mechanics, were ineligible for appointment, were illegally appointed and should be removed. On these grounds their pay was held as regularly as the pay roll appeared before the Council for approval. The question to be decided was: What is a building mechanic, and what did the framers of the charter mean by the expression in the charter above quoted? The civil service commissioners held that they were eligible for the position. The Board of Public Works was asked to hold an investigation, which resulted in the men being declared eligible and competent to fill the positions. The Council committee held an examination and as a result recommended the removal of the inspectors. The Council was divided in its opinion and asked the Corporation Counsel for his opinion on the matter. That gentleman thought over the same for three weeks, and in a length document handed his decision to the Council to the effect that the men were competent to fill the positions, but were not practical building mechanics, and, therefore, should be removed. The inspectors are still holding their positions, waiting for the proper authorities to remove them.

Building superintendents throughout the country are invited to discuss this question in these columns, giving the requirements for inspectors of buildings in their several cities.

"Do you like colored servants?" "It depends on the color. I don't care for green ones."—*Harper's Bazar.*

Edward B. Hindes & Co., 411 Mission street, San Francisco, is the place to go if you want Hill's Patent Inside Sliding Blinds, Perfection Window Screens, Latest Improved Venitian Blinds or Patent Self Rolling Burglar and Fire Proof Steel Shutters and Rolling Wood Partitions.

The Nurse (smiling)—Well, "it" is twins. WHEELER (crushed)—Havens! I hope bicycles will be cheaper next year.—*Puck.*

The Model Window Hinge is the only portable hinge extant. It is applied to windows so that they may be swung inside the room, in order that the outside of the glass may be cleaned without the necessity of sitting upon the window sill—a most tedious, uncomfortable and dangerous method of window cleaning. The hinge may be applied to old windows as well as new.

This hinge is simple in mechanical construction, and easy in operation. The hinges remain upon the window only while the latter is being cleaned, they being entirely re-

moved when not in use, leaving the window precisely as before.

The Model Window Hinge Company, the owners of this valuable patent, have obtained patents for the United States and Canada, and are now getting their patents in European countries and Australia.

This appliance has been placed on a great many buildings in San Francisco, Oakland, Portland, Tacoma, Fresno, San Jose and elsewhere and has met with the hearty approval and indorsement of all who have used it, including many of the leading architects of this city.

The following diplomas and special awards have been received by the Model Window Hinge Company, as evidence of the meritorious qualities possessed by this hinge:

Twenty-eighth Exposition Mechanics' Institute, San Francisco, Cal., 1895. Highest Award. The Oakland Exposition, Oakland, Cal., 1895. Gold Medal. The Oakland Exposition, Oakland, Cal., 1896. Diploma. Twenty-ninth Industrial Exposition Mechanics' Institute, [Home Products Exhibition] San Francisco, Cal., 1896. Diploma. Special Mention.

A few of the residences and prominent buildings in which the Model Window Hinge has been placed are: The Chronicle Building, A. B. McCreary's Building, 310 Pine street; second story Girl's High School; City and County Att'y Creswell's office, City Hall; J. Faulkner, 1217 Sutter street; A. P. Black, Asst. Pros. Att'y 1316 Green St.; Cerf Weyl, 1219 Sutter St; J. M. Young, 220 Kearny St; Geo. Cohn, 264 Battery street; L. H. Moise, Fulton near Fillmore; H. B. Russ, 14 Columbia Square; Mrs. J. Barron, 822 Broadway; John Yule, East Oakland; Chas. Parcells, Webster street, Oakland; William J. Kitto, 690 31st street, Oakland; Liverpool, London & Globe Building, Liedesdorff and California Sts.; Kohler Building, Jones and Sutter Sts.; City Hall, San Jose; Court House, Fresno; J. Weyl, 224 Kearny street, San Francisco.

Experienced mechanics are employed by the company to fit its appliance on buildings, and the work is done with neatness and dispatch, and without disturbing the usual routine of the household or the office. One set of the hinges is sufficient for the entire building, thus materially lessening the expense of adopting the hinge.

A sample window can be seen in operation in the office of the company, Mills Building, floor 7, room 5.

CITY BUILDING NEWS.

Belvedere near Fredrick. To build; owner, Otto T. Hildebrecht; architect, F. P. Rabin; contractor, D. Currie; cost $2654.

Bryant and Solano. Two-story frame; owner, Richard Schmuttenhaus; architects, Martens & Coffey; contractors, Franz & Burmeister; signed, Dec. 23; filed, Dec. 28; cost $3568.

Clay near Baker. Excavations, cement work, etc., for three-story frame; owner, F. F. Leitz; architect, C. A. Meussdorffer; contractor, R. H. Stettin; cost $1165. Plumbing; contractor, H. Williamson; cost $960. Carpenter work; A. Olson; cost $6983. Brick and iron work; contractors, T. Hock & Son; cost $650.

Eighteenth and Dolores. Excavating, etc.; owner, Board of Education; architect, C. I. Havens; contractor, Rae Building Co.; signed, Dec. 31; filed, Jan. 2; cost $123,908. Plumbing, contractor, T. C. Sweeney; cost $1,033.50. Heating; contractor, W. Morgan & Co.; cost $8496.

Eighteenth and Dolores. Hills' Patent Blinds for three-story brick; owner, Board of Education; architect, Chas. I. Havens; contractor, Edward B. Hinds; cost $2600.

Fair Oaks and 25th. To build; owner, John W. Smith; architects, Martens & Coffey; contractor, Wm. J. B. Warner; cost $3030.

Franklin and Washington. Alterations and adpitions; owner, Louis Cohen & Son; architects, Salfield & Kohlberg; contractor, H. Behrens; cost $1000.

Freelon near 4th. Two-story frame; owner, J. F. Dorland; contractor, A. Petry; signed, Dec. 22; cost $2100.

Fremont near Howard. Excavation and brick work for two-story brick; owner, Alexander P. Cristie; architect, David C. Coleman; contractor, Matt V. Brady; cost $1597.50.

Gilbert near Brannan. To build; owner, Con. Sweeney; architect, A. J. Barnett; contractor, Ed. Mooney; signed, Jan. 12; filed, Jan. 13; cost $1650.

Jackson near Fillmore. Excavation, etc., for two-story frame; owner, Mrs. Reba Levy; architect, M. J. Lyon; contractor, John Furness; cost $6450.

Lyons near McAllister. Two-story frame; owner, M. Meyer; contractors, T. & W. H. Kinread; cost $1250.

Pacific Ave. and Pierce. Two-story frame; owner, Samuel B. Welsh; architect, E. A. Mathews; contractors, Lieter & Prugh; cost $6938.

Park Road near Frederick. Two-story frame; owner, Richard Spreckles; architect, Edward J. Vogel; contractors, White Bros.; signed, Dec. 21; filed, Dec. 28; cost $6550.

Pierce near McAllister. Two-story frame; owner, L. Frielander; contractor, W. H. & T. Kinread; cost $1627.

Pine near Buchanan. Two-story frame; owners, G. H. and Mary G. Brown; Brown; architects, Townsend & Wyneken; contractors, Holm & Shelbly; signed, Dec. 30; filed, Dec. 31; cost $1807.

Pine near Buchanan. Alterations and additions; owner, J. O'Leary; architects, Townsend & Wyneken; contractor, Q. Powers; cost $1445.

Pine and Laguna. Alterations and additions; owner, Jane Burkhead; architects, Cahill & Condon; contractors, Knox & Cook; cost $2500.

Russ near Folsom. Alterations and additions; owner, H. Marks; architects, Salfield & Kohlberg; contractor, H. Behrens; cost $1670.

Sacramento near Steiner. Two-story frame; owner, A. Morris; architect, F. B. Wood: contractor, Jas. H. Burke; signed, Dec. 31; filed, Dec. 31; cost $3450.

Sixth near Channel. Two-story frame and lumber sheds; owner, Pacific Lumber Co.; days' work; cost $2000.

Twelfth Ave. near California. Cottage; owner, A. Vogel; architect, A. Vogel; contractor, A. McLauchlin; cost $1200.

Twenty-second near York. Two-story frame, six flats; owner, Wm. Torjet; contractor, Wm. Helbing; cost $4725.

Union near Scott. Two-story frame, owner, J. W. Valentine; architect, Edgar A. Mathews; contractor, Andrew T. Ruch; cost $3986.

Van Ness Ave. and Clay. Plate glass; owner, Claus Spreckels; architects, Reid Bros.; contractor, W. P. Fuller & Co.; signed, Nov. 19; filed, Dec. 31; cost $1800.

Washington near Leavenworth. Alterations, etc.; owner, Mary A. Runyou; architect, W. O. Banks; contractor, Geo. H. Walker; cost $2020.

SAUSALITO

Additions to three cottages. Owner, Mrs. L. Miller; architect, W. J. Cuthbertson; contractor, Jno. Mason; signed, Jan. 12; cost $1348.

OLIVER EVERETT Secretary.

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

THERE is a bill pending before the Legislature making it obligatory to provide definite plans for proposed bridges, in order to enable all bidders to estimate on the same plans and specifications.

This is a great improvement on the old method where the authorities require bidders to furnish their own plans, and as a consequence the contractor who furnished flimsiest and cheapest design, usually secured the contract. But there is no reason why the plans for public buildings required by the counties should not come under the same or a similar law, and we again call the attention of our law makers to the draft of a bill published in our December number outlining a method of obtaining plans for State buildings, and suggest to them that such provisions be adopted into the County Government Act, putting bridges under the caption of Engineering work, and buildings under the head of Architectural works.

FROM THE THIRD BIENNIAL REPORT OF STATE MINERALOGIST—STRUCTURAL MATERIAL.

CONTINUED FROM LAST NUMBER.

Forrester's Brickyard.—It is in Los Angeles, and uses an open kiln, fired with wood, coal and oil. Its capacity is 8,000 bricks a day. Six men are employed. C. Forrester, of No. 125 W. Second street, owner.

Gamble's Brickyard.—It is at Garvanza. An open kiln, fired with wood, is used. Its capacity is 8,000 bricks a day Eight men are employed. J. M. Gamble, of Garvanza, owner.

Houlahan & Griffith's Yard.—It is at Inglewood. They employ two Boenehke continuous kilns, fired with oil and coal. Capacity, 12,000,000 bricks a year. Sixty men are employed. Houlahan & Griffith, of No. 208 Stimson Block, owners.

Jensen's Brickyard.—It is in Los Angeles, and uses open

kilns, fired with wood. Capacity, 38,000 bricks a day. Thirty men are employed. H. Jensen, of No. 130 W. Second street, owner.

Joyce's Brickyard.—Located at Los Angeles. A continuous kiln, fired with coal, is used. Capacity 24,000 bricks a day. Thirty men are employed. T. F. Joyce, of No. 125 W. Second street, owner.

Karr, Frampton & Co's Brickyard.—It is at Los Angeles. Uses an open kiln, fired with oil. Capacity, 16,000 bricks a day. Eighteen men are employed. Karr Frampton & Co., of No. 125 W. Second street, owners.

Los Angeles Pressed Brick and Terra Cotta Co's. Works.—They are located at Los Angeles. Employ five down-draught kilns, fired with an oil "distillate" of 24° B. Twenty men are employed. Company's office, No. 119 S. Broadway; L. F. Miller, superintendent.

Monarch Brick Co.'s Yard.—It is at Los Angeles. Uses open kilns, fired with wood and oil. Capacity 34,000 bricks a day. Thirty men are employed. Whitman & Workman, of No. 127 W. Second street, owners.

Pay Brickyard.—It is at Los Angeles, and uses open kilns, fired with wood. Capacity, 18,000 bricks a day. Twenty men are employed. C. Pay, corner of Mott and Seventh streets, Boyle Heights, owner.

Pierson & Anderson's Brickyard.—It is at Los Angeles. Uses an open kiln, fired with wood and coal. Capacity, 8,000 bricks a day. Eight men are employed. C. Schroder, of Pico Heights, owner.

Simon's Brickyard.—It is at Los Angeles. A Hoffman continuous kiln, fired with coal-slack and wood, is used. Capacity, 25,000 bricks a day. Thirty men are employed. R. Simons, of E. Seventh street, near Boyle Avenue, owner.

MARIN COUNTY

There are three large brick plants in this county, all within a few miles of San Rafael, and accessible to tidewater. They were fully described in our XIIth Report, p. 382, and are as follows: The *Fortin Brick Co.*, the *Patent Brick Co.*, and the *Remillard Brick Co.*

MONO COUNTY

Gorman's Deposit.—It is 1 mile S. E. of Bodie, and is very extensive, proven by a 190′ tunnel and various cross-cuts. It is hard ank soft in places, of many colors, and estimated to be 60′ to 80′ thick. Locally used for brick. Hugh Gorman, of Bodie, owner.

PLACER COUNTY

Gladding, McBean & Co.'s Potteries.—See our IXth and XIIth Reports, pp. 297 and 382. They are at Lincoln, at 170′ elevation. All sorts of architectural terra cotta, vitrified sewer-pipe, 3″ to 30″ in diameter, vases, flower-pots, hollow tile, fire-proofing, pressed and fire brick, etc., are made. The works consist of a 150 H. P. engine and 4 boilers; 16 down-draught kilns; the necessary mixing, grinding, and pugging mills, etc.; and a Boyd's brick-press, for manufacturing pressed brick in the semi-dry way, has been recently added and is in successful operation; 80 tons pressure is said to be applied on each brick. A large quantity of fuel is required. The supply of wood is decreasing, and is being replaced by oil under the boilers and coal in the kilns. The clays (kaolin) used are principally obtained from two large pits at the eastern end of a low ridge 1 mile N. of the pottery. The following section is shown in the southern pit:

Soil	1′
Volcanic breccia	12′
Light, sandy clay	8′
Fine sand	4′
Sandy yellow clay	7′
Sandy clay with gravel	6′

The following section is in the northern pit:

Soil, etc	2′
Volcanic breccia	10′
Fire-clay (for fire-proofing, etc.)	10′
Pipe-clay (for sewer-pipe, etc.)	6′
Fine white terra cotta clay	20′

The clay is excavated in the northern pit to a depth where water interferes. The extent of the deposit is unknown. A hole 60′ deep, bored in the bottom of the pit, is said not to have reached the bottom of the clay, and it is said to underlie the town of Lincoln, where it has been penetrated by wells. One hundred and fifty-six men are employed. J. R. Chambers, of San Francisco, secretary; A. J. Gladding, of Lincoln, superintendent.

RIVERSIDE COUNTY

Elsinore Coal and Clay Co.'s Works.—They are 6 miles W. of Elsinore at 1,200′ elevation. The several pits are near the Elsinore (*Chaney*) coal mine. About 5,000 tons of clay have been shipped to manufacturing establishments. Should the Southern California R. R. extend its tracks to this locality the industry is likely to become one of importance. D. W. McCrea, of Elsinore, superintendent.

McKnight's Clay Works.—It is 4 miles S. W. of South Riverside, at 1,200′ elevation. The clay is of the indurated variety, and occurs as a bed in the Tertiary rocks, having a dip comformable to the sandstone. The clay-pits near Elsinore and in Temecula Canon are mostly Quaternary deposits. The clay is shipped to the pipe-works at South Riverside and to the terra cotta works at Los Angeles. The output at present is 200 tons per month. J. H. McKnight, of South Riverside, owner.

Pacific Clay Manufacturing Co.'s Works.—They are in Temescal Canon, 12 M. east of South Riverside. Several pits are opened in this locality and the clay shipped by waggons to South Riverside, where the pipe-works of the company are located. M. Findlay, of South Riverside, superintendent.

SACRAMENTO COUNTY

Capital Sewer-Pipe Works.—See our Xth Report, p. 509. They are in the eastern part of the City of Sacramento. They consist of two down-draught kilns, 18′ to 20′ in diameter, and a Vaughn sewer-pipe press, of 600 to 1,800 pieces daily capacity, depending upon the size of pipe. The clay used is obtained near Carbondale. Nine men are employed, George Muddox, of Sacramento, owner and manager.

Fountain Bros'. Brickyard.—See our Xth Report, p. 508. It is in the southern part of the City of Sacramento. A superficial deposit of loam, clay and sandy clay, 6′ thick is used for making bricks. It varies in character from loam at the top, through clay, to sandy clay at the bottom, which, by thoroughly mixing, forms good material for bricks. About 1,000,000 bricks are burned annually in common kilns. Ten men are employed when working. W. A. Fountain, of Sacramento, manager.

Kreuzberger & Harvie's (Ryan) Brickyard.—It is near Fountain Bros.' yard, in the southern part of the City of Sacramento. Dark sandy loam, 6′ to 10′ thick, is used; 200,000 bricks are burned per month, or 2,000,000 per annum, in common kilns. Twenty-four men are employed. N. Harvie, of Sacramento, manager.

Sacramento Transportation Co.'s Brickyard.—See our Xth and XIIth Reports, pp. 506 and 383. It is at Riverside, on the Sacramento River, 5 miles below the City of Sacramento. The works consist of five brick-machines of 30,000 daily capacity each; two sixteen-compartment Hoffman kilns of 50,000 daily capacity eoch; a dredger for excavating, and a railroad for transporting the clap from the pits to the works. A 12′ superficial deposit of loam, clay, and sandy clay is used. It is partially mixed by the steam shovel which fills the pits in the lowlands. The demand for bricks now being limited, the works are run intermittently. When running full-handed 160 men are employed, principally Chinese. Frank Dwyer, of Sacramento, secretary; J. O'Neil, of Sacramento, superintendent.

SAN JOAQUIN COUNTY

The agricultural industries are most important, and, with this fact in view, the Stanislaus and San Joaquin Water Co. developed their irrigation canals during the summer of 1895. Manufacturing industries about Stockton, where shipping facilities are good, are also very important sources of revenue. The natural economic mineral resources at present developed consist principally of the well-known natural gas at Stockton, manganese in the western foothills, and brick-clays near the San Joaquin River. A good supply of water may be had from wells, 80′ to 150′ deep, in most parts of the valley lands, and flowing wells are obtained throughout the central part of the valley at about 1,000′ in depth.

Fine, earthy clay occurs in places in the San Joaquin Valley, which, if properly selected, is suitable for making bricks. A number of clay beds suitable for bricks, etc., have been penetrated by wells in Stockton and vicinity, but their depth has prevented their exploitation.

San Joaquin Brick Co.'s (San Joaquin Improvement Co.'s) Yard.—See our XIIIth and XIth Reports, pp. 561 and 394 It is on the San Joaquin River, 5 miles S. W. of Stockton. The material used is a superficial deposit of fine, earthy clay, which contains enough iron to color the bricks bright red. The clay is mined by dredging; the bricks are made in a Potts machine of 40,000 daily capacity, and burned in a fourteen-chamber Hoffman kiln of 18,000 daily capacity; coal is used for fuel. Fifteen to forty men are employed. C. Horton of Stockton, secretary; F. W. Muller, of Stockton, superintendent.

Stockton Terra Cotta Co.'s Pottery.—See our XIth Report, p. 394. It is at Stockton. Terra cotta, sewer-pipe, etc., are manufactured. The clay used is mined at Valley Springs, Calaveras County. Idle. W. C. Morgan, of Stockton, superintendent.

SAN LOUIS OBISPO COUNTY

Ah Louis' Brickyard.—It is 1 mile W. of San Luis Obispo, at about 300′ altitude. Superficial loam is used; the bricks are made by hand, and burned in common kilns. About 800,000 are made per annum for the local demand. Eight Chinese are employed.

SANTA CLARA COUNTY

Dreischmyer's, H., Brickyard.—It is on Coyote Creek, in the suburbs of San Jose. Common stock and pressed bricks are made from a superficial deposit of sandy clay, and burned in a Hoffman kiln; 1,250,000 bricks were burned in the summer of 1895, and 25 men were employed.

Peterson's Brickyard.—It is on the S. P. R. R., in the southern part of San Jose. Common and pressed bricks are from a superficial deposit of sandy clay, 25′ thick, on Coyote Creek, 1 mile E. of the yard. Two patent kilns are used. About 300,000 pressed and 3,000,000 common bricks are made annually. Fifty-five men are employed in summer. T. W. Petterson, of San Jose, manager.

Remillard Brick Co.'s Yard.—It is on the east side of Coyote Creek, in the southeastern part of San Jose. Common stock and pressed bricks are made. The company owns 170 acres, on which is a heavy superficial deposit of clay suitable for making bricks. A Hoffman kiln is used. The clay is hoisted from the pit by steamer-power and transported in side dumping cars to the yards. The works were in operation four monts in 1895, and 60 men were employed. C. Sunard, of San Jose, superintendent.

San Jose Brick Co.'s Yard.—This company have two Hoffman kilns on the Narrow-Gauge Railroad, 1 mile W. of San Jose. A total of about 12,000,000 common and pressed bricks are produced annually. One hundred and fifty men are employed in summer and thirty in winter. J. M. O'Keefe, of San Jose, superintendent.

SANTA CRUZ COUNTY

There is a great variety of clays in this county that have only been tested in a few cases, and but little is known of their general utility. A large percentage of them are indurated, and occur in the form of argillaceous or clay shales. From their light color and general appearance they are locally known as "chalk rock," but are by no means a chalk. They occur in the hills and bluffs about Santa Cruz and elsewhere in the foothills facing the coast. Satisfactory experiments have been made with an indurated clay occurring in large masses, though undeveloped, on the *Hodge ranch*, 1½ miles S. W. of Glenwood, and near the railway. See our Xth and XIIth Reports, pp. 623 and 383.

McCabe Brickyard.—It is situated on the San Lorenzo River, about 1 mile N. of Santa Cruz. Three kilns were burned in the summer of 1895, producing about 422,000 bricks, principally used in the construction of the new court-house in Santa Cruz. The clay is 15′ to 20′ thick, overlies a bed of sand, and consists of the disintegrated mass of granite rocks and shales transported from above by water. Just sufficient iron is contained to give the bricks a bright red color. R. M. McCabe, owner; A. G. Bowman, of Santa Cruz, superintendent.

Hihn's, F. A., Brickyard.—See our XIIth Report, p. 383. It is on San Lorenzo Creek, near Felton. Seventy-five thousand bricks were burned in 1895.

SHASTA COUNTY

Holt & Gregg.—This firm has brickyards located at *Anderson* and *Redding*. At the Anderson yard, situated 2

miles N. of town, a 30,000 per day brick-molding machine is to put up. The past season, 400,000 bricks were burned. Melded and stock bricks are made by the firm, which employs in the busy season as may as 250 men; 30 men are at work at present. Holt & Gregg, of Red Bluff, Tehama County, owners.

SOLANO COUNTY

McKenzy & Reid's Pottery.—It is located in the town of Benicia, and only stove linings are manufactured. The clay worked is obtained principally from Ione, and a small quantity from Hoyt's farm, 1 mile N. of Goodyear's Station. The pottery is run intermittently, and 6 men are employed. J. McKenzy and M. Reid, of Benecia, owners.

Napa.—Clay of good quality and in large quantities exists, but is not utilized at present.

Union Pressed Brick and Terra Cotta Co.'s Works.—These extensive works are at Vallejo. There are four terra cotta and two brick kilns, with ample shed room. Idle. J. W. Pew, of No. 310 Pine street, San Francisco, secretary.

Vallejo Hydraulic Pressed Brick Co.'s Works.—They are 1 mile N. of Vallejo. They consist of a large Hoffman kiln, hydraulic pressed brick machine, steam engine, boiler, etc. Pressed brick were made from the clay shales obtained at the works. Idle. California Bank, of San Francisco, owner.

TULARE COUNTY

At Visalia are two brickyards, owned by T. B. Craycoft and George Ballu, of Visalia. Their combined capacity is about 1,000,000 bricks per year.

To be continued.

CORRESPONDENCE

To the Editor of the California Architect and Building News.

DEAR SIR:—I have not met yet with any rule for the proportion of Risers to Treads of Stairs which seems to be satisfactory generally.

One rule says that the sum of the Riser and Tread should equal 17½" for what reason it does not say.

Another rule starts at a proportion of Tread to Riser of 12" to 5½" and then goes on for every increase of 1" Tread a decrease of ½" Riser.

A third rule says Riser=66 divided by Tread, so that 12" Tread=5½ Riser and 9" Tread=7⅓" Riser.

For purposes of comparison I give the three tables—all in inches:

		No. 1	No. 2	No. 3
TREAD 9 inches	RISER 8½ inches	7 inches	7⅓ inches
" 10 "	7½ "	6½ "	6 2-5 "
" 11 "	6½ "	6 "	6 "
" 12 "	5½ "	5½ "	5½ "

By this it shows they all agree only upon the Riser for a 12" Tread—which forms the start from which they immediately diverge. Number 1 and number 2 stepping along in arithmetical progression, number 1 quicker than number 2, while number 3 goes at a hybrid geometric gait.

The third idea seems the most scientific, for as the steepness of the hill increases, the labor of going up increases in increasing Ratios, or with the same power the shortness of the step increases in a like ratio.

The practice in California is to make the steps a little longer than indicated by 12 to 5, for 12" Tread—possibly because the legs of Westerners are longer than others. The formula—Riser=69 divided by Tread would be nearer to these ideas—this would give the following table reduced to eighths:

Tread 8 inches	.....	Riser 8⅝ inches
" 9 "	.....	" 7⅝ "
" 10 "	.....	" 6⅞ "
" 11 "	.....	" 6¼ "
" 12 "	.....	" 5¾ "
" 12 "	.....	" 5¼ "

Would be glad to hear how this accords with practice of others.

Yours,

STROLLER.

To the Editor of the California Architect and Building News.

DEAR SIR:—The use of slate for roofing purposes is a subject that should engross more of the attention of our architects, contractors and builders. Some of the first named, for some reason known only to themselves, but which is directly contrary to the ultimate interests of those for whom they plan structures, seem to invariably make their specifications exclude the use of slate for roofing or when the owner insists upon slate being used, these architects will manage by some means to have the eastern product provided. The latter action is quite as grevious as it can be, for here in our own State, within one hundred and fifty miles of San Francisco, there are inexhaustible beds of slate of the finest quality. In color it is a beautiful blue black, flawless in every respect and of a most enduring character. This material can be shipped anywhere on this coast and delivered at a cost not greater than eastern or foreign slate, and in some respects for even less, when its superiority as a natural product is taken into consideration.

There is a certain sense of injustice to our own people manifested in these matters, and while every one is ready to cry for the protection of home industries, in the matter mentioned there seems to be a lack of home patronage. This is strikingly wrong regarding public structures where the strictest economy in the long run should prevail and the money of the people put to the best uses.

When the late Page Brown prepared his plans for the new Union Ferry Depot in San Francisco, he represented that a slate roof would be too heavy, and instead recommended the use of corrugated iron. Aside from the fact that the heavy iron frame is amply strong to sustain the weight of a slate roof, the idea of covering such a structure with unsightly corrugated iron ought to have been sufficient to reject his ideas. If this material is used the otherwise attractive building will have a cheap and unfinished appearance. This is not the only objection, for owing to its close contiguity to the water and its exposure at all times to the general humidity, the natural corrosion will be very rapid. In order to partly obviate this difficulty and protect the property, it will require painting every year at considerable expense, and at the end of a decade its service will have ended and a new roof be required to replace it. If slate was used instead, all these objectionable features would be removed; the structure would have the finished appearance it should possess, without any resemblance to a shed; it would never require painting and would last the life of the building itself. It is not even yet too late to remedy this glaring defect and a great advantage to the state in the way of economy would be gained if the plans were changed and an additional appropriation made to effect such a desirable object.

The contemplated roof for the City Hall is to be a combination of corrugated iron and concrete—a heavy cumbrous material not nearly so enduring as slate, and in the end ever so much more expensive. The proposed roof for the New Municipal Building on Kearny and Washington streets is to be of tar, felt, gravel, etc., something that will require frequent expense for repairs.

In contrast to these plans of the state and city compare the action of the Federal Government and its long row of recently erected new brick barracks at the Presidio, all covered with slate.

SLATE ROOFER.

HOUSING OF PEOPLE OF SMALL INCOMES.

No. 6.

BUILDING REGULATIONS CONTINUED.

N GLANCING over the Building Regulations—very often called by the narrower name of Fire Ordinances—of some of the large cities of the world including the City of San Francisco, we shall arrange the subject under three divisions, viz.: 1st Those regulations pertaining chiefly to the proper construction of building. 2d Those appertaining to the arrangement of building hygienically. 3rd Plumbing regulations.

FIRST—Pertaining chiefly to the proper construction of building:

In Paris the height of buildings bordering on public streets is determined by the width of the streets, and is measured from the sidewalk to the highest point of the front. The height cannot exceed 12 meters (39.37 feet) for streets 7.80 meters (25.59 feet) wide, 15 meters (49.21 feet) for streets from 7.80 to 9.74 meters (25.59 to 31.96 feet) wide, 18 meters (59.05 feet) for streets from 9.74 to 20 meters (31.96 to 65.62 feet) wide, and 20 meters (65.62 feet) wide. Buildings in any case may not comprise more than seven stories, not including the ground floor. The ground floor story must not be less than 2280 meters (9.19 feet) in height. The height of the other stories and the basement must not be less than 2.60 meters (8.53 feet). In case of attics it is sufficient if the hightest part is 5.60 meters (8.53 feet) in height. Courts of buildings not more than 18 meters (59.05 feet) high must have a surface of not less than 30 square meters (322.92 square feet) with an average width of not less than 5 meters (16.40 feet).

In Berlin no more than five stories will be permitted in buildings intended for permanent occupancy by human beings, and the flooring of the top story must never exceed a height of 17.50 meters (57.41 feet) above the sidewalk. The proposed New York rule is given in our Decembe journal.

In San Francisco on all streets 100 feet and more in width no building shall be constructed exceeding 125 feet in height. On all streets less than 100 feet in width no building shall be constructed exceeding 100 feet in height.

This is altogether too liberal and some more general law should be adopted, such as that of London where no building shall be higher than the width of the street.

In most cities regulations are made establishing a building line for residence parts of the city where the houses have front gardens; this prevents a selfish owner from building in front of his neighbor and should be ordained.

In the San Francisco Ordinance the smallest space allowed between bay windows is specially stated but not space allowed between bay windows or projections and adjoining property. The rule in Berlin is that all projecting constructions extending more than 30 centimeters (11.81 inches) beyond the building line must be kept separated from neighboring properties by a distance equal to at least one and one-half times the distance of the projection.

In the same way provision should be made for thickness of external walls when cut up by many openings. In Manchester whenever openings in external walls in any of the stories are greater than one-half of the whole extent of the vertical face, piers of brickwork or other fireproof supports must be so disposed as to carry the superstructure Piers of this kind must also be placed at the corner or angle of any street on which the building abuts. Openings in party walls are forbidden.

2d. In the matter of those regulations for the treatment of building hygenically—the following are a few of the points requiring consideration:

No street to be less width than forty feet.

No cellar to be used for any other purpose than for storage.

Back to back houses to be prohibited.

In Manchester when the floor of the lowest story of a dwelling house is below the level of the adjoining ground which is immediately in contact this story must be inclosed with double walls having an intervening cavity extending 6 inches above the surface of the ground, being at least 2¼ inches wide and properly ventilated. If the cavity is filled with asphalt it need only be 1 inch wide. The parts of this double wall must be properly tied together with iron, vitrified stoneware, or other suitable material, inserted at distances apart not exceeding 3 feet horizontally and 18 inches vertically. There must be also a damp course of sheet lead, asphalt, slates, or other impervious material at the base of such wall, and likewise at the top of the cavity. The aggregate thickness of the two parts of the double wall, exclusive of the cavity, must be throughout not less than the minimum thickness prescribed for a wall of the same height and length, and belonging to the same class of buildings as that to which the double walls belong.

The yards or open spaces in Manchester, in connection with dwelling houses, to the extent of 150 square feet, must be properly paved with durable and impervious pavement, laid closely and evenly and sloped to a channel leading to a trapped gulley grating so as to carry off all rain and waste water. This pavement is to be so arranged that it shall adjoin the external wall in the rear or at the side of the house, and where practicable it shall extend throughout a distance of 10 feet from said wall.

Fronts of buildings in Paris must always be kept in good

condition. They must be scraped, repainted, or washed at least once in every ten years, under penalty of a fine not exceeding 100 francs ($19.30).

In stables, in Berlin, the floor must be covered with an impermeable material. Sufficient and appropriate receptacles for the reception of stable manure must be provided at a proper distance from the stable. No stable will be permitted to have any openings facing a public street.

In the construction of tenement houses not more than 78 per cent of the ground of the lot shall be covered

The regulations of New York governing the Lighting and ventilation of dwellings are as follows:

VENTILATION OF ROOMS

Every habitable room must have at least one window opening directly upon the street or yard, or upon a court or light shaft.

LIGHT AND AIR SHAFTS

Except as hereinafter otherwise prescribed, every light and air shaft for habitable rooms must be at least 12 square feet in area for a three-story house, 16 square feet in area for a four-story house, and 20 square feet in area for a five-story house; and in every case not less than 2 feet wide in the clear. Shafts or courts between two houses and common to both, must be of double this area, and not less than 4 feet wide. But in houses where there are five interior rooms in a line on a floor, the area of shafts must be 50 per cent greater than above perscribed; and where there are six interior rooms in a line on a floor, the area of each shaft must be at least 100 per cent greater than the minimum above prescribed.

And in every tenement house with apartments on five or more floors, and having more than twelve rooms on a floor, to be erected on an ordinary city lot, except a corner lot, the courts to light and ventilate interior rooms must have an area of at least 265 feet; and where there are twelve rooms on a floor, the area of such courts must be not less than 215 square feet.

WINDOWS

The windows of habitable rooms which open on shafts or courts must be hung with weights so as to slide vertically, each window to be not less than 12 square feet in area.

VENTILATION OF WATER-CLOSET COMPARTMENTS

Water-closets shall not be ventilated by a shaft which ventilates habitable rooms; and where they do not open otherwise to the external air, they must be ventilated by means of a separate shaft, not less than 3 square feet in area, to extend above the roof, and arranged for the admission of light and air at the top in like manner as the shafts for rooms.

WATER-CLOSETS ETC.

No privy vault or cesspool shall be allowed, if water-closets can be connected with the street sewer. At least one water-closet shall be provided for each two families. The general privy accommodation shall not be placed in the cellar,

YARDS AREAS, ETC.

Yards, areas, cellars, and light courts shall be properly graded and drained and flagged or concreted.

ATLERATIONS AND ADDITIONS

No alteration in the light and ventilation of the premises for which this permit is granted shall be made, except upon the express written approval of the superintendent of buildings; nor shall any additional structure be erected upon the lot except upon such approval and a special permit.

3rd. Plumbing Regulations—In New York these are put in force by the Department of Buildings where they properly belong and not to the Department of Health.

No tenement house can be erected until the plans for light and ventilation have been approved, nor can the plumbing and drainage of any building be executed until the plans have been approved by the department. The specifications for plumbing and drainage are exceedingly minute.

SPECIFICATIONS FOR PLUMBING AND DRAINAGE

GENERAL DIRECTIONS

It is expressly understood that these specifications and the drawings submitted herewith to the department of bnildings for approval constitute together, as approved by said superintendent of buildings, the plans for the plumbing and drainage of the buildings herein described; and in respect to all work not covered thereby the plumber is to be governed by the rules and regulations as to plumbing and drainage established by the superintendent of buildings.

The plumber will furnish all materials and perform all labor requisite and necessary for putting up and completing all the plumbing work in a good and thoroughly workmanlike manner, according to the plans therefor as approved by the superintendent of buildings.

All material will be of good quality and free from defects.

The diameter of pipes herein specified are inside diameters.

The —— will properly close all openings in floors and ceilings about lines of drain and vent pipe, so as to prevent the passage of foul odors from one floor to another along said line of pipe.

The plumber will send notice to the superintendent of buildings when the work will begin, and also at various times during the progress of said work before any part of it is permanently covered.

The plumber will properly protect all pipes and fixtures as soon as set, and close all pipe openings so as to prevent obstruction and damage.

The —— will do all the excavating and refilling required for the proper carrying out of these specifications, except as such work is herein otherwise specially provided for.

The plumber will obtain and pay for all necessary permits, and comply with all corporation laws relating to the subject-matter of these specifications.

After the completion of the work under the plans and specifications, and before its final acceptance, the plumber must obtain the certificate of the superintendent of buildings

ST. GILES, CHEDDINGTON,
KENT, ENGLAND.

PAPST CAFÉ. COR. POWELL AND ELLIS STREETS

DE PROSSE & MEUSSDORFFER, ARCHITECTS

that there is no violation of law on record against said work, and also a water permit from the department of public works. He will then turn on the water and leave everything in perfect working order.

I—MATERIALS, ETC.

EARTHENWARE PIPE

All earthenware pipe herein specified must be hard, smooth, salt glazed, and cylindrical, and not less that three-fourths of an inch in thickness. Each length will be perfectly straight and free from any fire cracks, flaws, blisters, or other defects.

All special fittings to be of the same quality as the pipe.

CAST-IRON PIPE.

All cast-iron pipe and fittings must be sound, cylindrical and smooth, free from cracks, sand holes, and other defects, of a uniform thickness, and of the grade known in commerce as extra heavy. All iron pipe will be firmly secured in position by proper pipe supports placed not more than 5 feet apart. No tar-coated pipe will be used, but after the pipes have been tested and accepted by the inspector they will be coated with ——.

The following average weights per linear foot will be accepted:

	Pounds
2 inches	5½
3 "	9½
4 "	13
5 "	17
6 "	20
7 "	27
8 "	33½
10 "	45
12 "	54

All joints in cast-iron pipe will be made with picked oakum and molten lead, and the plumber will make the joints impermeable to gases by bedding the lead with hammer and calking iron. For each joint in cast-iron pipe 12 ounces of lead must be used to each inch of diameter of the pipe in which the joint is made. No putty or cement joints will be permitted. The lead used for calking will be pure, soft pig lead; no old joints or other defective material will be used.

WROUGHT-IRON PIPE

(If any wrought-iron pipe is to be used in the plumbing and drainage of the buildings it should be here specified.)

LEAD-PIPE

All branch lead soil, waste, and vent pipes, including bends, must be of the best quality and of not less than the following weights per linear foot.

Diameter	Weight per foot lbs. ozs.
1½ inches	3 8
2 "	4
3 "	6
4 "	8

All connections of lead with iron pipes will be made by heavy brass ferrules of the same size as the lead pipe, set in the hub of the branch of the iron pipe and calked in with lead, the lead pipe to be attached to the ferrule by a proper solder-wiped joint when practicable. No putty or cement joints will be permitted.

All connections of branch lead pipes will be made by wiped joints.

All lead pipes will be firmly secured in place with hard-metal tacks and screws, placed not more than 3 feet apart, and all horizontal lead pipes will be well supported for their whole length by shelves or carrying strips, to be provided and put up by ——.

[Most of the information in these series of articles is culled from the Eight Special Report of the Commissioner of Labor, U. S. A.]

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street.

SETH BABSON, Pres. — W. P. MOORE, Vice-Pres.
OLIVER EVERETT, Sec. — JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

THEO. A. EISEN, PRES. — ARTHUR B. BENTON, Vice-Pres.
WILLIAM C. AIKEN, Sec'y. — AUGUST WACKERBARTH, Treas.

WASHINGTON CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

JOS. C. HORNBLOWER, Pres. — JAS. G. HILL, Vice-Pres.
E. W. DUNN, JR., Sec. — W. J. MARSH, Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.

E. J. MOLERA, Pres. — W. F. C. HASSON, Vice-Pres.
OTTO VON GELDERN, Sec. — EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.

JAS. E. BRITT, Pres. — J. L. E. Firman, Sec.

BUILDERS' EXCHANGE, Directors meet first Friday in each month at Mission and New Montgomery.

OSCAR LEWIS, Pres. — JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday evening of each month.

ADAM BECK, Pres. — M. V. BRADY, Sec.

BOOKS AND PERIODICALS.

—THIRTEENTH REPORT OF THE STATE MINERALOGIST for the two years ending September 15, 1896. California State Mining Bureau. J. J. Crawford, State Mineralogist.

A very exhaustive well arranged and useful report, reflecting great credit on Mr. Crawford its compiler. It also includes the report of the trustees of the State Mining Bureau and a memorial notice of J. Z. Davis, who died Oct. 28th last and was one of the trustees and a large contributor to the Museum and Library and took a large interest in the success of its Bureau.

The statistical tables and information are very thorough and exhaustive and includes the field assistants' mineralogical reports from every county in the State condensed into concise blocks.

Nineteen thousand five hundred and eight men are now engaged in mining and quarrying in the State while the total value of all mineral products is $22,844,644.

While gold still continues to be by far our largest mineral product, the annual value of our non-metallic substances has now reached $1,348,280; hydrocarbans and gasses, $1,404,321, and structural materials, $2,713,755. It is worthy of note that in addition to the precious metals there were 36 other mineral substances produced.

The great value of these reports are attested by the demand for copies, which soon depletes the edition—the recommendation of having them stereotyped is a good one. Another recommendation of Mr. Crawford's also deserves attention when he says:

"If possible, this Bureau should be placed upon a permanent basis in regard to funds, the same as the University, etc., in order to produce work of a superior character. As long as it leads an ephemeral life, existing from Legislature to Legislature, it is impossible to undertake certain lines of scientific work that the character of the institution demands, and which might otherwise be stopped, if commenced, through lack of funds."

Besides the Biennal Reports this Bureau issues Bulletins at intervals. During the present Administration the following have been issued: Bulletin No. 2—Mine Timbering by W. H. Storms; No. 3—Gas and Petroleum Yielding formations of the great valley of California by W. L. Watts; No. 4—Catalog of California Fossils by Dr. J. G. Cooper; No. 5—The Cyanide Process, its Practical Application and Economic Results by Dr. A. Scheidel, E. M.; No. 6—Cal. Gold Mill Practice by E. B. Preston, M. E.; No. 7—Mineral Statistics of California for year 1894 by Chas. G. Yale; No. 8—Mineral Productions of California for 1895 by same; No. 9—Mine Drainage, pumps, etc., by Haus C. Behr; No. 10—A Bibliografy relating to the Geology, Palœontology and Mineral Resources of California by Capt. A. W. Vogdes; No. 11—The Oil Yielding Formations of Los Angeles, Santa Barbara and Ventura Counties by W. L. Watts.

In the latter part of this volume will be found original papers of great interest and instruction. The able article on "Compressed Air," by Arthur De Wint Foote, will direct attention to this most important means of transmitting power, and will enable the student to compare its efficiency and economy with that of electricity.

The value of the article on "Timber Preservation," contributed by John D. Isaacs, Chemist incharge of the Southern Pacific Company's (Pacific System) timber-preserving plants, can hardly be overestimated.

Dr. Salathe's paper will prove a valuable acquisition to the technical literature on the subject of the rapidly growing industry, petroleum. His researches are extensive and have never before been given to the public.

The very excellent article by W. F. C. Hasson, Electrical Engineer, on the several electrical transmission plants in successful operation in this State, together with the numerous illustrations, will prove a valuable addition to this class of literature. It is given in a full, yet concise and practical form, that will be appreciated by business men.

The portion of the report devoted to structural materials is of peculiar interest to architects, engineers and builders—and we shall make liberal excerpts from the same for the benefit of those of our readers who may not be able to get a copy of the full report.

LIPPINCOTTS' MAGAZINE for February, 1897, contains the complete novel "Under the Pacific" by Clarence Herbert New. A very improbable story at the same time very interesting and extremely charming at the end.

The FORTNIGHTLY REVIEW for January contains a defence of Cornelius Herz, at one time a resident of this city, from the charge of fraud in connection with the Panama Canal scandal. The writer makes out a very fair showing for Dr. Herz, who appears to have been selected as a scape-goat for those high in authority in France. The fact that after a long detention in England at the request of the French Government no proof being brought forward against him he was allowed to go free confirms the view of the writer that he was unjustly treated by both the French and English Governments.

Proceedings of the THIRTIETH ANNUAL CONVENTION AMERICAN INSTITUTE OF ARCHITECTS—Held in the rooms of the Engineering Association of the South, Nashville, Tennessee, Oct. 20th, 21st and 22, 1896. This number contains an engraving of Geo. B. Post, pres., and contains a full report of the proceedings of the convention, which cannot fail to be of interest to the architects all over the country.

SAN FRANCISCO MUNICIPAL REPORT for the fiscal year, 1895–96, ending June 30, 1896, published by order of the Board of Supervisors. This bulky volume contains beside the usual reports of the various city officers, a fine engraving of the New City Hall as well as the protraits of our late Mayor and Supervisors.

If not an interesting document it is certainly a valuable one as a record of what has been done during that year.

SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS.

THE business of the Chapter at the February meeting was the consideration of a paper by Mr. G. A. Wright, a quantity surveyor, entitled "Bills of Quantities and Their Relation to Contracts," on the many advantages that would result to all concerned, if such a system as outlined in the paper could be introduced.

A number of architects and contractors discussed the pros and cons of the question but the important matter of deciding who would or should pay for the expense of preparing the quantity estimates was not decided, although all present agreed that it would be a great convenience, and save much waste of time to contractors and lessen the chance of errors in estimating. The contractors argued that as they gave their time to estimating on plans for the benefit of the owner, the latter should bear the cost. The architects were positive that the amount of their present compensation was all that could be collected from clients and that it would not be practicable to directly tax them the additional one or two per cent that would be necessary to defray the fees of the quantity surveyor, and the result will be that the present customs will continue till the contractors interested combine for their own benefit, and refuse to estimate on work unless a bill of quantities accompanies the plans.

PAPST CAFE.

THE building which is the subject of our illustrations this month is the newly completed Pabst Cafe, located on the north east corner of Powell and Ellis streets.

The building is four stories in height, designed by architects De Prosse & Meussdorffer, and faces the Baldwin Hotel on one corner while diagonally opposite the "Auzerais" on the other.

The architects have planned a very creditable structure, carefully studying the Rococo details which decorate the facades; yet though the ornamentation is elaborate, it is in excellent taste and the danger of overloading the fronts has been skillfully avoided. The entrance on the corner is circular in form, and this plan has been successfully carried up as a dominating motif in the design, terminating in a well proportioned dome.

It is not out of place when a pleasing building has been effectively carried out to give the general public some information as to the individuality of those who have by their exertions carried out the ideals of the designers and made them real and substantial.

It is but just that they should receive some credit for their care and skill, and to those of our readers who are not familiar with the details of the constructive arts, it will be of considerable interest to follow in imagination some of the many and varied trades and arts, craftsmen, and mechanics, who have contributed time and labor, strength and skill, to produce such a modern business structure as we show. Few people outside of those directly employed on the building, fully realize how numerous and varied are the different kinds of labor both skilled and unskilled, that are here brought together. Passing over the great amount of preliminary work done by the architects in preparing the plans, specifications and detail drawings, the first man directly employed is the surveyor, who gives the points, lines and grades establishing the site of the building and its starting points with relation to the street levels—next in order is the grader with his carts and wagons who excavates for the subterranean portions of this building and prepares the trenches for the foundation walls—then comes the Master Mason, in this instance J. Ferd Wagner of 154 Clara Ave., who lays out the work and instructs his assistants how to most economically handle the men and dispose of the materials, seeing the bricks are neither too wet nor too dry, but just moist enough to obtain the proper adhesion of the mortar, too much moisture in the brick preventing suction, and too little absorbing the water in the mortar too rapidly; but our Master Mason is in this case an experienced man and all goes smoothly. Once the walls are up to the line of the street another man takes temporary charge.

CARPENTER WORK.

Ranking in importance with the brick work comes the carpenter work, in this case carried out under the direction and control of C. Schutt, of 13 Shotwell street, an experienced mechanic who has contributed his full share towards the successful completion of the building, and who takes a just pride in the work-man-like manner in which his men turn out their work.

Mr. Schutt has well earned the respect to which his many good qualities entitles him, by his care and attention to all work entrusted to his supervision, and he has as a necessary consequence always been able to keep busy in spite of any hard times. He is at present engaged in fitting up the elaborate and elegant interior of the Oberon, which the public have the pleasure of inspecting.

PLUMBING WORK.

The next trade on the long list is that of the plumber, combining the two traits of utility and beauty; filling the walls and floors of the building with a complicated net work of pipes for supply water and gas throughout the building and conducting the waste from the building—and beautifying the utilities with tiling and toilet fixtures such as were never dreamed of by the ancients. H. Williamson of 413 Sutter street, was chosen to do this work, and no one is more competent than he to carry out this particular work, his practical experience having been acquired by years of hard persistent work. He has at his command a staff of skilled assistants who from long familiarity with the best class of work are able to execute Mr. Williamson's orders to do the work as it should be done.

SHEET METAL AND CORNICE WORK.

The sheet metal and cornice work was performed by W. Hite of 224–226 Mission street, in a manner that commends itself to the observer for the neatness and finish, adding to the attractive appearance of the building at the same time it protects it from the elements.

PLASTERING WORK.

Mr. W. C. Watson of 40 New Montgomery street, did the plastering.

DECORATION WORK.

In all the various industries that have thus far been described, usefulness has entered largely into the results accomplished. Yet in our modern life we are learning more and more of the refining influences of beauty in form and

color and the building on which so much thought and care and time and money has been expended yet lacks the finishing touches.

But here comes in our decorator Mr. E. A. Otto of room 81 St. Ann's Building, who gives completeness to whole by copying the splendors of Aladdin's palace for the enjoyment of the patrons of this modern counterpart in the city by the Golden Gate which is rapidly becoming a Metropolis second to none, where art, science and industry will flourish, growing with the needs of its people, learning by its own and its neighbors experience to solve the complicated questions of modern society, till work is justly apportioned to all, and its results as justly divided by all.

ART GLASS.

The beautiful Art Glass in Ladies and Gents Cafe was made and furnished by the well known California Art Glass Works, 103–105 Mission street. The interior finish in the ladies department beidg in the Rococco style, the windows and ceiling light were made in glass to harmonize, while the gents department is in the German Renaissance to conform with decoration of the same. It is unnecessary for us to eulogize the product of the firm mentioned above, as this work again proves that their reputation for first-class work is well earned.

HEATING.

The heating of this entire building is accomplished by a low pressure steam plant, being installed in the building by J. G. Grannis & Co., the well known firm of heating and ventilating engineers, 544 Mission street, and consists of some one hundred radiators and one horizontal sectional steam boiler manufactured by The Novelty Iron Company of Canton, Ohio, with all of the latest automatic improvements and with the complete and scientifically arranged pipe system this plant is a perfect success and but another evidence of the firms great ability in their special line.

VENTILATION.

The ventilation of the first floor and basement is done by the well known method of exhausting the air. Galvanized sheet iron pipes are run from the various rooms and corridors to the light well over the kitchen, where they are connected to one large pipe, 24" diameter, which extends 10 ft. above the roof. The exhausting fan, which is of the windmill or disc pattern, is placed on top of this large pipe and connected to an electric motor, placed on a platform on the roof and housed to keep off the rain. The rheostat for starting the motor is placed in the kitchen, thus giving contro of the fan and motor on the roof from the first floor.

The fan revolves at a speed of 400 revolutions per minute and exhausts 10,000 cubic feet of air per minute. This changes the air in the Gentlemen's Cafe, Ladies Cafe, Banquet Hall and Corridor four times an hour. In the kitchen the air is changed every five minutes, thus keeping the building free from smoke and smell from the kitchen. This method of ventilating has been placed in several cafes and restaurants in San Francisco with uniform success.

This work is being done by the George H. Tay Co., of 610–620 Battery street.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

Consideration in Building Contract.—A building contractor having defaulted before completion of the work, and having permitted liens to accrue against the property in violation of his bond, the contract was assigned to his sureties, and the balance of the price paid to them, on their agreement to finish the work and discharge the liens to an amount not to exceed the amount of the bond plus the amount paid them on the contract. The court held that such agreement was valid and was supported by a sufficient consideration.

McHenry v. Brown, Supreme Ct. Minn., 88 Northwestern Rep. 847.

Liquidated Damages and Penalties.—Where a contractor binds himself in a fixed sum for the performance of the contract, without stating whether such sum is intended as a penalty or as liquidated damages, and without regard to the magnitude or the number of breaches that may occur, or the amount of damages that may issue, and the contract is such that it may be partially performed and partially violated, the sum as fixed is a penalty.

City of El Rene v. Cullinane, Supreme Ct. Okl., 46 Pacific Reporter, 510.

When Contractor is not Liable.—A workman on a building, who fell and was injured by reason of stepping upon a joist which had just been sawn nearly through by another workman, who had momentarily left it, cannot recover from his employer for such injury, on the ground that he should have been notified of the danger.

McCann v. Kennedy, Sup. Ct. Mass., 44 N. E. Reporter, 1055.

What is not Notice to Owner.—The fact that a subcontractor is working on a house does not constitute notice to the owner not to pay the contractor, under the law entitling a subcontractor to lien upon notice to the owner.

Clark v. Edwards, Supreme Ct. N. C., 25 S. E. Reporter, 794.

Negligence in Building Operations.—One who extends an excavation on his lot into the sidewalk of a public street, without properly guarding same or taking any means to warn the public of the danger, is liable for injury to a passer-by who falls into the pit while in the exercise of ordinary care.

Berchers v. Calvin, Ct. Civ. App. Tex., 37 S. W. Rep. 178.

Liability on Contractors' Bond.—Where a building contract, based on plans and specifications made a part thereof, provided that the contractor should make any alterations or additions required by the owner, the price to be subject to addition or deduction for same, as might be agreed upon, the sureties on the contractor's bond cannot defend against liability because the owner in completing the building after its abandonment by the contractor, as was authorized by the contract, deviated from the specifications, nor because changes were made before the abandonment with the assent of the contractor.

De Mattes v. Jordan, Supreme Ct. Washington, 40 Pacific Rep. 402.

BUSINESS MOSAICS.

The John Douglas Co of Cincinnati, Chicago, Philadelphia and San Francisco are the manufacturers of an absolutely noiseless tank for water closets, as well of a superior quality of seats and crockery in this line of goods. Their show room, 208 Ellis street, San Francisco, under the management of Edward Douglas, is well worth a visit from those interested in building.

Poet to editor—I send you a poem, "Why Do I Live?" Please answer. Editor—Because you send your poem by mail.—*Texas Shiftings.*

Cabot's Anti-Pyre, a wonderfully cheap and effective fire-proof paint for interior work, is being handled in this city by Mr. Charles J. Waterhouse, 640 Mission street, general agent for the Cabot Specialties. Used on the interior wood work of factories, warehouses, car-sheds, work-rooms and all places subject to fire risk, it makes the wood non-inflammable, greatly increases the light by the reflecting power of its brilliant white, and is cheaper in the end than whitewash.

"I have cured Bliggins of his horrible superstition at last," the philanthropist exclaimed. "How did you manage it?" "I offered to lend him $13."—*Washington Starr.*

San Francisco Lumber Co., wholesale and retail dealers, foot of Third street, with yards also at Channel St., bet. 4th and 5th streets, is a good place to buy lumber. Uptown office for orders, 405 Montgomery street, J. N. Curtis, manager.

Parson to youngster fishing on Sunday—My boy, I'm surprised to find you here. Youngster innocently—Do you know some other place where they bite better?—*Up-to-Date.*

Stevens' Patent Chimney, endorsed by architects and builders and approved by the fire wardens is advertised on page iii of this journal; every thing from chimney tops to flower pots can be obtained from F. M. Stevens cor. Larkin and Market street, San Francisco.

She—You wife reminds me a great deal of my sister who is in Australia. He—She reminds me a great deal of her first husband, who is Lord knows where.—*Pick-me-up.*

We doubt, if you spend ten thousand dollars for a bath, as it is said one of the Van Ness avenue residences is about to be emblished with, you can have a better bath than can be obtained by applying to S. M. James for one of his Imperial Porcelain Roll Rim Bath Tubs—manufactured by The J. L. Mott Iron Works, see cut on page v of this journal—call at room 27 Flood Building and be convinced of the truth of this assertion.

She—Did you tell Fibs of our engagement? He—Yes. She (aggrieved)—You promised that you would say nothing about it. He—It's perfectly safe with Fibs; no one ever believes him.—*Washington Times.*

Keathinge & Leonard are doing business at their new office in the Hobart Building, 532 Market street, everything in the way of cement work, where twisted iron is required, is right in their line. Work by this firm can be depended upon as being just what is represented.

She—You should see my swell fellow, Fanny. Fanny (enviously)—Your never had a swell fellow. She—Yes I have, he's very swell, he's got the dropsy.

The Pacific American Decorating Company, manufacture stained and art glass—this offers a good opportunity to have your house decorated with landscapes, marine views, to say nothing of having your favorite dog and horse reproduced in your study window—26 O'Farrell street, room 3; 19 Fremont street and 1213 and 1215 Howard street are the places to go if you want the work done.

"The duke's marriage to the American was a bitter pill for his family to swallow." "That is the way with medicine for improvished blood."—*Detroit Tribune.*

Bradley Bros. manufacture a cement tray such as every good house wife wants to have, it is of the best Portland cement and guaranteed not to leak, crack or sweat. Office and factory 53–57 Tehama street.

Geo. Rischmuller, 320 Nineteenth St., San Francisco, make the door opener and closer that answers the purpose to perfection. See advertisement on page iv of this journal where its claim of being just what you want is fully explained.

CITY BUILDING NEWS.

Bartlett near 22d. Two-story frame; owner, John J. Janssen; architects, Martens & Coffey; contractor, J. Bucker; signed, Jan. 29; filed, Jan. 30; cost $3000.

Brannan near 7th. Frame building for barn; owner, H. P. Smith; contractors, Miller & Fredricksen; cost $1725.

Bush near Mason. Three-story frame; owner, Harris Samuels; architect, C. A. Meussdorffer; contractors, A. Caccia and John Peeavich; signed, Feb. 10; filed, Feb. 11; cost $5710.

Dupont near Vallejo. Excavation, etc., for two-story brick; owners, Maccono & Rosso; architect, Frank S. Van Trees; contractor, J. Byron; cost $1450.

Dupont street. Two-story brick building and basement; owner, Isidore Merle; architect, Frank S. Van Trees; contractors, Maccono & Rosso; signed, Jan. Jan. 23; filed, Jan. 24; cost $2695.

Fell near Ashbury. Two-story frame; owner, Mrs. Bertha Bamberger; architects, Shea & Shea; contractor, J. W. Coburn; signed, Feb. 1; filed, Feb. 5; cost $4940.

Fillmore near Filbert. One-story brick; owner, Mary McCarty; architects, Shea & Shea; contractor, Neil Mallov; signed, Jan. 19; filed, Jan. 22; cost $2275.

Geary and Stockton. Work on six-story brick, flooring, etc.; owner, Spring Valley Water Works; architect, Clinton Day; contractor, S. H. Kent; signed, Jan. 22; filed, Feb. 8; cost, $8029. The same contractor, for work on 3rd, 4th and 4th stories; cost $28,411.50. Plumbing, etc.; contractor, Ickelheimer & Bro.; cost $4800. All work above 2d story, contractor, S. H. Kent; cost $12,397.

Geary near Powell. Concrete and artificial stone for five-story brick; owner, A. Aronson; architect, C. R. Wilson; contractor, J. Leonard; signed, Dec. 26; filed, Jan. 22; cost $8750. Cast iron work; contractor, The Alton Iron Works; cost $4000. Wrough iron work and steel beams; contractor, Judson Mfg. Co.; cost $3750.

Geary and Williams. Excavation, brick and iron work for four-story brick; owner, Grace Armont; architect, C. R. Wilson; contractor, Robert Boyd; signed, Jan. 25; filed, Jan. 27; cost $4688. Plumbing; contractors, Burwick & Spinks; cost $1200. Tin work, etc., T. J. Guilfoy; cost $1194.

Geary and Williams. Carpenter and stair work for four-story brick; owner, Grace Armont; architect, C. R. Wilson; contractors, Hawkins & Lindsey; signed, Jan. 28; filed, Jan. 29; cost $3500.

Green near Leavenworth. One-story frame; owner, A. Trueworthy; architect, M. G. Bugbee; contractor, P. J. Brennan; signed, Jan. 25; filed, Jan. 26; cost $988.

Hartford street. One-story frame; owner, G. F. Vella; contractor, John Flaherty; signed, June 22; filed, Jan. 23; cost $1380.

Hayes near Scott. To build; owner, F. W. Keuerleber; contractor, J. J. Mausen; signed, Feb. 5; filed, Feb. 9; cost $3115.

Howard, near 8th. Three-story brick; owner, M. Numan; contractor, for mason work, J. Hagavan. Galvanized iron work; contractor, J. Guilfoy; cost $30,000.

Hyde near Golden Gate Ave. To build; owner, G. W. Rook; architects, Townsend & Wyneken; contractors, Holm & Shelbley; signed, Jan. 30; filed, Jan. 30; cost $1530.

Lot 13 block 47 Sunnyside. Two-story frame; owner, Ann Towns; architect, H. D. Michell; contractors, John Barrett & D. McGrath; signed, Jan. 25; filed, Jan. 27; cost $1895.

Lyon near Grove. To build; owner, H. W. Stokes; contractors, Bailey & Muller; signed, Jan. 13; filed, Jan 30; cost $2500.

Market and Third. Interior tile finish, etc.; owner, Claus Spreckels; architects Reid Bros.; contractors, Gladding, McBean & Co.; signed, Jan. 7; filed, Jan. 25; cost $17,115.

Market and Third. Concrete flooring, metal lath ceiling; owner, Claus Spreckels; architects, Reid Bros.; contractors, Gray Bros.; signed, Jan. 6; filed, Jan. 23; cost $16,715.

Market and Third. Rough carpenter work; owner, Claus Spreckels; architects, Reid Bros.; contractors, Thomas Day & Son; signed, Jan. 23; filed, Feb. 1; cost $5550.

Masonic Ave. near Frederick. Two-story frame; owner, Wm. T. Martin; architects, Shea & Shea; contractor, J. A. M. Donald; signed, Feb. 10; filed, Feb. 12; cost $2338.

Masonic Ave. near Frederick. To build; owner, Carl Griese and wife; architect, Carl Griese; contractor, A. G. Johnson; signed, Feb. 9; filed, Feb. 10; cost $1275.

Masonic Ave. near Waller. Two-story frame; owner, Lyman D. Foster; architect, W. H. Lillie; contractor, Isaac Penny; filed, Jan. 20; cost $2545.

McAllister near Devisadero. Two-story frame; owner, Evlyn G. Graney; architect, Phillip Rive; signed, Jan. 28; filed, Feb. 18; cost $5250.

Montgomery dear Sutter. Alterations and additions; owner, Alexander D. Keyes; architects, Shea & Shea; contractor, P. Griffin; signed, Jan. 18; filed, Jan. 20; cost $4497.

Nineteenth and Minnesoto. Three-story frame; owner, P. Cronin; architect, M. J. Welsh; contractor, C. J. Antwiler; signed, Jan. 26; filed, Jan. 26; cost $2415.

Oak near Ashbury. To build; owner, Leon J. Hirth; architect, E. Depierre; contractors, Maccono & Rosse; signed, Jan. 20; filed, Feb. 1; cost $3400.

Pierce and Greenwich. Two-story frame; owner, F. G. Eichorst; architect, C. A. Meussdsrffer; contractors, Stevens & Foster; signed, Feb. 1; filed, Feb. 4; cost $1949.

Sacramento and Scott. Two-story brick; owners, F. W. and Sarah Marion; architect, C. A. Robertson; contractor, Wm. Bell; filed, Feb. 1; cost $9000.

Sacramento neas Buchanan. Alterations and additions; owner, Phoebe Lowenthal; architects, Salfield & Kohlberg; contractors, C. D. Dean & Co.; signed, Feb. 9; filed, Feb. 9; cost $1415.

Second Ave. near Lake. Cottage; owner, Richards Trevers; architect, Richard Trevers; contractor, W. P. Kenney; cost $1045.

Sixth Ave. near California. Cottage; owner, Margaret Whittman; contractor, L. C. Bergren; signed, Jan. 19; filed, Jan. 26; cost $1358.25.

Seventeenth near Sanchez. To build; owner, Richard O'Connor; contractor, T. C. Cochran; cost $2775.

Sutter and Hyde. Wrought iron grill work for six-story brick; owner, Dr. Julius Rosenstern; architects, Salfield & Kohlberg; contractor, Richard Lutze; signed, Dec. 24; filed, Jan. 28; cost $1848.

Sutter near Larkin. Three-story frame, carpenter work; owner, Dr. Henry Kreutzmann; architect, Oscar Haupt; contractor, Henry Jacks; signed, Jan. 20; filed, Jan. 30; cost $7508. Painting; contractor, J. F. Sullivan; cost $775. Plumbing; contractor, E. J. Duffy; cost $920. Plumbing; contractor, E. J. Duffey; cost $920. Electric work; contractor, California Electric Work; cost $236.

Twenty-first near Folsom. Two-story frame; owner, H. Bullwinkle; architect, Henry Geilfuss; contractors, Horstmeyer; signed, Feb. 3; filed, Feb. 4; cost $2700.

Twenty-fourth near Noe. Additions; owner, Anne Drolette; contractors, A. De Lair and D. T. Francoeur; cost $1400.

Twenty-seventh near Dolores. Cottage; owner, Alfred Ross; architect, C. M. Rousseau; signed, Feb. 4; filed, Feb. 5; cost $1400.

Waller and Schrader. Cottage; owner, Mrs. Carrie Driscoll; architect, Wm. Koenig; contractor, Ira W. Coburn; signed, Jan. 21; filed, Jan. 22; cost $1500.

THE San Francisco *Call* has lately been stirring up the public bodies of this city to take united action in protesting against further delays in beginning work on a new post office building for this city that was authorized by Congress over a decade ago. We sincerely commiserate our daily press if they really think that any efforts, however herculean, will have any effect in piercing the invulnerable hide of official indifference to the needs of San Francisco, for we are morally certain that they will have but their labor for their pains. True, plans have been prepared for such a building. In fact the office of the Supervising Architect has been preparing plans for several years; the ones now under consideration being the third set we believe, and apparently we are no nearer a satisfactory solution than at first. Several experts and engineers have already examined and reported on the site selected with special reference to its suitability to sustain a modern brick structure. We notice in the last official report of the Supervising Architect, however, that "The United States Engineer Corps has been requested to submit further information in regard to foundations, and it is expected that this office will be fully advised in regard thereto at an early day." The report does not specify any grounds on which to base its expectations for an *early* report, and in the light of past experience, we confess to some degree of scepticism in regard to the expeditious methods of public officials. But if our generation no longer hopes or expects to see the work begun, future generations will have the pleasures of anticipating the day when ground will be broken for the new building.

The following information as to the acts of Congress authorizing the Post-Office may be of interest to our readers:

An Act of Congress of March 3d, 1887, appropriated for cost of site and building, $350,000.

An Act dated January 21, 1889 extended the limit of cost of site for building to $800,000.

Other Acts were passed modifying the cost of the site and building and an Act of March 3, 1893, extended the limit of cost of building exclusive of site to $2,500,000.

There has been appropriated to date $1,300,000.

Of this amount there has been expended on site and incidental expenses $1,090,268.

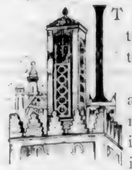
Leaving the amount actually available for beginning work at this date $209,732.

WE REGRET to have to chronical the defeat of a proposed law introduced in the present Legislature, having for its object the regulation of the practice of the profession of architecture in this state.

The bill was reported adversely by the Committee to which it has been referred on the ground that the proposed measure was "Unconstitutional".

The bill was identical with one that the Legislative committee of the previous session reported favorably, and which passed the Assembly to be defeated in the Senate.

Query—How can a bill that is constitutional one session, be unconstitutional the following session, the same constitution governing both sessions?



IT IS disheartening at the end of the Nineteenth century to find such a paragraph as this in the paper:

"Manager Lewis of the Manufacturers' and Producers' Association went to Sacramento yesterday for the purpose of having introduced in the Legislature a bill abolishing machinery in the State prisons after December 31, 1898. This is pursuant to an action taken by the association last Tuesday."

Over one-half century ago there were riots in the old countries against machinery—during which much machinery was destroyed—but the march of progress cannot be stopped by riots and machinery has been a factor in production ever since and will be still more so.

And surely if we can raise our criminals by giving them honest labor to do and labor that they can see is utilized to the best advantage by the use of machinery, this is a good thing. And is it not better to make the criminal classes who are born so that idleness encourages their propensities work. Surely it must be better to give them work, than to put the honest citizen, who can utilize his leisure in devising schemes for the benefit of the people, to hard labor Let the criminals labor, to whom it is a blessing, and let the honest man reap the benefit. The more machinery we have the better, for the more leisure we thereby get for intellectual and recreative occupation.

It is a mistake to suppose that man was created for hard labor—to earn one's bread by the sweat of one's brow was a truism in the primitive days of no machinery but now the truism of those days is the untruth of these latter days, and there needs no eight or ten hours work day.

The crass ignorance of economics exhibited by our most respected citizens is wonderful. Here in San Francisco we have men supposed to be charitable offering work on a boulevard for the improvement of the city and the increasing of the value of its real estate at one dollar for a day of not less than eight hours. This is absurd. Cannot they see that in these days when machinery does almost all the work that is to be done, this is altogether too long for any man to work at hard labor except he be a criminal, to whom it may be all right as a tonic.

IT APPEARS from a late number of the *Engineering News*, that discrimination is made by the Board of Examiners who pass upon the structural part of buildings in New York, against Concrete for Fireproof arches in favor of Hollow Tile and other material. The makers of concrete combined with iron such as the Ransome Patents, the Roebling Sons & Co. and the Expanded Metal System makes are hereby done an injustice; as experiments go to show that concrete properly fortified is quite as strong and fireproof as any other material used for flooring arches.

We will not go into the question of relative strength further, but that apart, it appears the Board of Examiners refuse to give any reason for rejecting this material—an arbitary action of a public body which is unseemly. Looking at the construction of this tribunal we find it composed of:

Superintendent Building Department, Chairman; Napoleon Le Brun, from the New York Chapter of the American Institute of Architects; two members from the Mechanics' and Traders' Exchange; one from the Real Estate Exchange, the Architectural Iron Association, the Builders' Association, the Underwriters' Association and the Chief of the Fire Department.

These have irresponsible power and in this case appear to have exceeded those powers; but there seems to be no tribunal that is competent to decide how far those powers shall extend. The matters upon which the Board have to decide are scientific matters and the connection between technical matters of this kind and trades and Real Estate Exchanges or even the Architectural Iron Association appears to be rather remote, and yet we find two members from the mechanics and Trades Exchange one from the Real Estate Exchange and one from the Architectural Iron Association. In our opinion, an architect selected by the builders (who are the class who come in contact with them most) and civil engineers, would fill the bill in better shape than those mentioned above as unsuitable. It is their business to know about these things and are therefore those likely to know most about them. The Board evidently wants reviewing, and may be looked upon by other cities as a Board whose composition must be avoided.

BILLS OF QUANTITIES AND THEIR RELATION TO BUILDING CONTRACTS.

PAPER READ BY G. ALEXANDER WRIGHT BEFORE THE SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS, FEBRUARY 12, 1897.

MR. PRESIDENT AND GENTLEMEN:—I have been honored with an invitation from your honorable Chapter to say something to-day upon the subject of "Bills of Quantities and their Relation Generally to Building Contracts:"

The field is a wide one, embracing I think, some points of interest to each of us who are in any way identified with estimating the cost of modern buildings.

With your permission, and whilst fully appreciating the importance, or shall I say the absolute necessity for the young architect of to-day as well as for the contractor, to receive some training in estimating *Q's*,* as well as in estimating *cost*, I propose to consider the subject largely from an estimators standpoint.

During my experience—first as an architect, and subsequently as a Q. S.† in fairly active practice—it has fallen to my lot, to have had many opportunities of judging of the value and advantages attending the use of Q's and the effect of the Q. Sy.‡ upon the owner, the contractor, the architect, and incidentally upon the character and quality of the work executed.

I shall endeavor to lay before you some conclusions I have arrived at, and if my efforts simply have the effect of fostering the growing desire for some improvement in the estimating methods of to-day; or of promoting a friendly interchange of thoughts upon the subject, our time will not, I think, have been unprofitably spent.

By way of introduction I may be allowed to say that some six years ago I was privileged to be present at a meeting of this honorable Chapter and in the course of a short address upon that occasion; I made some observations regarding the system of taking bids upon surveyors Q's and I afterwards brought the same subject before the notice of the Builders' Association, then on Pine street.

Some attempt had already been made by one or two local architects, and also by a Q. S. who had preceeded me—to create some interest in this subject—but little progress however had been made—and I found but few who were acquainted with even the first principles of the "system", and I was not slow to realize how unreasonable it was to expect gentlemen to look kindly upon an estimating system, which to them, as a body, was at that time, something new.

In additions to this, I was then myself somewhat handicapped by want of acquaintance with local methods. To-day however gentlemen, the conditions are changed.

On the one hand, a desire for some improvement in the manner of estimating for work, does occasionally manifest itself and on the other hand, I also, have gained some experience, having made up estimates—some millions of dollars worth probably—for contractors and others in this city, and so to-day gentlemen, I say the conditions existing when I addressed you before, are somewhat changed, and I am free to admit, and I do so most willingly, that an elaborated system of Quantities, would scarcely be adapted, certainly, for some time to come to our San Francisco requirements. *But*, (and I say this with every respect for the views of gentlemen who may not altogether agree with me.) *But* I am equally certain that there is a great dead of room for improvement in our estimating methods of to-day. They are largely primitive and *unreliable*—rule of thumb often preyails, whilst the element of guess-work is not entirely unknown—all of which is, I submit contrary to, and out of keeping with that spirit of advancement which you as architects, have been advocating so long, and which you are happily, still promoting, in the matter of improved design and construction.

Now let us proceed to consider the effects of the Q. S. Let us analyze its application to a large building, say of brick, stone and steel construction.

As the owners agent it would under the Q. Sy. devolve upon the architect to choose a S. as soon as the owners instructions to obtain bids were received. He must not be appointed by either of the financially interested parties, the owner or the contractor.

When wisely selected he should occupy an independent, disinterested position, possessing of course the necessary technical and practical ability, and having the confidence of those, liable to be effected by his Q's.

He should never be in the regular employ of any one person, his services being engaged by "Architects," on behalf of their clients and *only* as occasion requires, and for the specific work and purpose indicated.

It has recently been suggested to me that a dishonest surveyor might favor, or in some way give an advantage to some particular contractor. I deal with this point first as it seems uppermost in the minds of some, indeed it seems to be about their only objection to such a system—that dread of trickery.

Gentlemen—The only answer it is possible to give is this: No surveyor possessing any self respect, and in his natural senses, would jeopardize his living, and invite professional ruin, by placing himself at the mercy of an unscrupulous contractor; *for*, would it not be only such, who would attempt to benefit (even if such a thing were possible) for "detection" would be the easiest thing possible by such means?

But to return—The surveyor having been selected, the drawings, specifications and conditions of contract, are handed to him by the architect. From these he prepares in his own private office, a complete schedule or B of Q's containing a detailed, itemized, and classified list of every item of labor and material required in the building, everything in fact which has a money value, however small, and this is done, whether everything is described with extreme minuteness in the specification, or *not*.

It is well known that occasionally some little oversight, on the part of an architect's clerk, *will creep in somewhere*, (however careful he may be) and is it not a fact that a certain class of contractors, are apt to distort trivial occurrences of this nature into an excuse to try for some extra allowance or concession thereby. Now all such points as I have reference to, would not escape the surveyor, that is a part of his business; to see that no possible opportunity for misunderstanding shall exist, if it does, the attention of the architect is drawn to the matter and the necessary adjustment is made *before the contractor ever sees the drawings*.

The Q's being completed, printed copies are sent to those contractors invited to bid; the drawings and other documents are returned to the architect and the surveyor's duties are at and *end*.

His business is solely to calculate Q's, fairly and honestly between owner and contractor. He has not the slightest further interest in the job (beyond receiving his fee) cares not how much it costs, nor who gets the contract, nor is he interested in what kind of materials are used, where they are *ordered*, or what they *cost*. Such things are outside his province entirely. He devotes himself exclusively to the accurate computations of "Quantities"

Although not always done, I advocated making the Bill of Quantities the basis of and part of the contract, in other words, a certain definite quantity of work for a certain fixed sum of money. The specifications too, need not be so voluminous as they sometimes are. The custom is for the lowest bidder to deposit with the architect, prior to the acceptance of a bid, a copy of his original figures in *ink* and a spare blank copy of the Q's is usually reserved for this purpose free of expense. The architect satisfies himself that this copy has been filled up and totalled in proper form, and

BILLS OF QUANTITIES AND THEIR RELATION TO BUILDING CONTRACTS.

PAPER READ BY G. ALEXANDER WRIGHT BEFORE THE SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS, FEBRUARY 12, 1897.

MR. PRESIDENT AND GENTLEMEN:—I have been honored with an invitation from your honorable Chapter to say something to-day upon the subject of "Bills of Quantities and their Relation Generally to Building Contracts:"

The field is a wide one, embracing I think, some points of interest to each of us who are in any way identified with estimating the cost of modern buildings.

With your permission, and whilst fully appreciating the importance, or shall I say the absolute necessity for the

young architect of to-day as well as for the contractor, to receive some training in estimating *Q's*,* as well as in estimating *cost*, I propose to consider the subject largely from an estimators standpoint.

During my experience—first as an architect, and subsequently as a Q. S.† in fairly active practice—it has fallen to my lot, to have had many opportunities of judging of the value and advantages attending the use of Q's and the effect of the Q. Sy.‡ upon the owner, the contractor, the architect, and incidentally upon the character and quality of the work executed.

I shall endeavor to lay before you some conclusions I have arrived at, and if my efforts simply have the effect of fostering the growing desire for some improvement in the estimating methods of to-day, or of promoting a friendly interchange of thoughts upon the subject, our time will not, I think, have been unprofitably spent.

By way of introduction I may be allowed to say that some six years ago I was privileged to be present at a meeting of this honorable Chapter and in the course of a short address upon that occasion; I made some observations regarding the system of taking bids upon surveyors Q's and I afterwards brought the same subject before the notice of the Builders' Association, then on Pine street.

Some attempt had already been made by one or two local architects, and also by a Q. S. who had preceeded me—to create some interest in this subject—but little progress however had been made—and I found but few who were acquainted with even the first principles of the "system", and I was not slow to realize how unreasonable it was to expect gentlemen to look kindly upon an estimating system, which to them, as a body, was at that time, something new.

In additions to this, I was then myself somewhat handicapped by want of acquaintance with local methods. To-day however gentlemen, the conditions are changed.

On the one hand, a desire for some improvement in the manner of estimating for work, does occasionally manifest itself and on the other hand, I also, have gained some experience, having made up estimates—some millions of dollars worth probably—for contractors and others in this city, and so to-day gentlemen, I say the conditions existing when I addressed you before, are somewhat changed, and I am free to admit, and I do so most willingly, that an elaborated system of Quantities, would scarcely be adapted, certainly, for some time to come to our San Francisco requirements. *But*, (and I say this with every respect for the views of gentlemen who may not altogether agree with me.) *But* I am equally certain that there is a great dead of room for improvement in our estimating methods of to-day. They are largely primitive and *unreliable*—rule of thumb often prevails, whilst the element of guess-work is not entirely unknown—all of which is, I submit contrary to, and out of keeping with that spirit of advancement which you as architects, have been advocating so long, and which you are happily, still promoting, in the matter of improved design and construction.

Now let us proceed to consider the effects of the Q. S. Let us analyze its application to a large building, say of brick, stone and steel construction.

As the owners agent it would under the Q. Sy. devolve upon the architect to choose a S. as soon as the owners instructions to obtain bids were received. He must not be appointed by either of the financially interested parties, the owner or the contractor.

When wisely selected he should occupy an independent, disinterested position, possessing of course the necessary technical and practical ability, and having the confidence of those, liable to be effected by his Q's.

He should never be in the regular employ of any one person, his services being engaged by "Architects," on behalf of their clients and *only* as occasion requires, and for the specific work and purpose indicated.

It has recently been suggested to me that a dishonest surveyor might favor, or in some way give an advantage to some particular contractor. I deal with this point first as it seems uppermost in the minds of some, indeed it seems to be about their only objection to such a system—that dread of trickery.

Gentlemen—The only answer it is possible to give is this: No surveyor possessing any self respect, and in his natural senses, would jeopardize his living, and invite professional ruin, by placing himself at the mercy of an unscrupulous contractor; *for*, would it not be only such, who would attempt to benefit (even if such a thing were possible) for "detection" would be the easiest thing possible by such means?

But to return—The surveyor having been selected, the drawings, specifications and conditions of contract, are handed to him by the architect. From these he prepares in his own private office, a complete schedule or B of Q's containing a detailed, itemized, and classified list of every item of labor and material required in the building, everything in fact which has a money value, however small, and this is done, whether everything is described with extreme minuteness in the specification, or *not*.

It is well known that occasionally some little oversight, on the part of an architect's clerk, *will creep in somewhere*, (however careful he may be) and is it not a fact that a certain class of contractors, are apt to distort trivial occurrences of this nature into an excuse to try for some extra allowance or concession thereby. Now all such points as I have reference to, would not escape the surveyor, that is a part of his business; to see that no possible opportunity for misunderstanding shall exist, if it does, the attention of the architect is drawn to the matter and the necessary adjustment is made *before the contractor ever sees the drawings*.

The Q's being completed, printed copies are sent to those contractors invited to bid; the drawings and other documents are returned to the architect and the surveyor's duties are at and *end*.

His business is solely to calculate Q's, fairly and honestly between owner and contractor. He has not the slightest further interest in the job (beyond receiving his fee) cares not how much it costs, nor who gets the contract, nor is he interested in what kind of materials are used, where they are *ordered*, or what they *cost*. Such things are outside his province entirely. He devotes himself exclusively to the accurate computations of "Quantities"

Although not always done, I advocated making the Bill of Quantities the basis of and part of the contract, in other words, a certain definite quantity of work for a certain fixed sum of money. The specifications too, need not be so voluminous as they sometimes are. The custom is for the lowest bidder to deposit with the architect, prior to the acceptance of a bid, a copy of his original figures in *ink* and a spare blank copy of the Q's is usually reserved for this purpose free of expense. The architect satisfies himself that this copy has been filled up and totalled in proper form, and

* Quantities.
† Quantity Surveyor.
‡ Quantity System.

and that the sum total corresponds with the contract amount, the document is then sealed up in the presence of the contractor and filed away for safe keeping, to the importance of which I shall refer to later on.

The unsuccessful bidders retain their copies of the Q's, and being priced in detail, they are frequently of use, as a means of reference, and form interesting data to the contractor when determining his percentage of profits on future bids.

Surveyor's Q's are sufficiently explicit, as to make it unnecessary for the bidders to closely examine the drawings and specifications whilst bidding, this is a saving of time to *them*, and architects' time would not be occupied in making explanations, and answering questions to bidders. The quantities would explain, in black and white, everything that is right and proper for the bidders to know.

Occasionally we hear of a lowest bidder, wishing to withdraw his bid, or endeavoring to get the amount of it increased, on the grounds of having made a "mistake", forgotten to include his painters bid or his glass or some other thing, but with the Q. S. such a thing would be an impossibility; for everything would be there, in detail. If "money" mistakes were alleged, than by a reference to the priced Q's, the architect could immediately see whether the mistake was a genuine one or not. Gentlemenn, I don't think you would ever hear of a mistake in a bid under that system.

I am sometimes asked, well, what *is* a proper B of Q as used under the Q. S.? In localities where this method of estimating prevails, a B of Q is expected to be what some owners think an *architect* ought to be. "Everything under the sun," and this is just what a B of Q should be, in relation to the contract, a veritable "enquire within for everything." I cannot do better perhaps than quote very briefly for a few moments from an article of mine which appeared recently in the *American Architect* of Boston:

The document should be a *printed* list so that every copy should be an exact counterpart of each other, the same as blue prints are of drawings. It should contain as I say every item of work in the building, however small. On the title page should appear the name or description of the building, the owners and architects names and addresses, place, date and hour for receiving bids, date for completion, and under the heading of preliminary, the penalty for non-completion, conditions of payment, particulars as to sureties, certified checks, and so forth, and the bill should bear the endorsement of the surveyor who prepared it.

Again, when practising as a Q. S. I found it a good plan to commence with such items as cannot be measured in the usual sense, but for which some allowance should be made for example, plant, foremon, superintendent's office, drainage, insurance, lighting, watchman, interest or retention money, pumping or keeping foundation dry; maintenance, accidents to workmen, water, temporary plumbing, strike, contingencies. In some estimates I have found it necessary to consider *all* these questions, and it is better to treat them altogether, under one heading.

The items proper, begin with "excavator," each class of work having a different value being "segregated," as for example: surface digging, foundation trenches above and below five feet deep, cellars, circular digging, forming slopes, each should, having different values, be given separately, state if carried out in baskets or wheeled, or hauled by team and how far. The same principle applies to engineering work, such as blasting, mud and tide work and such items.

Under "drainage" the quantities of all the different pipes, their sizes and depths, including number of bends, junctions, diminishing pieces, hoppers, etc., method of forming the joints of the drains and so on, should be stated.

The brickwork bill should begin with a brief but clear description of all the bricds used—facing, common, fire or otherwise, the kind of pointing to joints, proportions of mortar, brand of cement. Then might come the "number" of bricks, keeping the different thicknesses of walls separate.

Here I would like to observe that there seems to me to be some need for a uniform standard of measurement for brickwork—cost cannot be *accurately* estimated, by simply saying there are so many bricks in a building, for the reason that the labor on brickwork differs a good deal in proportion to the thickness of the walls, and whether pointed or not, a wide foundation or basement wall starting say ten feet below ground, costs less per M than a chimney breast and chimney rising perhaps seventy feet high or more. On the whole I think it is better to give the number of square feet or yards of wall surface, stating how may bricks thick, as half brick thick, one brick thick, two and one-half brick thick and so on, stating if points are left rough, or flat pointed for whitewashing, or cut joints, as the case may be. It is neither wise, nor skillful to strike an average in such cases, and to "lump" the whole thing together at so much a M, for it is the attention to *little* things that tell in estimating. No one thinks much of half a brick, or as we call it, a *bat*, and yet I remember a building I figured, I think it was the City Hall tower, in which a bat, more or less, to the square foot, made a difference of over $3000, in the price of the brick work.

But to return—footings and very thick walls, should be separated from the general walling, also chimneys above, and parts built "in cement" should be so billed and described.

Brick facings—by the square foot these would be given as "extra only" or additional above the price of the common walling. Mouldings, cills and ornamental courses by the lineal foot with these latter I prefer to give all the mitres, etc., internal and external, and returned ends for the reason that when specially molded (as of course they should be in best work) they are more expensive than straight stock of the same kind. The same applies to brick copings, bands, belts, imposts, cornices, etc., etc.

Fair or face arches are given by the square foot, keeping the straight, distinct from the circular. Rough internal arches may be numbered, but the width of opening, rise, thickness and height must be stated.

Numbers of such items as cutting holes, setting grates, safes, boilers, ventilators, etc., with descriptions should appear. In all cases marginal sketches should be given when necessary to illustrate the detail for the contractors information.

A common practice is to commence with all the largest and most expensive items in the materials, and the smallest items in the labors, and here I more particularly refer to the "masons'" bill, though in San Francisco practice, such detail might not perhaps be necessary. We begin with feet cube or rough stone in blocks, each kind of stone being separated, then tons or yards, cube of rubble stone in backings. Lineal items follow, these being stones under 12x12. Small stones are numbered, and described, or sketched. Labor on stone would be in some thing like the following order. Half sawing, plain work, plain work circular, ashlar, pitched, hammered or other facing, all by the square foot. Then we get sunk work as in niches, the same circular.

Next to that is molded work—straight and circular, rubbed and polished work as on marble and granite—both straight and circular, and even circular circular as in spheres and globes, each and every piece of different money value being separated.

In general terms—the same principol applies to mill work, stair work, in fact every part, of each trade is set forth in a similar way—but I will not take up your time with further illustrations.

The bidders price the items in the Q's, and carry the totals of each trade, to the general summary, at the end of the bill and here the bidder finds a space in which to include the Surveyor's fee, or percentage on the sum total.

Upon the contract being let, the better plan, is for the surveyor to be paid upon the architect's certificate, plus of course the out of pocket expense of printing or lithographing the Q's.

It is true that to prepare such Q's as I have referred to calls for more time than individual contractors usually get allowed under the existing method of estimating, but I submit this is of small moment in view of the accuracy and advantages obtained. Three distinct processes are required—1st the taking off or measuring from the drawings, these particulars being inserted in the "dimension" sheets, there *cubed* or *squared* up, etc., as the case may be and these sheets are carefully preserved for reference. 2d The making up of the abstract sheets whereby all similar items are collected, condensed and finally classified. 3rd Writing the bill, which should contain full *descriptions*, and this document is the original of those sent out to the bidders.

The only accurate manner of estimating that I am acquainted with is to systematically measure every part of the building piece by piece—guess at nothing, and take no chances. To do it, may be a little tedious to those not accustomed to such work, but there is no "royal" road—short cut methods are not to be depended upon, cubing or squaring are but approximate guesses, good in their way for certain purposes, but quite unsuited in determining *how much money* an owner is to *pay*, or a builder is to receive for a building.

The system will readily admit of a building being let as a whole, or divided up into contracts one for each separate trade, if necessary.

I have prepared by way of illustration, a few specimen sheets of Q's such as I think would satisfy reasonable requirements in San Francisco for some time to come, and they are here for your inspection—of course in actual practice they would be as I say either printed or lithographed.

Continued in April number.

The Experiment made by Captain W. de W. Abney, C. B., in the Raphael Cartoon Gallery of the South Kensington Museum, London, of using colored glass to intercept the rays of light which act injuriously on pigments is said to be considered quite successful. The colored glass is hardly noticeable, and many people walk through the gallery without being aware of its existence. The system will probably be extended to the skylights of all the picture galleries in which water colors are hung.—*Building News.*

RECOVERY FOR SERVICES PERFORMED BY ARCHITECTS IN PREPARING DRAWINGS, PLANS, ETC.

Evidence of customary charges of architects for similar services competent, although they may be shown to have originated in a rule of compensation established by architects' associations and not binding upon defendant.

Appeal from the Superior Court of San Francisco County. John Hunt, J.

For Appellant, Robert Harrison, Michael Mullany.

For Respondent, A. P. Van Duzer, Walter H. Levy.

Filed January 19, 1897.

IN BANK.

Augustus Laver et al., Appellants vs. A. P. Hotaling, Respondent. San Francisco No. 502.

Plaintiffs are co-partners in the practice of their profession as architects. They sued in this action to recover the alleged reasonable value of services performed, it is claimed, at defendant's request, in the preparation of drawings, plans and specifications for a building defendant had in mind to erect. After verdict, and judgment in plaintiff's favor, the court granted a new trial, on the sole ground specified in its order, that it erred at the trial "in permitting the introduction of evidence of a rule of compensation of architects, established by architects' institutes or associations." The plaintiffs appeal from the order granting a new trial, and contend that if any evidence of a rule of compensation established by architects' institutes or associations was admitted, it was not introduced or offered by them. A careful examination of the record convinces us that this contention is well founded. In order to prove the value of their services the plaintiffs introduced evidence of the customary charges of architects for similar services. The evidence was, of course, entirely competent; just as the current market price is evidence of the value of goods sold.

On cross-examination of plaintiff's witnesses, and on the direct examination of his own witnesses, defendant brought out the fact that the customary rates of charges made by architects originated in, and conforms to, a rule established by an association of architects. But the fact that the customary rate of charges originated in a rule which, as such, was not binding upon the defendant did not render evidence of the actual custom incompetent. If the usual and regular wages of a mechanic are three dollars per day, does such customary rate become any less competent evidence of the value of his services when it is shown to have been first prescribed by a rule of his union? Certainly not. The rule, it is true, is not binding, as a rule upon those who have not made it a part of their contract, and no one is held to have made it a part of his contract unless charged with knowledge of it. But, however ignorant an employer may be of the customary rate of compensation, such customary rate is evidence of value in any suit by his employee upon a *quantum meruit*.

The Superior Court did not err, therefore, in admitting the evidence offered by the plaintiffs, or in refusing to strike it out after the defendants had proved the rule of architects. And certainly the defendant was not entitled to a new trial because of the testimony offered by him.

The instruction of the court to the jury, with reference to this testimony, may have been misleading, but it was not excepted to at the time, nor was it specified as a ground of

the motion for a new trial, and can lend no support to the order.

Other grounds were specified in support of the motion, but none of them are relied upon in the argument of counsel, and we cannot see that they possess any merit.

The order granting a new trial is reversed.

BEATTY, C. J.

We concur:—Van Fleet, J.; Temple, J.; Harrison, J.; Henshaw, J. I dissent:—McFarland, J.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

ON THE HILL, San Francisco, C. A. Meussdorffer, Architect.

COUNTRY RESIDENCE, Linden Bree, Del.

COTTAGE AND PLANS, John J. & T. D. Newsom, Architect.

THE PAPST CAFE.

IN our description of the handsome Pabst Cafe, that appeared in our last issue a mistake crept in which we take the first opportunity to correct. Credit for the sheet metal and cornice work is due to Mr. W. Heidt of 224–226 Mission street.

In making this correction and again calling the attention of the public to this work, we consider we are only doing justice to Mr. Heidt and the care and attention which he gives to all work confided to him.

CORRESPONDENCE

The Editor is not responsible for any opinions of Correspondents.

To the Editor of the California Architect and Building News.

Referring to "Strollers" enquiry in your last issue as to the proportions for treads and risers, there seems to be no "unalterable" rule, within reasonable limits, if the width of tread plus height of riser=18", a fairly easy going staircase is obtained; for example a 6½" riser to a 11¼" tread—but if *this* rule be carried to *extremes* it would of course be possible to so distort the proportions, as to make stairs resemble a step ladder.

Again, if the "rake" or pitch of stairs be made 30° the result is fairly satisfactory. It would appear that the length of a persons step should govern the width of tread, and as this varies with tall and short people, old and young, an "average" length of a persons step might be, say 24.75 inches. Then taking 6¾" as an "average" for a riser, the following formula would give a good result:

24.75"—(6.75x2)=11.25" the width of tread

This being the same, as in the 18" rule already mentioned for tread and riser. For outside entrance steps, it is better to decrease the riser, and increase the tread.

G. ALEXANDER WRIGHT

FROM THE THIRD BIENNIAL REPORT OF STATE MINERALOGIST—STRUCTURAL MATERIAL.

CONTINUED FROM LAST NUMBER.

GRANITE

MADERA COUNTY

Day Quarries—They are 2 miles S. of Raymond, and were thoroughly equipped in 1893, and worked for a time. Are now idle. Day & Sons, of Raymond, owners.

McLennan Quarries—They are 1½ miles SE of Raymond and have been worked steadily during the past three years, employing from 20 to 60 men. The quarry improves as it is opened, both in quality of the stone and in the size of the blocks which may be obtained. Blocks of granite, 25'x25'x10' are available, if they could be handled. A. McLennan of Raymond, owner.

Raymond Granite Quarry—It is 1½ miles E of Raymond, on a spur track of the railroad from Berenda to Raymond. This great quarry has been actively worked for several years, giving employment to a large number of men at the quarries and at the company's yards in San Francisco, where most of the finer stone-dressing is done. After an interval of over two years no considerable impression seems to have been made on this immense, dome-shaped, granite hill. Any noticeable change has been for the better. The great block

ARCHITECT.
97-98 STEVENS' BLDG. S.F.

referred to in our XIIth Report has been proven to be thicker as the front portion has been removed. It averages about 20′ in thickness now, 40′ and more in exposed width, and over 300′ in length; when this has been removed, a similar great concentric mass underlies it. The great advantage in this granite lies in its remarkobly homogeneous texture. A slab 20′ in length, or even more, may be riven from a much larger block by the "feather and plug" system, none of the holes being over 3″ or 4″ deep, and the river surface will be almost a perfect plane. Raymond Granite Co., owner; D. L. Knowles, of Raymond, superintendent.

NEVADA COUNTY

Pine Grove Quarry—It is ½ mile E of Nevada City, and comprises 2½ acres. It consists of the working of large bowlders of a fine-grained, hard granite, suitable for curbing, steps, basses to monuments, etc. One hand-derrick with 40′ boom is used. The output last year was 1,000′ of curbing Two cutters are employed, E. D. Bridges, of Nevada City, owner.

PLACER COUNTY

A large area of granite rock ("grano-diorite" of W Lindgren, of the U. S. G. S.) between Auburn and Roseville stretches northward, more or less disconnected, approximately to Bear River. It is extensively quarried about Rocklin, Loomis, Penryn, and Lincoln, and is used for general building purposes, and occurs in large masses, separated by that which is partially disintegrated. About Rocklin and Lincoln it is uniformly very light colored, and shows too little contrast between polished and rough surface. As the eastern boundry of the region is approched it becomes darker. It is said to resist great crushing force.

Borghese & Silvino's Quarry—It is 2 miles NE of Lincoln. Street-curbing is worked from an outcrop or bowlder. Three men afe employed. C. Borghese of Lincoln, manager.

Brady's Quarry—See our XIIth Report, p. 384. It is near Rocklin. Idle. — Brady of Rocklin, owner.

Burlin & Temdle Quarry—It is a small quarry, 2½ miles NE of Lincoln. It empleys 3 quarrymen, 3 stonecutters, and 2 hand-power derricks. William Burlin of Lincoln, manager.

Burns (Burns & Coffey) Quarry—See our XIIth Report, p 384. It is a small quarry, 3 miles SE of Lincoln. Two steam-power derricks are used, and 3 quarrymen and 2 stonecutters are employed. M. Burns of Lincoln, superintendent.

Calderwood's Quarry—See our XIIth Report, p. 385. It is a small quarry, 1½ miles E of Lincoln. Idle. — Calderwood, of Lincoln, owner.

Carlaw Bros.' Quarry—It is 1¼ miles E of Loomis, in Sec. 10, T. 11 N., R. 7 E., at about 375′ elevation. There are 17 acres in the property, on which is a vast quantity of light gray granite rock, used principally in building and cemetery work. One steam-power derrick is used. The rock is hauled to Loomis in the rough, at a cost of $7 per car, and shipped to Sacramento, where the cutting is done. Six men are employed at the quarry. A. W. Turner, of Loomis, superintendent.

Copp's (Copp & Waters) Quarry—See our XIIth Report, p. 385. It is ½ mile SE of Rocklin, in the NE ¼ Sec. 29, T. 11 N., R. 7 E., at about 240′ elevation. The open cut is about 100′x200′ and 80′ deep. Four steam-power derricks are used. The stone quarried is largely used for vaults, foundations, monuments, and buildings; 10 quarrymen, 5 stone-cutters, and 3 laborers are employed. R. H. Copp, of Rocklin, owner.

Dunn's Quarry—It is in Rocklin, on leased ground, in Sec. 29, T. 11 N., R. 7 E. Two horse-power derricks are used. Three men are employed, cutting curbing. D. Dunn of Rocklin, manager.

Eureka Quarry—See our XIIth Report, p. 386. It is in Rocklin, in the NW ¼ Sec. 29, T. 11 N., R. 7 E. The open cut is 75′x200′ and 70′ deep. Three steam-power derricks are used, and 6 quarrymen and 6 stonecutters are employed. J. P. Allen of Rocklin, manager.

Fletcher's, L., Quarry—It is a small quarry on Granite Street in Rocklin, and worked intermittently. Nine men are employed when the quarry is operated. L. Fletcher of Rocklin, owner.

Griffiith's Quarry and Polishing Works—See our XIIth Report, p. 385. They are ½ mile E of Penryn. Idle. D. Griffith, of Penryn, manager.

Grimes' Quarry—It is a small quarry, 2 miles E of Lincoln. Four men are employed, getting out curbing. Amos Grimes of Lincoln, owner.

Hoyt's Quarry—It is in the eastern part of Rocklin, in SE ¼ Sec. 29, T. 11 N., R. 7 E., at 265′ elevation. Four men are employed, getting out curbing. Howard Hoyt of Rocklin, owner.

Hytimen & Wickman's Quarry—It is ¾ of a mile S of Rocklin, on leased land, in the NE ¼ Sec. 29, T. 11 N., R. 7 E. The open cut is 100′x150′ and 60′ deep; one steam-power and two horse-power derricks are used. Four men are employed, getting out curbing. Hytimen & Wickman, of Rocklin, Managers.

I X L (Jeter) Quarry—It is 2 miles E of Lincoln, at about 170′ elevation. The open cut is about 40′x100′ and 40′ deep. Two horse-power derricks are used. The stone is used for cemetery and building purposes. There are 4 quarrymen and 8 stonecutters at work. T. H. Jeter of Lincoln, owner.

Jacobson's Quarry—It is a small quarry in Rocklin, 25′x50′ and 30′ deep. One derrick is used, and 5 men are employed. — Jacobson of Rocklin, manager.

Jeter Quarry—See I X L Quarry.

Johnson's, M., Quarry—It is a small quarry at Rocklin, in the SE ¼ Sec. 19, T. 11 N., R. 7 E. One horse-power derrick is used, and 4 men are employed getting out curbing.

Kent Quarry—See our XIIth Report, p. 385. It is at Rocklin, and practically abandoned.

Loomis Quarry—It is ½ mile S of Loomis, at 385′ elevation. The open cut is 60′x150′ and 65′ deep. Two steam-power and two horse-power derricks are used. Five men are employed. M. J. Haley of Loomis, owner.

Mantyla's Quarry—It is at Rocklin, near the center of Sec. 19, T. 11 N., R. 7 E. The open cut is about 100′x200′ and 40′ deep. Two steam-power derricks are used. It is worked intermittently, and 5 quarrymen and 5 stonecutters are employed when running. John Mantyla, of Rocklin manager.

McDonald's Quarry—It is a small quarry, 2½ miles SE of Lincoln. Four quarrymen and 2 stonecutters are employed. C. J. McDonald of Lincoln, owner.

Quinn's Quarry—See our XIIth Report, p. 385. It is at Rocklin. The open quarry is 125′ and 75′ deep. Two steam power derricks are used. Three quarrymen, 3 stonecutters, and 2 laborers are employed. Mrs. Mary Quinn, of Rocklin, owner; Quinn Bros., of Rocklin, managers.

Roberts & Fippins' Quarry and Stone Works—The works are at Penryn and the quarry is 1 mile SE of it. Gray

granitic rock is quarried from a large outcrop, and the workings do not extend below the general surface. It is darker than the Rocklin granite, and shows a marked contrast between polished and rough surface. The work consists of a 14 H. P. engine and boiler, a double lathe for turning columns, urns, vases, etc., and machinery for polishing both flat and curved surfaces, mouldings, etc. Three quarrymen, 3 stonecutters, and 3 millmen are employed. D. A. Roberts and A. B. Fippins of Penryn, owner.

Rocklin Granite Co.'s Quarry—See our XIIth Report, p. 386. It is at Rocklin, on leased land, in the SW ¼ Sec. 20, T. 11 N., R. 7 E. The quarry is 150'x250' and about 100' deep. The equipment consists of five steam-power derricks, each of which is capable of hoisting blocks weighing 25 tons each, one traveling crane for handling stone in the sheds, one McDonald stone-cutting machine, one 40 H. P. engine and boiler. The "Krox blast" is used in the quarry. Ten quarrymen, 16 stonecutters, and five laborers are employed. E. M. Hall, Jr., of Oakland, secretary; J. L. Delano, of Rockland, president and manager.

SAN BERNARDINO COUNTY

Sherer Quarries—They are two miles S of Oro Grande, at the side of the Southern California R. R. John Sherer of Victor, owner.

SAN DIEGO COUNTY

Waterman Quarry—It is at Fosters, the present northern terminus of the Cuyamaca and Eastern R. R. It was opened in 1894 for the purpose of quarrying massive blocks of stone for the jetty near Point Loma, at the entrance to San Diego harbor. The contract having been completed, the quarry is now idle and machinery removed. W. S. Waterman of San Diego, owner.

SAN LOUIS OBISPO COUNTY

Lee's Quarry—It is 4 miles NW from San Louis Obispo, at about 425' elevation. The rock is a hard, light gray porphyry, in which the feldspar is partially decomposed. The trimmings for the court-house at San Louis Obispo are said to have been taken from this quarry, and considerable rock from it has been used for railway culverts, bridges, etc. The rock is broken by joint planes, which makes it more or less difficult to get good dimension stone. It is worked by an open cut, 25'x75' and 25' deep. Idle. Chas. Lee of San Louis Obispo, owner.

Morro Rock Quarry—It is near the base of Morro Rock, a conical shaped peak at the entrance of Morro Bay, and is about 600' altitude. The rock is a hard, light gray porphyry in which the feldspar is slightly decomposed. It breaks regularly, and good dimension stone may be easily obtained. It is quarried by contract, and loaded from the quarry on barges by a steam-power derrick. The principal part of the rock quarried is used in constructing a breakwater at Port Harford, and a limited quantity for buildings. The quarry is on a Government reservation.

SHASTA COUNTY

Masterton Bros.' Quarry—It is on Brandy Creek, 1½ miles S of Stella. The granite is coarse-grained, dark, and similar to the Lincoln granite, in Placer County. Only bowlders are worked into curbing and coping, the quality being hardly fine enough for monumental work. Pieces 2"x10"x10' are produced. Four men are at work, 2 quarrymen and 2 stonecutters. Masterton Bros. of Redding, owners.

TRINITY COUNTY

Rush Creek Quarry—See our XIIth Report, p. 387. This is situated on Rush Creek, 6 miles E of Waverville, and contains 40 acres. At present only bowlders are worked. The granite is fine-grained, free from iron, and not very hard. Seven stonecutters are employed. Materton Bros. of Red Bluff, Tehama County, owners.

TULARE COUNTY

Griffith & Owens' Quarry—See our XIIth Report, p 387. It is 3½ miles E of Exeter, on the S. P. R. R. and on the eastern base of Rocky Hill. Practically idle. Griffith & Owens of Exeter, owners.

To be continued.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

Damages for Non-Performance of Building Contract.—In an action for services for construction of a building, the owner, after testifying that he had to complete it himself, and that it took up his time so that he could not attend to his regular business as a merchant, was asked what time he had lost and its value. The court held that the measure of damages in that regard was the value of the time spent as superintendent, and not the value of the time lost to the other business.

Crawford v. Harris, Sup. Ct. Cal., 45 Pacific Rep. 819.

Fences.—An injunction will not lie to restrain an adjoining owner from maintaining a fence 11 feet high on the divison line, which shuts off the circulation of air from other buildings, thus rendering it damp and unhealthy.

Peck v. Roe, Sup. Ct. Mich., 67 N. W. Rep. 1080.

Married Woman's Property in Kentucky.—Under the laws of Kentucky regarding mechanic's liens, a married woman cannot be charged for labor performed, or material furnished in the erection or improvement of buildings on her separate property, without a written contract, even though she acquiesced in the erection of the building, and gave directions about its construction.

Webster v. Tattershall, Ct. App. Ky., 36 Southwestern Rep. 1126.

Effect of Assignment of Contractor's Claim.—Claims against the owner of a building, says the Supreme Court of Indian, for work done or materials furnished in connection with same may be assigned, but they carry no lien unless a lien has been first perfected by the mechanic or material man in whose favor the right to the lien primarily exists.

Jenckes v. Jenckes, 44 Northeastern Reporter, 632.

When Mortgage is Superior to Mechanic's Claim of Lien.—The lien of a mortgage given by the purchaser of real estate to the seller at the time of the conveyance of the legal title is superior to the lien of a material man who furnished material for the construction of a building on such land, the buildings having been commenced before the conveyance of the title; the purchaser having no authority or permission to enter upon or take possession of the premises, for any purpose, before the legal title was transferred.

No. Valley Lumber Co. v. Keid, Ct. App. Kas., 45 Pacific Rep. 722.

BOOKS AND PERIODICALS.

Rule and regulations of the CENTRAL AMERICAN EXHIBITION decreed by the National Legislative Assembly of the Repvblic of Guatemala.

At a time when our merchants are endeavoring to extend their trade with South America it may be well to call their attention to this exhibition which will be inagurated on the fifteenth of March, 1897 and close on the fifteenth of the following July.

This exhibition will be held in the Capitol of the Republi of Guatemala, covering an area of twelve city blocks and 8082 square yards.

The branches admitted to the exhibition will be classed in groups in the following order:

First—Science and literature; 2d Education and instruction. 3rd Fine arts. 4th Machinery and building. 5th Agriculture, horticulture, Arboriculture and cultivations of a special nature. 6th Fauna and Flora. 7th Decorative art. 8th Various industries. 9th Transporation. 10th Transportation. 11th Mining 12th Immigration.

Article 5. The groups into which these branches are divided will be subdivided into classes in conformity with the annexed list.

Article 6. Articles which are offensive to public morals, or deleterious to the general health, will not be admitted to the Exhibition.

Proceedings of the Sixth Annual Convention of the ASSOCIATION OF RAILWAY SUPERINTENDENTS of Bridges and Buildings, held in Chicago, Illinois, October 20, 21 and 22, 1896.

This report contains a list of the members present at roll call as well as to the road they are with and also a list of the application for membership.

The description of this body of railway superintendents, are fully reported and cannot fail to be of interest to those interested in the construction and safe maintenance of bridges and road ways.

A number of drawings of station houses are given and if we may be allowed the remark, they have more the resemblance of the engineers drawing than the work of an architect, doubtless however they answer the purpose for which they were intended.

Annual Report of the Board of Regents of the SMITHSONIAN INSTITUTION, showing the operations, expenditures and condition of the institution to July 1894. Washington Government printing office, 1896.

This valuable document is one that would be missed not only by the scientific world but by the people in general, on account of the large amount of information of value in relation to our every day life. Photography, electricity, agriculture and astronomy are all included among the various researches that are here published. The latest discoveries up to date are here recorded and suggestions of what may be expected in the near future open a wide field of thought.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street.

Seth Babson, Pres. W. P. Moore, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Theo. A. Eisen, Pres. Arthur B. Benton, Vice-Pres.
William C. Aiken, Sec't. August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

Jos. C. Hornblower, Pres. Jas. G. Hill, Vice-Pres.
E. W. Dunn, Jr., Sec. W. J. Marsh, Treas.

Association of Architects of Arizona, meetings held at Phoenix, Arizona.

D. W. Millard, Pres. T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

E. J. Molera, Pres. W. F. C. Hasson, Vice-Pres.
Otto Von Geldern, Sec. Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

Oscar Lewis, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. M. V. Brady, Sec.

THE EXPOSITION OF 1898.

The Exposition site in the northern suburbs of Omaha embraces ample area, is most accessible, and in every way adapted for the purpose. The board of managers passed a resolution providing for the following nine buildings, which will constitute the nucleus around which the smaller buildings will be assembled:

Building No. 1—Agriculture, Horticulture and Forestry; No. 2—Mines and Mining; No. 3—Manufacturers and Liberal Arts; No. 4—Fine Arts; No. 5—Electricity and Machinery; No. 6—Auditorium; No. 7—The Nebraska Building; No. 8—Grand Army of the Republic Building; No. 9—The Silver Palace.

In the discussion regarding these buildings the idea was advanced that the auditorium building should be made a model of the world-famed tabernacle in Salt Lake City, a building renowned as having the most perfect acoustic properties of any auditorium in the world. The material to be used in the construction of the buildings has not been decided upon by the exposition authorities, but it is more than likely that the temporary buildings will be built in the same way as the World's Fair Buildings, of staff, a form of stucco. The plan of the exposition authorities, however, contemplates one or more permanent buildings. It is desired to have four of the buildings built in a permanent and substantial manner, if the arrangements for so doing can be made, but it is certain that some of the buildings will be of a permanent character. The government building will probably be one of these, the purpose of the exposition promoters being to purchase this building after the exposition is over. It is also the purpose to have the auditorium constructed of permanent material.

Application for space at the exposition continue to pour into the department of exhibits and a very flattering showing has been made in a number of different lines. The list of applicants for space is already large and growing daily; manager E. E. Bruce of the department of exhibits announces special prizes, consisting of six gold trophies, six silver cups and six gold medals, to the competitors in each of the following classes: For the best display of an irrigating system in operation; for the best electric light service in display; for the best display illustrating the process of the manufacture of beet root sugar; for the best display of manufacturing plant in operation; as well as two more lots of similar prizes for other high class exhibits to be designated hereafter.

The Exposition will open June first and close November 1, 1898.

FORESTERS' HALL AT PALO ALTO.

Cuthbertson & Williamsons, Architects.

BUSINESS MOSAICS.

The J. L. Mott Iron Works is represented on this coast by Mr. M. S. James, who can be found at room 27, Flood Building. Parties are especially invited to call at their show room and examine the various sanitary appliances as applied to housekeeping. The Hinged Drain Board as shown on the kitchen sink is one among other improvements that demand attention.

Balg—Why do you call your horse She? Burl—Because she makes a rider haggard.

W. W. Montague & Co.—Nowdays when the effect of your rooms is so much improved by a handsome mantel with all the fire place trimmings in keeping, it is well to know where you can depend upon finding the best of every thing in this line of goods. Every article furnished by the above named firm can be depended upon as being what it is represented to be.

You can hardly fail to find what you want in the housekeeping line, either for hotel or private house in the way of heating and ventilation or complete kitchen outfits. Branch stores at Los Angeles and San Jose.

Clark—Why are you going to move, did the owner raise the rent? Schemer—The owner had to, we couldn't.

Joseph Budde, 575 Mission street has so long supplied sanitary appliances in the plumbing line to San Francisco, that it is hardly worth while to call attention to his show room in Mission street but if you will look upon page vii of this journal you will find his advertisement and may be reminded of what you want in his line.

Teacher (serverely)—Tommy Smith, come here. Why haven't you learned your geography lesson? Tommy—'Cause the papers say there's going to be a change in the map of Europe.—*Tit-Bits.*

Dixon Graphite Paint is an article without a rival for the tin or shingle roofs. Architects at the east would laugh if you wished to paint your roof with any thing else. If you want your roof preserved for fifteen years try it.

Virgil says of some of his people: "They can because they think they can." But in the sardine business people can because they have to can.—*Somerville Journal.*

J. W. Burtchaell manufacturer of electric and gas fixtures art glass work, gold, silver, copper, brass and nickel plating, 11 Trinity street, between Bush and Sutter above Montgomery.

The young man who is anxious to lay the world at the feet of the girl he adors, three months after he marries her isn't willing even to lay the carpet.—*Yonkers Statesman.*

J. Leonard contractor for concrete and artificial stone, Spreckels Building, Market street. See advertisement on page xiv of this journal.

Store Propriator—So you want a job as floor walker, do you? Hane you any recommendations? "No, but I'm an experienced hand, Sir. I'm the father of nine children."—*Tit-Bits.*

Samuel Kellett manufacturer of plaster decorations, plastering repaired and whitened, 28 Ellis street, San Francisco and 375 Twelfth street, Oakland.

Owen—What's in a name, anyhow? Dunne—Not much in yours, old man. Owen—What do you mean? Dunne—Why, everything you've got is in your wife's name, isn't it?—*Tit-Bits.*

The Pancoast Ventilator manufactuaed by N. & G. Taylor Co., Philadelphia, Pa., is guaranteed to exhaust more cubic feet of air per minute than any other storm-proof ventilator made. This ventilator is made of black sheet iron and then galvanized. See their advertisement upon page ii.

Mr. Hart (to his wife, teasingly)—Making angel food, my dear? His Wife—No darling. You know if I did there wouldn't be anybody but me to eat it.—*Times.*

As a protection against accidents the Model Window Hinge cannot be too highly recommended, as it affords a safe and easy mode of washing windows without the danger of going outside the house this. If hinge is brought to the notice of the good housekeeper it cannot fail to come into general use.

The office of the company known as "The Model Window Hinge Co." is on 7th floor of the Mills Building, room 5, where the operation as applied to the window can be seen. Do not fail to call if you do not want you neck broken by falling from a window without the model hinge.

CITY BUILDING NEWS.

Alvarado near Douglass. Cottage; owner, Jacob Heyman; days' work; cost $2500.

Alvarado near Douglass. Cottage; owner, John Lynch; cost $1500.

Beal near Bryant. Excavations, brick and cement work; owners, Hobbs, Wall & Co.; architect, T. J. Welsh; contractor, J. F. Riley; signed, Feb. 26; filed, Feb. 27; cost $3000.

Belvedere near Waller. To build; owner, Mrs. M. J. Goodwin; contractor, D. Einstein; signed, Feb. 23; filed, Feb. 24; cost $4050.

Beulth and Schrader. To build; owner, Mrs. Emma J. Purnell; architect, Edgar A. Mathews; contractors, Caldwell & Nickerson; signed, March 3; filed, March 8; cost $1686.

Buena Vista Ave. near Waller. To build; owners, William H. Dick and Mary A. Dick; architect, R. H. White; contractor, White Bros.; signed, March 4; filed, March 5; cost $3800.

California Ave. and Powell Ave. Additions; owner not given; contractor, W. C. Hamerton; cost $1200.

Croke near Mission. Cottage; owner, Louis Metter; cost $1000.

Douglass near Alvarado. To build; owner, John Lander; cost $1500.

El Dorado and Rhode Island. Brick work for garbage crematory; owner, Sanitary Reduction Work; architect, Chas. Thackery; contractors, O. E. Emdy & Son; signed, Feb. 17; filed, March 3; cost $39,680. Roofing work, etc.; contractors, Conlin & Roberts; cost $2010. Carpenter work; contractors, Mascone & Rose; cost $2852. Iron work, etc.; contractors, Josh Hendy Machine Works; cost $19,50.0.

Fell near Laguna. Alterations and additions; owner, J. Silverstein; contractors, Carmichael & Grant; signed, Feb. 8; filed, Feb. 15; cost $2200.

Fell near Buchanan. Alterations and additions; owner, Martha A. Morrison; architect, F. B. Wendt; contractor, Chas. E. Miller; signed, Feb. 22; cost $3570.

Fulton near Lyon. Two-story frame; owner, Mrs. Louise Nieman; architects, Laist & Schwerdt; contractor, Franz & Burmeister; signed, March 4; filed, March 6; cost $3795.

Francis near Mission. Cottage; owner, Frederick Munk; days work; cost $1000.

Geary near Powell. Brick work for five-story brick; owner, A. Aronson; architect, C. H. Weisman; contractor, John F. Riley; signed, Feb. 15; filed, Feb. 24; cost $7500. Carpentery, mill work, etc.; contractor, F. V. Steinman; cost $6500. Sandstone work; contractors, McPhee Co.; cost $3325.

Grant Ave. and Sutter. Alterations and additions; owner, Mrs. Alice P. Sullivan; architect, Edward R. Swain; contractor, Mahoney Bros.; signed, Feb. 11; filed, Feb. 18; cost $10,175.

Grant Ave. and Sutter. Plumbing, gas fitting, etc.; owner, Mrs. Alice P. Sullivan; architect, Edward R. Swain; contractors, Allen & Looney; signed, Feb. 11; filed, Feb. 18; cost $1975.

Green near Scott. To build; owners, Otto C. Gross and H. M. Gross; architect, E. W. Hyde; signed, Feb. 24; filed, Feb. 25; cost $4500.

Green near Montgomery Ave. To build; owner, Mrs. J. Strauss; architect, M. J. Lyon; contractor, R. Fahy; signed, March 8; filed, March 12; cost $3045.

Green near Webster. Alterations and additions; owner, H. W. Luckey; contractor, A. Petry; signed, March 15; filed, March 15; cost $1600.

Greenwich and Jones. To build except plumbing; owner, Julius Riemer; architect, W. H. Armitage; contractor, L. M. Weisman; signed, March 9; filed, March 10; cost $3440.

Grove near Steiner. To build; owner, J. J. Crone; cost $5000.

Gough near Fulton. To build; owners, Giesen Bros.; contractor, G. T. Knopf; cost $3000.

Jackson and Octavia. Excavations, brick and granite work for two-story; owner Mrs. Isaac Hecht; architect, J. E. Krafft; contractors, Miller & Beck; signed, Feb. 11; filed, Feb. 11; cost $4950. Carpenter work, etc.; contractor, C. Chisholm; cost $16,400. Plumbing; S. Ickelheimer & Bro.; cost $2185. Painting, etc.; contractor, J. St. Denis; cost $1090.

Kentucky near 18th. Two-story frame; owner, James McHugh; contractor, R. O. Davis; signed, March 12; filed, March 15; cost $1250.

Lotta near Parnassus Ave. Cottage; owner, Ida H. Lutgen; contractor, W. W. Redmall; signed, Feb. 11; filed, Feb. 13; cost $2350.

Mission near 23d. Alterations and additions; owner, Chas. F. Guinlan and minor heirs; architect, B. J. Clinch; contractors, E. J. Thayer & J. H. Hughes; signed, Feb. 10; filed, 16; cost $1700.

Manchester near Stoneman. Additions; owner, Aug. Voss; contractor, H. Behrens; cost $800.

Montgomery junction of Bay. Frame building for manufactury; owner, Staffer Chemical Co.; day's work; cost $8000.

Nebraska and Cortland Ave. Cottage; owner, Henri Pottet; architect, E Depierre; contractor, R. Trost; signed, March 5; filed, March 6; cost $1474.

Ninth Ave. near "I" street. Cottage; owner, John F. Ritter; architect, Aug. Nordin; contractor, G. W. Hansbrough; signed, Feb. 24; filed, Feb. 26; cost $1500.

Ninteenth and Howard. To build; owner, O. Falch; architects, Martens & Coffey; contractor, C. Schutt; signed, Feb. 26; filed, Feb. 27; cost $3350. Plumbing, etc.; contractor, G. S. Sweeney; cost $1099. Painting; contractor, F. S. Schaefer; cost $570.

O'Farrell near Powell. Alterations and additions; owner, Thos. J. Regan; architect, T. J. Welsh; contractor, James E. Mooney; signed, Feb. 24; filed, Feb. 25; cost $4800.

O'Farrell near Powell. Excavation, etc.; owner, Thos. J. Regan; architect, T. J Welsh; contractor, Thos. J. Mooney; signed, Feb. 24; filed, Feb. 25; cost $2000.

Park Alley near Clay. To build; owner, D. T. and Anna Herzog; contractor, John Byron; signed, March 8; filed, March 12; cost $1275.

Post Office Building at Ferry Depot. Elevator; owner, Board of Harbor Commission; contractors, Cahill & Hall; cost $750.

Polk near Pine. Alterations and additions; owner, Julius Duetch; architect Wm. H. Wharff; builder, Geo. Trozler; days work; cost $900.

Pt. Lobos Ave. and 25th. To build; owner, W. A. Lowler; contractor, Louis Cereghino; signed, Feb. 19; filed, Feb. 26; cost $1800.

Pierce near Filbert. To build; owner, James Owens; architect, J. V. Campbell; contractor, Daniel Powers; signed, March 2; filed, March 3; cost $1800.

Sacramento near Davis. Brick and terra cotta work for two-story brick; owner, Estate of J. G. Fair; architect, Ed Owens; contractors, Miller & Beck; signed, Feb. 24; filed, March 1; cost about $10,000.

Sansome and Hallock. Elevators; owner, Jacob Stern; architects, Pissis & Moore; contractor, W. L. Holman; signed, Feb. 10; filed, Feb. 17; cost $3768.

Sansome and Hallect. Painting brick building; owner, Jacob Stern; architect Pissis & Moore; contractor, M. J. Donovan; signed, March 9; filed, March 12; cost $1500.

San Jose Ave. near 29th. To build; owner, J. Bluxome; contractor, John B. Glunz; signed, Feb. 25; filed, Feb. 25; cost $2352.

Stockton and Market. One-story brick; owner, O. D. Baldwin; day's work; cost $5000.

Shrader near Waller. To build; owner, J. K. Fraser; architect, W. Koenig; contractor, J. W. Coburn; signed, March 2; filed, March 2; cost $4290.

Surry near Diamond. Cottage; owner, F. C. Sowler; cost $1000.

Tenth Ave. near Clement. To build; owner, Charles F. Muller; architect, Wm. H. Armitage; contractor, Harry Wharton; signed, March 9; filed, March 15; cost $2400.

Twenty-second and Chattanooga. Cottage; owner, J. H. Van Glahn; contractor, G. M. Salsburg; signed, Feb. 26; filed, March 1; cost $1260.

Twenty-second and Chattanooga. Cottage; owner, J. H. Van Glahn; contractor, G. M. Salsbury; signed, Feb. 26; filed, March 2; cost $1290.

Twenty-third near Douglass. Cottage; owner, John Oswald; cost $1600.

Taylor near Clay. Three-story frame; owner, John Dunn; architects, McDougall Bros.; contractor, John H. McKay; signed, Feb. 15; filed, Feb. 16; cost $8727.

Van Ness Ave. and Elm Ave. Alterations; owner, I. Lowenberg; architects, Salfield & Kohlberg; contractor, John Furness; signed, March 8; filed, March 9; cost $1186.

Waller near Webster. Cottage; owner, Catherine Wren; contractor, Frank Gallagher; signed, Feb. 15; filed, Feb. 19; cost $1570.

Waller near Masonic Ave. Two-story frame; owner, Minnie Wheeler; contractor, T. T. Pottinger; signed, March 4; filed, March 5; cost $4200.

Waller near Masonic Ave. To build; owner, C. R. Wilson; contractor, A. W Jones; signed, March 6; filed, March 6; cost $5450.

Waverly Place near Sacramento. Excavations, etc., for two-story brick; owner Paul Fleury; architects, Pissis & Moore; contractor, M. V. Brady; signed Feb. 26; filed, Feb. 26; cost $1480.

Waverly Place near Sacramento. Carpenter work, etc.; owner, Paul Fleury, architects, Pissis & Moore; contractor, F. W. Kern; signed, Feb. 23; filed, Feb. 25; cost $1030.

Willard near Adeline. Frame building; owner, R. A. Vance; days' work owner, R. A. Vance; days' work; cost $6000.

The California Architect and Building News.

OFFICE, 408 CALIFORNIA STREET, SAN FRANCISCO, CAL., U. S. A.

VOLUME XVIII. APRIL 20th, 1897. NUMBER 4

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

Published on or about the 20th of each month by The California Architectural Publishing Company. The Stockholders being Architects and others interested in the profession.

SUBSCRIPTION TO THE JOURNAL, - $3.00 PER YEAR IN ADVANCE.

ESTABLISHED 1879. INCORPORATED 1889
NOW IN THE EIGHTEENTH YEAR.

OLIVER EVERETT Secretary.

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

WHILE the late Legislature of California is open to criticism for sins of omission as well as sins of commission, it passed one bill that is a meritorious one, and will tend to simplify materially the transferring of land and thus facilitate its purchase and sale. The bill is the one popularly known as the Torrens' bill, which we have frequently commented upon in these pages. In another column we give the more important sections of this bill in full, and a resume of all its provisions, believing the importance of the measure to all real estate holders justifies the amount of space occupied.

THE PUBLIC has been at last aroused as to the want of a new United States Government Building in San Francisco—the persistent efforts of the CALIFORNIA ARCHITECT AND BUILDING NEWS we hope have tended to this result.

Representatives of all the leading business interests in the city met at the Chamber of Commerce and adopted a memorial to Congress, urging that the work be begun immediately. The Trades Unions are also one with this.

The *Examiner* has the following to say on the subject:—"Once more information that work is about to begin on the San Francisco Post-Office comes from Washington to comfort and to cheer. However, as the years fleet by it is losing a measure of its power in this direction."

E SEE by late exchanges the war ship Oregon has gone upon the rocks at the entrance of the Dry Dock—the extent of damage as yet unknown but evidently of a serious nature.

Is it not about time to call a halt upon building these immense unmanageable monsters, that appear to be more dangerous to those that navigate them than to the enemy they are supposed to attack.

A Government that appears to be too poor to construct a post-office building for San Francisco, after ten years trial, should not waste millions upon millions to produce more war ships that they can not navigate from one port to another without wrecking.

E ARE glad to see that Mayor Phelan is attempting to prevent the taking up of the sidewalks by the show windows of shop-keepers by vetoing permission to grant the same.

We cannot do better than to give the reasons for refusing such permission in his own words:

"The evil has grown by reason of the fact that one property owner extends his show window over the sidewalk, thus compelling his neighbor to do the same, and so on progressively until all the show windows are projected. If the privilege was not granted in the first instance, every property-owner would be compelled to occupy his own land. He could produce the same effect on his own line by making embrasures instead of projections, and the public would not be the sufferers. As it is now one foot is taken off the sidewalk and given to the property-owner, thus narrowing the channel over which people are compelled to pass, inconveniencing and crowding them into the roadway. Such an absorption of the sidewalk is certainly in derogation of the rights of the citizen to its free and full use."

BILLS OF QUANTITIES AND THEIR RELATION TO BUILDING CONTRACTS.

PAPER READ BY G. ALEXANDER WRIGHT BEFORE THE SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS, FEBRUARY 12, 1897.

[CONTINUED FROM LAST ISSUE]

WE WILL now dwell for a moment upon what is being done in other large communities.

In 1891 I visited Melbourne, Australia, the most American city probably in the world, outside the United States—and there the quantity system had been in operation for twelve years or more. In Sydney, N. S. W., it was my privilege to exchange views very fully upon this subject with the president of the Institute of Architects (Mr. Horbury Hunt) and who by the way is an American—who informed me that the architects and builders of the city had just joined hands in the adoption of the quantity surveyor. In Scotland, quantities are used—the same system prevails in England and Ireland—and in Continental Europe a somewhat similar system of measure and value is found in various forms, and although not exclusively the case, the principle, of *so much work* (by measurement) for *so much money*, appears to find favor.

I know of no community where that principle, having once been adopted has been abandoned for the system such as we use here in San Francisco to-day. Nevertheless, we need not copy the system of *any* particulaa place. We can, if necessary, frame a system of our own—and adapted to the local needs of all parties concerned—and who can tell that such a system may not form the basis of one uniform national system for the entire union? I have reason to think that the necessity for some thing of this kind is being felt.

I have had some correspondence recently with Prof. Ware the editor of the *American Architect*, and that gentlemen writes me that he has long been hoping to see some modification of the quantity system universally adopted in this country, and he is not alone in this opinion, and I believe it would be a distinct step in advance if San Francisco could be the first city to take up this question in an organized way and to examiner it.

But I want to speak to you, upon the *advantages* of the quantity system as "briefly" as I know how. In the first place it will save at least one-half of the contractor's time and labor, and which is entirely unproductive *now*. Time we are told is money—and without question, unproductive labor is "waste"—and I believe it is beginning to be recognized. One frequently hears builders and material men say "I am about *tired* of figuring, there is nothing in it, etc.," but it is not to be *wondered* at. I noticed in one of the building papers the other day, a strong protest from a San Francisco contractor against the present unsatisfactory method of estimating and it is not so very long ago that a Boston architect (Mr. Rodman of Boston I think it was) had something to say in one of the professional journals on the subject. He denounced the present system of estimating as reckless, unscientific, and unpractical and I can but endorse his views.

Take the mill work of any large job for example—may be there are half a dozen millmen—all going over exactly the same ground, doing precisely the same thing either at the arohitect's office or elsewhere. A number of brickmen are doing the same in their department—then the concrete men come, and the masons, and the iron men, (but I needn't go through the list we are all familiar with them) twenty, thirty or even forty men or more, figuring in different departments for one job—and this goes on year in and year out—at least ninety per cent of these workers throwing away time and brains. Would they not be more profitably employed in supervising, more closely, what work they already have? and *yet*, the bulk of the work done by these thirty or forty men, could be done by *one* man. As *well*, you say? Why certainly, gentlemen, and I think with advantage to many a builders banking, account.

It has been said that it is better to have the contractor make out his own quantities as well as make up the money estimate. But *does* he (*as a general rule*) do *either* of these things—*now*, I know *some* who *may* do so; but *is* it not a *fact* that the tendency is largely to collect together all the cheapest bids that can be got fram material men and mechanics. The result added to the rough lumber bill perhaps, with something for labor and profit often times forms the "figure." I do not say this is not perfectly legitimate, under the present method, but the ease with which these sub bids are obtained indicates that it is frequently the *sub* bidders who do the bulk of the estimating, of course as I say, with certain exceptions. I remember an interesting point as showing the extent to this practice. There was a case before the courts some three years ago in which I was called as a wit — The issue was a *simple* one, viz: the actual value of a large building standing not far from us now. Several contractors were called as "experts" on both sides, some of these testified as to the value of the building, but under cross examination it transpired that their valuations were made up largely from figures or bids furnished to them for this particular purpose, and so they were testifying upon the strength of somebody else's opinion, and which as the Judge said, was not *evidence*, nor, was it estimating in the proper sense.

Another advantage of the quantity system is that it tells a bidder exactly in black and white, what he is to figure upon, there can be no mistaking what is meant, and we should hear less about omitting to figure items that ought to be figured. A bill of quantities is valuable and indisputable evidence upon all sueh points. Many a bidder can probably recall instances where he lost money upon a contract, though omitting something and which never *could* have occured if he had been bidding under the quantity system.

Another point for your consideration, would the quantity *system* place the incompetent man upon a level with the competent one? in other words, would the incompetent gain any advantage? I say *no*, it would be more likely to be the other way round, and my reason is this. An incompetent estimator is far more likely to forget something thah he is to include too much, this is an established fact, and competitors who *do* get in all their items are handicapped from the start by men who do not. They never know what kind of a break the other fellow will make. I have in the past been there myself and speak from experience. With quantities all are bound to *start* level as regards "quantity" and nine times out of ten this is an advantage to the best men, individual skill and judgment in *pricing*, will tell just as much as *with* quantities as *without* them, and the incompetent, will have a bigger fight on their hands than with the present method. The trouble unfortunately, does not end here. The best estimators have to protect themselves against the omissions of the incompetent. They do so by cutting their itemized prices down to cost, or nearly so, and to-day the keen competition job, is scarcely worth having as far as "profit" is concerned. Dull times are not wholly to blame for low prices, incompetent estimators have something to do with it.

Again, take changes on contracts and this is where that schedule, we filed away in the architects safe is *useful*.

Upon a change being contemplated or executed, it is an easy matter to get at the quantity of material added and omitted, figure it out at the *competitive*, prices given in the schedule and the whole thing is settled, without the chance of a dispute about the payment for the changes. It is all very well to say, disputes don't often occur but when they *do* occur, it is well for both contractor and architect to have something at hand, that will settle them at once, and with absolute fairness to the owner and contractor, quantities will *prevent* disputes usually, which is still better. In a recent case, which came into my hands as an arbitrator a bill of quantities would have been of great value in determining the liabilities and rights of the parties to the arbitration—indeed it is possible that an arbitration would never have been necessary at all.

But I need not occupy your time with further illustrations beyond saying perhaps that the specifications can be made much shorter than is usually done, for the quantities would contain all necessary detailed descriptions.

In concluding this section of my paper, I may remind you that neither the architect nor the contractor are put to the slightest expense for quantities, and I do not suppose that any class of mechanics or builders will seriously object to a document, which is the best of all guarantees in black and white, that they will not be called upon to do a dollar's worth more work than is *stated* (in detail) and is called for by the "quantities."

It might be well to see you a moment how the quantity system would affect the owner.

Before any such system can be adopted, a proper understanding between architects and contractors, is essential. All the available information, and data, on the subject should be obtained. Let the system be thoroughly investigated. If it is then desirable, a uniform standard of measurement for everything in a building—agreeable to all parties, should be established so that the technical terms, descriptions, order and method adopted in *all* quantities (by whomsoever prepared) should be uniform throughout, so that they may be readily understood by all bidders methodical course is essential, so that after pricing one or two sets of quantities, contractors will know exactly where to find any particular item.

To meet any doubt as to the possibility of one contractor set of quantitses being more advantageous than anothers it would be an easy matter to have, open for free inspection one spare copy of the quantities on file at the architect's office, and another, say in the directors room of the Builders' Exchange. This opportunity for verification by any bidder would prevent improper practices, but such details as these might be easily arranged. We will assume now that an owner (whilst very righly trying to obtain a good building at the lowest market price) is willing to pay a fair and legitimate sum for honest and legitimate work. That owners wants an "estimate" or *bid*. Now he does not want it to be any more, than it ought to be, and the contractor does not intend it to be any less. Now it is an impossibility to get an accurate estimate, without accurate quantities, and which are essential to the owner's interest and he must be so informed, and that the expense will be included in the bids.

In view of the work put into modern buildings, compared with that of early days, it is unjust on the part of owners, to expect each contractor to furnish quantities, as well as to calculate cost values, the latter is their legitimate field, but the owner should, through the quantity surveyor say how *much* lumber, *how much* brick work, how many pounds of steel, etc., etc., his agent, the architect has decided to use.

A contractors estimate of the cost of a building, that is the *lowest* estimate is the very thing the owner needs the most, and it is "custom" alone, and a very bad custom at that which has brought about the present one sided condition of things. It matteas not, gentlemen, how long the present method has continued it is wrong in principle, bad in equity, and very largely unproductive in practice to contractors. No body of men are justified in performing unproductive labor, even though custom *has* sanctioned the practice. As I said in the *American Architect* of January 23rd:—

"An owner may decline to build on receiving bids, upon any pretence; he may in his heart never have intended to build at all, unless he saw a chance of getting two dollars of a builder's money for one of his own, and yet he now gets his estimate for *nothing*. This does really seem absurd.

An owner pays (or should pay) his architect for what work he may do, and if the owners be made to see the advantages to themselves of the quutity system, they should be willing to pay for the quantities also. Such a practice, when the justice of it became understood, would not prevent honest owners from building, but it might deter the "grasping" owner (the man who imagines the architect's special duty is to help him to rob the builder); it might deter these men, from defrauding builders out of their time and experience, as is sometimes the case under present conditions."

I remember some months ago, in discussing this "quantity" question I expressed the opinion that if the owner could not be prevailed upon to furnish quantities, he should at least contribute something towards the cost of the estimate, especially where no bid was accepted, and I notice that quite recently the same thing has been suggested in the official journal of the National Association of Builders, published at Boston, still, although this plan may have its advocates, the introduction of some system, of so much work, for *so much money*—is I think, the only true remedy for present evils.

One advantage of quantities to the owner is, that supposing bids exceed the contemplated expenditure, as they have a way of doing sometimes, the cost of the building might easily be cut down, without re-figuring, by striking out of the quantities such items as can be dispensed with, still retaining the balance of the estimate, at legitimate competitive prices, which as I have pointed out, would also apply to any changes, etc.

Again, the less desirable class of contractors or those less skilled in determining money values, will hardly run the risk of figuring on less material than is called for by the quantities, and as they cannot buy any cheaper than the more responsible men the chances will be in favor of the best men being the lowest bidders and this, if not a direct money advontage, will at least favor good work, certainly the more accurate the estimate, the less temptation there is to do anything improper.

I hope no gentlemen will accuse me of professional sacrilege, if I say that from the average owners point of view, the *cost* of a building, is to *him* of almost, or quite, as much consequence, as the *design*—and yet, although he may occupy several months perhaps in making up his mind what he wants, the vitally important question to him, and to the contractor, of what it will cost? has as a general thing to be rushed through almost at lightning speed and as though his very existence depended upon it.

If a building does not go on by reason of the owner deciding not to build, he of course still has to pay for the quantities. They were essential to a proper estimate—which he has received, and can be used, just as soon as he decides to go on. In a general way I think it is an equal and reasonable dividing up of the responsibility, for the owner to furnish the quantities if the contractor furnishes the money estimate. The great progress which is being made in modern building construction, certainly suggests the need of some corresponding improvement in the manner of estimating and taking bids.

In conclusion, gentlemen, I hope I have not detained you too long, beyond the time which should be occupied for a paper of this kind. I much appreciate your kind invitation to be present to-day and I thank you Mr. President and gentlemen for you courteous attention.

AN ACT FOR THE CERTIFICATION OF LAND TITLES AND THE SIMPLIFICATION OF THE TRANSFER OF REAL ESTATE.

Section 1. Recorders and ex officio Recorders in the several counties of this State shall be registrars of titles in their respective counties, and their deputies shall be deputy registrars. All laws relative to recorders and their deputies, including their compensation, clerk hire, and expenses, shall extend to registrars and their deputies, so far as the same may be applicable, except as in this Act otherwise provided. Registrars of titles shall be county officers within the meaning of the laws of this State.

Sec. 2. The official bonds now required by law to be given by Recorders and ex officio Recorders before entering upon the discharge of their duties, shall also apply to and cover the faithful discharge of their duties as registrars, whether such additional condition be specifically provided for in such bonds or not.

Sec. 3. Deputies may perform any and all duties of the registrar, in the name of the registrar, and the acts of such deputies shall be held to be the acts of the registrar.

Sec 4. Registrars and deputy registrars are prohibited from practicing law, or acting as attorneys or counselors at law, or having as a partner a lawyer or any one who acts as such, or from acting as searchers of title under this Act.

BRINGING LAND UNDER THE ACT.

Sec. 5. Land may be brought under the operation of this Act by the filing with the County Clerk of a verified petition to the Superior Court of the county within which such land is situated, by the owner of any estate or interest in such land, whether legal or equitable (other than an undivided share, or an easement). The Clerk shall immediately indorse on such application the exact time of its presentation, and enter the same in a book kept for that purpose and known as the Land Register Docket. Persons who collectively claim to hold the entire legal estate in fee simple may jointly file such petition. A corporation may apply by its authorized agent, an infant by his guardian; any other person under disability by his guardian or trustee. Land constituting a single parcel and lying partly in two or more counties may be included in one application, which may be made in either county in which the land lies, but the certificate issued therefor must be filed with the registrars of all the counties within which such land is situate. Two or more parcels of land may be included in one application if owned by the same person and in the same right.

Sec. 6. The petition shall set forth substantially:

(*a*) The name, occupation, place of residence, and post-office address of the applicant, and if the application is by one acting in behalf of another, the name, place of residence, post-office address, and capacity of the person so acting, and the nature of the disability of the person for whom he is acting.

(*b*) Whether the applicant (except in case of a corporation) is married or not, and, if married, the name and residence of the husband or wife.

(*c*) The description of the land.

(*d*) The applicant's estate or interest in the same, and whether the same is subject to an estate of homestead.

(*e*) Whether the land is occupied or unoccupied, and, if occupied, the name and post-office address of each occupant, and what estate or interest he has or claims in the land.

(*f*) Whether the land is subject to any easement, lien, or incumbrance, and, if any, the name and post-office address [if known] of each holder thereof, and the nature and amount of the same, and, if recorded, the book and page of the record.

(*g*) Whether any other person has any estate or claims any interest in the land, law or in equity, in possession, remainder, reversion, or expectancy, and, if any, the name and post-office address [if known] of ever such person, and the nature of his estate or claim.

(*h*) The names and post-office addresses of all the owners of the adjoining lands, so far as he is able, upon diligent inquiry, to ascertain the same.

(*i*) If the applicant is a male, that he is of the full age of twenty-one years; if a female, that she is of the full age of eighteen years. If the application is made by a corporation, its name, when and where incorporated, its principal place of business, and the names and post-office addresses of its president and secretary. If the application is by a husband or wife, and the property is community property, the petition must so state, and both spouses must join therein. A plat or plan of survey of the land made by the county or a licensed surveyor must accompany the application, and if said land is a part of a city, town or subdivision, the application must refer to the book and page of the records of the county where the map of said city, town, or subdivision is recorded, if at all.

Each application must be accompanied by an abstract of the title, verified by the searcher making the same, as required in proceedings in partition, or, if made by a corporation engaged in the business of making and certifying abstracts of title, then in lieu of the affidavit a certificate by such corporation, under its seal, shall be sufficient. When the title to the land in question has been previously determined by a final decree of a court of competent jurisdiction, such abstracts need not antedate such decree unless required by the court in which such application is filed. No person or corporation shall be authorized to make or furnish such abstracts of title until after entering into an undertaking with two or more sufficient sureties to the people of the State of California in a sum not less tnan [ten] thousand dollars, which may be increased from time to time by order of the court. Such bonds shall be recorded in the record of official bonds in the Recorder's office of the county and then filed in the County Clerk's office. Said bond shall be conditioned to pay all damages and costs which the State may sustain by reason of any error or insufficiency in said abstract. The sureties on such bond shall qualify as provided in section ten hundred and fifty-seven of the Code of Civil Procedure, and the sufficiency of the bond and of the sureties thereon shall be approved by a Judge of the Superior Court of the county where such bond is to be filed. The sureties upon such bond may become severally liable in portions of not less than five hundred dollars each, making in the aggregate at least two sureties for the whole sum. Said bond shall be renewed as often, at least, as once in every period of three years.

Sec. 7. No mortgage, lien, charge, or lesser estate than a fee simple shall be registered unless the fee simple to the same land is first registered.

Sec. 8. It shall not be an objection to bringing land under this Act, that the estate or interest of the applicant is subject to any outstanding lesser estate, mortgage, lien, or charge; but every such lesser estate, mortgage, lien, or charge shall be noted upon the certificate of title and the duplicate thereof, and the title or interest certified shall be subject only to such estates, mortgages, liens, and charges as are so noted, except as herein provided.

Sec. 9. No title derived through sale for any tax or assessment shall be entitled to be first registered, unless it it shall appear to the satisfaction of the court, upon the hearing of the application, that the applicant, or those through whom he claims title, have been in the open, actual, continuous, uninterrupted, undisputed, exclusive, and adverse possession of the land under such title at least five years, and have paid all taxes and assessments legally levied thereon for five successive years.

Sec. 10. The application may be amended only by petition vertified as in the case of the original. Such amendment may be ordered by the court on its own motion, or upon the motion of any person interested in the proceeding.

Sec. 11. The filing of the application in the office of the County Clerk shall be sufficient notice of the same to all subsequent purchasers or incumbrancers without the filing of a *lis pendens* in the office of the Recorder.

Sec. 12. The court shall, in its discretion, examine the abstract itself, or refer the same, as provided in section [eighteen] of this Act. If it shall appear to the court, from an examinotion of the abstract, or from the report of the referee, that the title to the land described in the application is substantially as alleged by the applicant, the application shall be set for hearing, otherwise the court may order the application [dismissed.]

Sec. 13. When the time and place for hearing the application is fixed by the court, notice thereof shall be given to all parties interested, as shown by the petition and the abstract or referee's report, and to the husband or wife of the applicant, if married, and the owners of adjoining lands, in the same manner as the service of a summons in a civil action, [and] [by publication for at least four weeks, in some newspaper of general circulation, to be designated by the court;] *provided*, that no copy of abstract or map need be served with the petition. Any person interested may appear and object to the granting of the application, and if such objection is sustained, the costs of the same shall be paid by the applicant; if not, by the person so objecting. The time for appearance after service shall be the same as in the case of a civil action.

Sec. 14. Upon the day set for the hearing of tne application, or at such time as the same may be continued to, the court shall cause examination to be made into the applicant's title to the land in question, and shall hear testimony as to the allegations of the petition, or of any objections thereto; and if any defects are found in the application, or in the applicant's title to the land, or if any of the allegations of the petition are found to be untrue, or any objections to said petition are sustained, the court may dismiss such application, or may give the applicant such time as the court may deem reasonable, before finally passing upon his application.

Sec. 15. If it shall be made to appear, to the satisfaction of the court, that the notice required by section thirteen has been duly given and served; that the facts stated in the application are true, and that the applicant is the owner of the land, or interested therein, as set forth in the petition, the court shall duly make, give and enter a decree to that effect, which said decree shall contain an accurate description of the property in question, with a diagram thereof, and also shall set forth all liens and incumbrances on said land, with the name of the holder thereof, and the nature, amount, and order of the same, and, if recorded, the book and page of the

record. Any party aggrieved by such decree may appeal therefrom in the manner now or hereafter provided by law for appeals in civil actions.

Sec. 16. A certified copy of such decree shall be filed in the office of the registrar, who shall thereupon issue a certificate of title to the person entitled thereto as shown by said decree, and shall proceed to bring said land under the operation of this Act, as herein provided. Said certificate shall contain the description of the property set forth in the decree, and shall also show the nature, amount and order of the liens thereon.

Sec. 17. The decree of the court ordering registration shall be in the nature of a decree in rem, and shall be final and conclusive as against the rights of every and all persons, known and unknown, to assert any estate, interest, claim, lien, or demand of any nature or kind whatever, against the land so ordered registered, except as provided in this Act.

Sec. 18. Upon the filing of the partition the court may appoint a referee to examine and report upon the abstract accompanying the same. Such referee shall be an attorney in good standing, skilled in the examination of titles, of not less than three years' practice at the bar of the court so appointing him. The compensation of the searcher and of the referee shall be fixed by the court, or agreed upon between themselves and the applicant, and shall be paid by the applicant as a part of the costs of the proceeding.

Sec. 19. Provides that the written opinion of referee is to be filed before decree is made.

Sec. 20. Provides that applicant may withdrow application upon payment of fees at any time prior to issuance of certificate of title.

Sec. 21. Provides that on transfer of interest or death of applicant, proceedings may be continued.

Sec. 22. Provides that Registrar is to keep record of particulars of issuance.

Sec. 23. Provides that certificate of title is to be in duplicate; its contents; original to be retained by registrar.

Sec. 24. Provides form of certificate.

Sec. 25. In all cases where two or more persons are entitled as tenants in common to an estate in registered land, such persons may receive one certificate for the entirety, or each may receive a separate certificate for his undivided share.

Sec. 26. Provides that registered owner may consolidate several or divide up one certificate.

Sec. 27. Provides that certificate may be issued by order of court in lieu of lost duplicate; proceedings therefor.

Sec. 28. If an owner's name or description is incorrectly registered, or becomes changed (*e. g.* by marriage, adoption, divorce, etc.), the court, upon the filing of an application and proof of facts in the manner set forth in section [twenty-seven] of this Act, and the production by the owner of the duplicate certificate, shall order the registrar to issue a new certificate, with such changes as the case may require.

THE REGISTER OF TITLES.

Sec. 29. Provides for original certificate to be entered in register; memorials to be on latest certificate.

Sec. 30. Provides for receipt to be given for duplicate certificate on its issuance.

Sec. 31. In every case of first registration of land or an estate or interest therein, the same shall be deemed to be registered under this Act, when the registrar shall have marked upon the certificate of title, in duplicate, the volume and *folium* of the register in which the original may be found.

Sec. 32. Every transfer or registered land shall be deemed to be registered under this Act. when the new certificate to the transferee shall have been marked, as the case of the first registration; and all other dealings shall be considered as registered when the memorial or notation shall have been entered in the register upon the *folium* constituted by the existing certificate of title of the land. But, for the protection of the transferee or person claiming through any transfer or dealing, the registration shall relate back to the time of filing in the registrar's office the deed, instrument, or notice, pursuant to which the transfer memorial or notation is made.

Sec. 33. Provides that party aggrieved may bring action against registrar and others.

EFFECT OF REGISTRATION.

Sec. 34. The registered owner of any estate or interest in land brought under this Act shall, except in case of fraud to which he is a party, or of the person through whom he claims without valuable consideration paid in good faith, hold the same subject only to such estates, mortgages, liens, charges, and interests as may be noted in the last certificate of title in the registrar's office, and free from all others, except:

1. Any subsisting lease or agreement for a lease for a period not exceeding one year, where there is actual occupation of the land under lease. The term "lease" shall include a verbal letting.

2. All public highways embraced in the description of the lands included in the certificate.

3. Any subsisting right of way or other easement, however created, upon, over, or in respect of the land.

4. Any tax or special assessment for which a sale of the land has not been had at the date of the certificate of title.

5. Such right of action or claim as is allowed by this Act.

6. Liens, claims, or rights arising under the laws of the United States, which the Statutes of California cannot require to appear of record upon the register.

Sec. 35. After land has been registered no title thereto adverse or in derogation to the title of the registered owner shall be acquired by any length of possession.

Sec. 36. Except in case of fraud, and except as herein otherwise provided, no person taking a transfer of registered land, or any estate or interest therein, or of any charge upon the same from the registered owner, shall be held to inquire into the circumstances under which, or the consideration for which, such owner or any previous registered owner was registered, or be affected with notice, actual or constructive, of any unregistered trust, lien, claim, demand, or interest; and the knowledge that any unregistered trust, lien, claim, demand, or interest is in existence shall not of itself be imputed as fraud.

Sec. 37. In case of fraud, any person defrauded shall have all rights and remedies that he would have had if the land were not under the provisions of this Act; *provided*, that nothing contained in this section shall affect the title of a registered owner who has taken bona fide for a valuable consideration, or if any person bona fide claiming through or under him.

Sec. 38. If a deed or other instrument is registered, which is forged, or executed by a person under legal disability, such registration shall be void; *provided*, that the title of a registered owner, who has taken bona fide for a valuable consideration, shall not be affected by reason of his

claiming title through some one, the registration of whose right or interest was void, as provided in this section.

SEC. 39. No unregistered estate, interest, power, right, claim, contract, or trust shall prevail against the title of a registered owner taking bona fide for valuable consideration or any person bona fide claiming through or under him.

SEC. 40. Provides that in absence of fraud, certificate of title is conclusive evidence in suit for specified performance of contract to purchase.

SEC. 41. Provides that in ejectment or partition suits,

Sec. 42. Provides for the register to be received as evidence.

certificate is conclusive evidence.

SEC. 43. Whenever a memorial has been entered, as permitted by this Act, the registrar shall carry the same forward upon all certificates of title until the same is canceled in some manner authorized by this Act.

SEC. 44. All dealings with land or any estate or interest therein, after the same has been brought under this Act, and all liens, incumbrances, and charges upon the same subsequent to the first registration thereof, shall be deemed to be subject to the terms of this Act, and to such amendments and alterations as may hereafter be made. The bringing of land under this Act shall imply an agreement which shall run with the land, that the same shall be subject to the terms and provisions of the Act and of amendments and alterations thereof.

SEC. 45. No person shall commence any action at law or in equity for the recovery of land, or assert any interest, right in, or lien or demand upon the same, or make entry thereon adversely to the title or interest certified in the first certificate bringing the land under the operation of this Act, unless within five years after the first registration. It shall not be an exception to this rule that the person entitled to bring the action or make the entry is an infant, lunatic, or is under any disability, but action may be brought by such person by his next friend or guardian. It shall be the duty of the guardian, if there is any, to bring action in the name of his ward whenever it is necessary to preserve or enforce the wards rights in registered land; *provided, however*, before such action shall proceed, it must be made to appear to the court that the person bring such action, or those under whom he claims, had no actual notice of the proceedings to register such lands in time to appear and file his objections or assert his claim.

SEC. 46. The action provided for in the last preceding section, shall in no way affect or disturb the rights of any person in said land, acquired subsequent to the registration thereof, bona fide and without knowledge, and for a valuable consideration.

SEC. 47. Any person having any interest, right, title, lien, or demand, whether vested, contingent, or inchoate, in, to, or upon registered land, which existed at the time the land was first registered, and upon or for which no cause of action shall have accrued at the date of the registration of the land, may, prior to the expiration of said five years after such registration, file in the registrar's office a notice, under oath, setting forth his interest, right, title, lien, or demand, and how and under whom derived, and the character and nature thereof; and if such claim is so filed, an action may be brought to assert or recover or enforce the same at any time within one year after the right of action shall have accrued thereon, or at any time within the period of five years after said registration, and not afterwards. It shall be the duty of a life tenant or trustee to file such claim on behalf of any remainderman or reversioner, whether the remainder or reversion be at the time vested or contingent, and of a guardian to file such claim on behalf of his ward.

SEC. 48. A registered owner of land desiring to transfer his whole estate or interest therein, or some distinct part or parcel thereof, or some undivided interest therein, or to grant out of his estate an estate for life or for a term of not less than ten years, may execute to the intended transferee a deed or instrument of conveyance in any form authorized by law for that purpose. And upon filing such deed or other instrument in the registrar's office, and surrendering to the registrar the duplicate certificate of title, the transfer shall be complete and the title so transferred shall vest in the transferee; thereupon, the registrar shall issue in duplicate and register, as hereinbefore provided, a new certificate, certifying the title to the estate or interest in the land desired to be conveyed to be in the transferee, and shall note upon the originial and duplicate certificate the date of the transfer, the name of the transferee, and the volume and *folium* in which the new certificate is registered, and shall stamp across the original and surrendered duplicate certificate the word "canceled," in whole or part, as the case may be.

SEC. 49. When only a part of the land described in a certificate is transferred, or some estate or interest in the land is to remain in the transferer, a new certificate shall be issued to him for the part, estate, or interest remaining in him.

Sec. 50. Provides that time of filing be noted on instrument.

Sec. 51. Provides that papers filed are to be retained in the office of registrar.

Sec. 52. Provides that such copies are to be received in evidence.

Sec. 53. Provides that existing forms of deeds may be used.

Sec. 54. Provides that name and address be indorsed on instrument, and notices to be sent there.

Sec. 55. Provides that instrument affecting registered land is to be but a contract until registered.

Sec. 56. Provides that certificate before re-transfer, etc., must show freedom from tax sale and homestead.

Sec. 57. Provides that certificate is to state marriage or representative capacity, if any.

MORGAGES, LEASES AND OTHER CHARGES.

Sec. 58. Provides that incumbrance on registered land must be registered.

Sec. 59. Provides that incumbrance is created on filing of charge.

Sec. 60. Provides for trust deed to be treated as a mortgage.

Sec. 61. Provides that if instrument charging land be in duplicate or more parts, but one need be filed.

Sec. 62. Provides that certified copies identified as such may be issued.

Sec. 63. Provides for assignment of charge by filing and noting of same by memorial.

Sec. 64. Provides for release of part or whole of charge to be noted as an assignment.

Sec. 65. Provides that charges are to be enforced as at present, except as herein provided and except that notice of lis pendens must be filed with registrar.

ATTORNEYS IN FACT.

Sec. 66. Provides that attorney in fact to deal with registered land must file his power.

TRUSTS, CONDITIONS AND LIMITATIONS.

Sec. 67. Whenever a deed or other instrument is filed in

the registrar's office for the purpose of effecting a transfer of, or charge upon, registered lands, or any estate or interest therein, and it appears from such instrument that the transfer or charge is to be in trust, or upon any condition or limitation therein expressed, the registrar shall note in the certificate, and the duplicate thereof, or memoral, the words "in trust," or "upon condition," or "with limitations," as the case may be, but no entry shall be made of the particulars of any such trust, conditions or limitations.

Sec. 68. Provides that every trustee with express authority, shall have power of sale.

Sec. 69. Provides that no trustee, with limitation, shall sell without order of court to sell.

Sec. 70. Provides that trustee under will have power to sell unless it be withheld.

ESTATES IN PROBATE, IN INSOLVENCY, AND IN EQUITY PROCEEDINGS.

Sec. 71. Provides that existing statutes governing probate, insolvency, and equity proceedings are not affected.

Sec. 72. Provides for orders of sale, decrees of distribution, etc., to contain direction to registrar.

Sec. 73. Provides that certified copy of order, decree, deed, and confirmation be filed with registrar.

Sec. 74. Provides that order of court is necessary for sale of land of insolvent and probate estates; confirmation and issuance of certificates thereof.

Sec. 75. Provides that power of sale of executor be noted.

Sec. 76. Provides that registrar is to issue certificate or note memorial, such to be conclusive.

TAX SALES.

Sec. 77. Provides for notice of purchase to be filed and mailed.

Sec. 78. Provides that tax deed already issued must be registered.

Sec. 79. Provides that interested persons must be made parties to application.

Sec. 80. Such application shall be heard by the court, which shall render a decree showing the condition of the title to such land, and who is the owner thereof, and upon presentation to him, of a duly certified copy of such decree, the registrar shall issue a certificate for said land in accordance with the terms and conditions of said decree.

Sec. 81. Provides that tax deed to State is conclusive.

Sec. 82. Provides that notice required by section eighty shall be personal or by mail and publication.

Sec. 83. Provides that on redemption, memorial is to be canceled.

PARTITION AND JUDICIAL SALES.

Sec. 84. Provides that all parties noted on register must be parties.

Sec. 85. Provides that decree must be filed before certificate be issued.

Sec. 86. Provides that when sale is ordered, purchaser must file copy of decree.

Sec. 87. Provides that when mortgage is on undivided share, lien attaches only to lands set off to mortgagor.

Sec. 88. Provides that purchaser at judicial sale must file certified copy of order confirming sale.

LIS PENDENS: NOTICE OF ACTION.

Sec. 89. Provides that notice to affect registered land must be filed with registrar.

Sec. 90. Provides that when suit, etc., is dismissed, certificate of dismissal or release must be filed with registrar.

LIENS, EXECUTIONS, ATTACHMENTS, ETC.

Sec. 91. Provides that certified copy of judgment or decree must be filed.

Sec. 92. Provides that certificate of levy of attachment, or execution, must be filed.

Sec. 93. Provides that notice of mechanics' liens must be filed.

Sec. 94. Provides that notice of assessments for street improvements, sewers, etc., must be filed by clerk.

Sec. 95. Provides that no notice is necessary is case of lien for labor performed for corporation not complying with law.

Sec. 96. Provides that clerk of court may file certificate of dismissal of suit or satisfaction of judgment.

CORRECTIONS OF ERRORS IN CERTIFICATE.

Sec. 97. Provides that no correction of register be made without order of court.

Sec. 98. Provides that registrar may apply to court for correction of errors or mistakes in certificate.

Sec. 99. Provides that if all parties consent, court may order correction of errors or mistakes.

Sec. 100. Provides that if all parties do not consent, court may hear testimony as to alleged error or mistake.

EMINENT DOMAIN.

Sec. 101. Provides that right of eminent domain be not affected.

INDICES.

Sec. 102. Provides for property indices to be kept.

Sec. 103. Provides for name indices to be kept.

MISCELLANEOUS PROVISIONS.

Sec. 104. Provides that registered lands may be partitioned.

Sec. 105. Provides that registration of adverse lien is not conclusive of regularity of proceedings or instruments by which created.

Sec. 106. Provides that in case of fraud, rights and remedies to be the same as if land was not under this Act.

Sec. 107. Provides that clerk of court shall notify registrar of appeal.

Lection 108. Provides that all fees collected by registrar are to be paid to County Treasurer and applied to expenses of administration of this Act.

Sec. 109. Provides that Board of Supervisiors shall furnisher registrar all necessary books, etc.

Sec. 110. Provides that the Attorney-General, State Controller, and Secretary of State are to prepare forms.

PENALTIES.

Sec. 111. Provides that fraudulent procurement of certificate shall be a felony.

Sec. 112. Provides that fogery of seal, signature, or instrument in registrar's office shall be a felony.

Sec. 113. Provides that no proceeding or conviction under this Act shall affect any remedy at law or in equity.

FEES.

Sec. 114. *First*—The fees in respect of applications and proceedings under them prior to registration, shall be the same as in actions in the Superior Court.

Second—There shall be paid to the registrar:

For issuing a certificate title, including one duplicate thereof, one dollar and fifty cents.

For each additional duplicate, fifty cents.

For registering each transfer, including the issue and registration of the new certificate, one dollar and fifty cents.

For entry of each memorial on the register, including the indorsement upon the duplicate certificates, one dollar.

For the cancellation of each certificate, memorial, or charge twenty-five cents.

For each certificate showing condition of register, one dollar and fifty cents.

For filing any instrument, or for a certified copy of the register, or of any instrument or writing on file in his office, the same fees allowed by law to Recorders for like services.

CONSTRUCTION.

Sec. 115. This Act shall be construed liberally so far as may be necessary for tho purpose of effecting its general intent, but does not adopt by implication the construction of any similar legislation of other jurisdictions which this Act may to any extent have followed.

Sec. 116. This Act shall take affect and be in force from and after the first day of July, eighteen hundred and ninety-seven.

BOOKS AND PERIODICALS.

Ray's Recruit by Captain Charles King, U. S. A., is the complete story in LIPPINCOTT'S MAGAZINE. Everybody who read one of Captain Kings' novels will want to read it so the demand for the magazine should be large, as besides this story the contents are unusually interesting.

Improvement in building construction—mainly relating to Portland Cement, Concrete and Artificial Stone combined with Iron and Steel—by Peter H. Jackson.

This brochure contains an illustrated account of the latest improvements in fireproofing floor construction.

The first construction considered is that called the combined artificial stone and steel sidewalk, in which the roof of the vault consists of galvanized steel corrugated bottoms covered with a thin layer of artificial stone thoroughly tamped into the corrugations which are of dovetail shape—the whole not taking up a greater thickness than three inches. This construction at this thickness can be made up to 5 feet span between beams, center to center, 3¾ inches for 6 feet centers and 4½ inches for 7 feet centers.

The advantages claimed are great strength, burglar and fireproof and greater head-room gained by thinness of floor, while the cost is no greater than the common method.

In direction across the corrugation are embedded in the artificial stone, fence twisted wires which tie the floor in opposite direction to corrugation, and prevents cracking—due to shrinkage. For all this Mr. Jackson offers scientific and cogent reasons.

Complete specifications for this constructions is given in the body of the work, as well as for sidewalks combined with arches either flat or segmental and concrete floors in which reliable ties are used.

Part second treats of the forces exerted on such floors as the latter, and the manner in which reliable ties in concrete construction resist tensile strain.

The book is replete with interesting matter well worth the study of the architect and engineer and is written in the terse nervous style so characteristic of Mr. Jackson. It forms quite an ammunition for those who are defending concrete construction against its enemies.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects; meets second Friday of each month at 408 California street.

Seth Babson, Pres. — W. P. Moore, Vice-Pres.
Oliver Everett, Sec. — John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Theo. A. Eisen, Pres. — Arthur B. Benton, Vice-Pres.
William C. Aiken, Sec't. — August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

Jos. C. Hornblower, Pres. — Jas. G. Hill, Vice-Pres.
E. W. Dunn, Jr., Sec. — W. J. Marsh, Treas.

Association of Architects of Arizona, meetings held at Phoenix, Arizona.

D. W. Millard, Pres. — T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

E. J. Molera, Pres. — W. F. C. Hasson, Vice-Pres.
Otto Von Geldern, Sec. — Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. — J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

Oscar Lewis, Pres. — Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. — M. V. Brady, Sec.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

FIRST PRESBYTERIAN CHURCH, Berkeley, Sam'l Newsom, Architect.

SKETCH for Residence in Brick and Stone Trimmings, for O. D. Baldwin, Sam'l Newsom, Architect.

ACME ATHLETIC CLUB BUILDING, Oakland, Charles Mau, Architect.

I. O. O. F. COLUMBARIUM, Cahill & Condon, Architects.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

BUILDING RESTRICTIONS IN DEED OF CONVEYANCE.—Where lots have been conveyed subject to a convenant that no buildings shall be erected on the same within a certain distance of the street, such convenant is enforceable, though the streets on which such lots abuts has changed from a residence street to a business street.

Zipp v. Barker, Sup. Ct. App. Div., 40 N. Y. Supp. Reporter, 325.

ENCROACHMENT OF BUILDING.—Where a contract for the sale of real estate provides for a variance in the dimensions of the premises of one inch in width and depth, the purchaser will be relieved from the contract if the building on the premises encroaches more than one inch on the adjoining premises.

Steckler v. Godillot, City of N. Y. Court, 40 N. Y. Supp. Rep. 864.

BUILDING CONTRACT AND SECURITY BOND.—Where there is a sufficient reference in the bond given to secure the performance of a building contract, the reference makes all the stipulations of the contract a part of the bond, and they may be read together without a recital in the bond that the contract was a written one.

Forst v. Leonard, Sup. Ct. Ala., 20 Southern Reporter, 587.

MATERIAL MAN:—The Supreme Court of California holds that one who agrees to furnish certain mantels, tiles and grates, and the appurtenances of same, for a building, and to deliver and set them in position, is a material man, and not an original contractor within the meaning of the mechahics' lien law of that state.

Bennett v. Davis, 45 Pacific Reporter. 684.

MATERIAL MAN:—The same court also holds, a person contracting to furnish doors, sashes, blinds, etc., which I facturing to order, he purchased ready made, is a material man only.

Wilson v. Hind, 45 Pacific Reporter, 695.

ARCHITECTURE OF THE NINETEENTH CENTURY.

THE best that can be said of the architecture of the nineteenth century is that it has been an architecture of exceptionally learned, ingenious, and accomplished individualities. It has been an art of experiments which have failed, and of revivals which have been fruitless. These individualities, with their consciousness highly educated and trained, have been embarassed rather than aided by their knowledge of the great achievements of the past. It does not seem to have occurred to them to appeal to the sympathies of the people by uttering their inspirations in the vulgar tongue, but they have labored with immense talent and ingenuity to interpret and apply dead languages. Their efforts have been reminiscent, excursive, and experimental. The architects have analized, theorized, disputed and argued. They have formed schools, canserving classic or romantic traditions—schools which have fallen apart, because progress has been found to be impossible on merely archæo logical lines. Many of the individualities developed under these conditions have been brilliant and powerful, and have had a great following of lesser men. As the century has advanced certain of these individualities have been inspired by nobler and loftier motives. The architecture of the century, because it has been nurished in the same soil that produced the electric telegraph, the telephone, and all the other triumphs of industrial art, has exhibited a certain sporadic vitality, and, conscious of the universal energy, has occasionally thrown out mighty branches full of the possibilities of a great fruition; but, because it has not enjoyed the advantage of concentrated effort, it has not flowered as it flowered in the thirteenth and sixteenth centuries, still less as it flowered in the ages of Periclos and Agustus.—*Henry Van Brunt in the February Atlantic.*

BUSINESS MOSAICS.

Before you decide what plumbing to have in your new house call upon M. S. James, room 27 Flood Building, and examine what he has to show you in the way of bath tubs, kitchen sinks and the various appliances in this line for producing health and comfort in your dwelling. Mr. James is the Pacific Coast representative of The J. L. Mott Iron Works, established in 1828 and well known all over the United States as leader in improvements in the way of making your home comfortable.

Tommy—Paw, what is a designing villian? MR. FIGG—Oh, the description would apply to one of these carpenter architects about as well as anything.

Architects are well informed of the merits of the articles manufactured by the P. & B. Paraffine Paint Co., but it may be well to call the attention of those who are their own architects, and therefor perhaps not so well posted as to the merits of their paint, building paper and roofing. and assure them they cannot go wrong if they order what they want in that line from this reliable firm at 116 Battery street, San Francisco, Cal.

Magistrate—You're charged with stealing some diamond studs. Have you anything to say? PRISONER—Well, yer worship, the card on which was the studs was marked "collar studs," so I took it as an invitation an' did collar 'em.—*London Fun.*

Now that the season of hot weather is coming it is time to look at Hill's Patent Sliding Blinds; instead of being blind and going some place else call on Edward B. Hindes & Co., 411 Mission street and get the newest blind made.

Dunham, Carrigan & Hayden Co., 17-19 Beale St. An illustration of their American Sliding Door Hanger for which they claim unusual advantages is given upon page ix of this journal. The company also sell the Yale & Towne Manufacturing Co. celebrated Yale Locks. In this connection it may be interesting to know that originally this line of locks comprised but seven varieties now has expanded to embrace upwards of three hundred different locking devices, from a large front door lock to the smallest cabinet lock, and from a massive prison lock to a diminutive padlock.

"It is indeed hard," said the melancholy gentleman, "to lose one's relatives." "Hard?" snorted the gentleman of wealth; "hard? It is impossible."—*Figaro.*

In nothing is the house holder more apt to be imposed upon than in paint, therefore a few facts upon paint from a reliable source should be of great value; W. P. Fuller & Co. are competent to give the information upon this point, they say: To make perfect paint the material must be pure and finely ground and throughly mixed with heavy machinery. The Phœnix paint is made in this way.

Sarcastic BARBER (pausing in the mutilation)—Will you have a close shave, sir? VICTIM—(with a gasp)—If I get out of this chair alive, I shall certainly consider it such.—*Omaha Bee.*

George Goodman patentee and manufacturer of artifical stone in all its branches; this stone speaks for itself and is its own recommendation—307 Montgomery street, Nevada Block, San Francisco.

CITY BUILDING NEWS.

Baker near McAllister. Cottage; owner, Peter Schenkel; architect, J. L. Frank; contractor, R. Trost; signed, March 16; filed, March 18; cost $3318.

Beal near Bryant. To build; owners, Hobbs, Wall & Co.; architect, T. J. Welsh; contractor, Pacific Refining and Roofing Co.; signed, March 19; filed, March 23; cost $1050.

Bernard near Jones. To build; owner, Mrs. Susan Underwood; architect, C. M. Rousseau; contractor, W. R. Kenny; signed, March 29; filed, April 1; cost $1950.

Bush and Battery. Alterations; owner, Lewis Meyerstein; architect, E. R. Swain; contractors, L. and E. Emanuel; signed, March 16; filed, March 19; cost $2852.

Bush and Battery. Elevator; owner, Isabella Clark, et al; architect, E. R. Swain; contractor, W. L. Holman; signed, March 26; filed, April 2; cost $2890.

Bryant Ave. Two-story frame; owner, W. Fairgneeve; architect, G. H. Batcheldor; contractor J. Bucher; signed, April 6; filed, April 7; cost $2300.

California near 3d Ave. To build; contractors, Petterson & Person; signed, March 29; filed, April 1; cost $2150.

California Ave. near Virginia Ave. Two-story frame; owner, Mrs. W. Byrnes and Mrs. A. Byrnes; contractor, Alex. O. Brown; signed, April 2; filed, April 7; cost $1806.

California and Leidesdorff. Addition and alteration; owner, Nathan Mayer, Baron Rothschild, et; architects, Pissis & Moore; conractor, F. W. Kern; cost $38,500. Stone work; contractor, J. D. McGilvry; cost $8297. Plumbing, etc.; contractor, E. J. Duffey; cost $3650. Electrical work; contractor, California Electric Works; $1108. Heating, etc.; contractor, Geo. H. Tay & Co.; cost $ 1520. Paining; contractor, J. St. Dennis & Co.; cost $1448.

California near Laguna. Additions and alterations; owner, R. J. Wilson; architect, W. J. Mathews; contractor, J. A. Smillie; signed, April 13; filed, April 14; cost $2100.

Central Ave. near Waller. To build; owner, Edward J. Duffey; contractor, J. J. Mauseau; signed, March 28; filed, March 28; cost $2944.

Devisadero near Post. Three-story frame; owner, W. C. Hays; contractor, B. R. Van Deusen; signed, April 3; filed, April 7; cost $12,500.

Devisadero street. Three-story frame; owner, M. Block; contractor, H. P. Conrady; signed, April 8; filed, April 8; cost $6650.

Eighth Ave. near C. To build; owner, R. H. Savory; contractors, Marcuse & Remmel; signed, March 23; filed, April 5; cost $2000.

Eighteenth and Dolores. Heating and ventilating Works; owner, Board of Education; architect, C. I. Havens; contractors, Peck & Williamson Co., signed, March 12; filed, March 19; cost $9120.

Eleventh Ave. near J. Cottage; owner, Howard Hines; contractor, Ed. Cox; signed, April 10; filed, April 12; cost $1380.

Fell near Fillmore. To build; owner, Mrs. C. L. Purlenky; architect, P. Schwerdt; contractors, Wilhelm & Taylor; signed, March 25; filed, March 26; cost $3890.

Fell near Fillmore. Plumbing; owner, Mrs. C. L. Puolenky; architect, P. Schwerdt; contractors, Hughes Bros.; signed, March 26; filed, March 30; cost $575.

Fifth street, No. 438. Removal of building back new building in front; owner, Mr. Judson; day's work; cost $4000.

Filbert near Webster. Cottage; owner, John Marchi; architect, Jules Godart; contractor, C. M. Depew; filed, March 18; cost $1698.

Fremont near Mission. Two-story brick; owner, Thomas Breen; architect, D. C. Coleman; contractor, M. V. Brady; signed, March 20; filed, March 22; cost $4977. Excavation and concrete; contractor, J. Leonard; cost $2500.

Fifteenth Ave. near California. Cottage; owner, John McDonald; contractor, M. J. Scott; signed, March 22; filed, March 23; cost $1050.

Fulton near Masonic Ave. Two-story frame; owner, Margaret A. Martin; contractor, Chas. Mills; signed, March 11; filed, April 2; cost $2950.

Fourth and Welsh. To build; owner C. B. Rode; architect, C. M. Rousseau; contractor, R. J. Pavert; signed, April 5; filed, April 6; cost $3104.

Geary near Larkin. Alterations and additions; owner, Esther Attell; architects, Bowpsmith & Whitaker; contractor, D. R. Perry; signed, March 22; filed, March 23; cost $1540.

Geary near Broderick. To build; owner, John F. & Matilda Krutmeyer; architect, R. H. White; contractors, Petterson & Person; signed, March 30; filed, Apr. 11; cost $1763.

Greenwich near Fillon. To build; owner, G. L. Keller; architects, Mahoney & Bryant; contractor, C. Kroeker; signed, March 22; filed, March 24; cost $3400.

Greenwich near Octavia. To build; owner, W. C. Miller; contractors, Sarconda & Thompson; signed, March 22; filed, April 4; cost $1235.

Harrison near 24th. To build; owner, Mary C. Collins; architect, D. C. Coleman; contractor, John T. Coleman; signed, March 20; filed, March 20; cost $[illegible].

Howard near Fremont. Two-story brick; owner, Christian Fraelich; architect, Arthur Sutton; contractor, Shaw & Lane; signed, March 30; filed, March 30; cost $[illegible].

Jackson and Taylor. Three-story frame; owner, D. V. Buckley; architect, B. J. Leach; contractors, Shaver & Hughes; signed, April 5; filed, April 6; cost $[illegible].

Lake near 23d Ave. Cottage; owner, Clothilda Capapa; architect, H. Hess; contractor, [illegible] Geoghegan; signed, March 27; filed, April 6; cost $1610.

Laguna near Page. Two-story frame; owner, Joseph Hoene; contractor, C. Zauderich; signed, Frederick; filed, March 16; cost $1450.

Larkin near Jackson. Plumbing, etc; owner, W. Buchanan; architect, L. T. Larkin; contractor, P. Doherty; signed, March 26; filed, March 27; cost $418. Stone, cement and concrete; Doherty; signed, March 26; filed, March 27; cost $418. Carpentry; painting, etc., contractor, F. Miller; signed, March 20; filed, [illegible]; cost $2280.

Larkin near Jackson. Three-story frame; owner, Mrs. Nora Wallace; architects; Mahoney & Bryland, contractor, T. Haywell; signed, March 24; filed, March 24; cost $3885.

Larkin near Sacramento. Two-story frame; owner, Mrs. Sarah Potek; architect, Kemtzer & Barth; contractor, C. Schutt; signed, April 9; filed, April 13; cost $3780.

Lampet near Fillmore. Alterations and additions; owner, Michael McIntyre; architect, M. J. Welsh; contractor, R. Fahy; signed, April 9; filed, April 10 cost $1032.

Leavenworth near McAllister. One-story brick; owner, Mr. Grimm; contractor, H. Sutton; cost $800.

Liberty near Castro. Eight frame dwellings; owner and builder; F. Nealon; cost $20,000.

Lombard near Gough. Cottage and stable; owner, John Bazzini; architect, J. Godart; contractor, P. A. Piombelli; signed, April 12; filed, April 12; cost $2497.

Lyon and Grove. Three two-story dwellings; owner, F. Ruthland; contractor, C. Zwierlein; signed, March 17; filed, March 18; cost about $8000.

Market and Third. Terra cotta, etc., for eight-story brick; owner, Phebe A. Hearst; architect, A. C. Schweinfurth; contractors, Gladding, McBean Co.; signed, March 11; filed, April 14; cost $17,760. Roofing; contractor, Jas. Conlin; signed, April 10; filed, April 14; cost $1175.

Market and Third. Granite work; owner, Phebe A. Hearst; architect, A. C. Schweinfurth; contractor, Raymond Granite Co; signed March 17; filed, March 20; cost $8525.

Market and Third. Cast iron work; owner, Phebe A. Hearst; architect, A. C. Schweinfurth; contractor, Joshua Hendy Machine Works; signed, Feb. 25; filed, March 17; cost $3620.

Market and Third. Plastering iron lathing, etc.; owner, Claus Spreckels; architects, Reid Bros.; contractor, Thomas Mannix; signed, March 26; filed, April 9; cost $10,986. First-story window frames, etc.; contractor, California Artistic Metal Works; signed, March 31; filed, April 8; cost $62,590. Elevators; contractor, Crane Elevator Co; signed, March 17; filed, March 27; cost $32,350.

Market and Third. Interior wood work, etc.; owner, Claus Spreckels; architect, Reid Bros.; contractor, Carsley Manufacturing Co.; signed, March 5; filed, March 20; cost $66,310. Steam heating; contractors, Montague & Co.; cost $67,0. Marble and mosaic floors; contractor, Electric Electric Works; cost $15,373. Marble work; contractor, Ratlino & Bianchi; cost $20,468. Plumbing; contractor, E. J. Duffy; cost $22,416.

Minna near Sixth. Alterations and additions; owner, Little Sisters' Infant Shelter; architect, Oliver Everett; contractors, Holm & Shelbley; signed; March 30; filed, March 30; cost $202.

Market and Third. Concrete work, etc.; owner, Phebe A. Hearst; architect, A. C. Schweinfurth; contractor Geo. Goodman; signed, March 31; filed, April, 2 cost $3700.

Mission near 23d. Heating and ventilation; owner, Mission Lodge, Masonic Assn.; architects, Herman & Swain; contractor, W. Morgan & Co.; signed; April 6; filed, April 7; cost $866.

Mission near 23d. Brick and terra cotta work; owner, Mission Lodge; architect Herman & Swain; contractors, Miller & Beck; signed, March 23; filed, March 23; cost $8855. Carpenter work; contractor, Thomas H. Day; signed, March 23; filed, March 23; cost $8800. Plumbing, etc.; contractor, W. S. Snook & Son; signed, March 24; filed, March 24; cost $1147.

Nevada Ave. near Courtland Ave. Cottage; owner, J. Heyman; cost $1200.

Nineteenth Ave. near California. Alterations; owner, M. Barker; cost $800.

Nineteenth and Noe. To build; owner, Jos. H. Robinson; contractor, John Dyer; signed, March 28; filed, March 29; cost $4750.

Ninth Ave. and Railway Ave. To build; owner, G. Reichstetter; architect, J. L. Frank; contractor, R. Trost; signed, April 8; filed, April 12; cost $4957.

Ocean Beach Bulevard. Additional story to Villa; owner, R. H. Savary; contractors, Marcuse & Remmel; signed, March 23; filed, April 5; cost $2000.

Pacific Ave. and Broderick. Alterations; owner, Mrs. Clara E Cunningham; architect, Clinton Day; contractor, C. Chisholm, signed, April 8; filed, April 6; cost $2260.

Powell near O'Farrell. Alterations and additions; owner, Mrs. Kenie Chabot; architect, M. J. Mathews; contractor, P. Malony; signed, April 5; filed, April 9; cost $4975.

Powell street No. 13. Alterations and additions; owner, Mrs. Charlotte Clark; architects, Havens & Toepke; contractor, Geo. H. Walker; signed, March 22; filed, March 24; cost $4600.

Pine near Lyon. Cottage; owner, Mrs. Annie Loughery; contractor, G. S. Gillespie; signed, April 5; filed, April 6; cost $1350.

Second Ave. near Clement. To build, owner, W. J. Kilday; architect, A. J. Barnett; contractor, Ed. Mooney; signed, April 8; filed, April 12; cost $1570.

Shrader near Beulah. To build; owner, Nellie E. Scott; contractor, W. W. Redmall; sined, April 8; filed, April 9; cost $2642.

Sixth Ave. near Pt. Lobos. To build; owner, C. B. de Pas; architect, E. Deplerre; contractor, Ira W. Coburn; signed, April 7; filed, April 7; cost $1940.

Sixteenth near Castro. Alterations and additions; owner, C. W. Eichbaum; architects, Copeland & Pierce; contractor, J. J. Doering; signed, April 6; filed, April 10; cost $1150.

Stockton near Clay. Two-story brick; owner, Jas. Goetz; architect, T. J. Welsh; contractor, D. J. Brannan; signed, March 30; filed, April 1; cost $4825. Carpentry work; contractor, A. L. Campbell; cost $1984.

Sutter near Jones. Electric elevator; owner, Henry Kohler; architect, H. Gellfuss; contractor, Cahill & Hall Elevator Co; signed, March 12; filed, March 12; cost $3285.

Sutter near Hyde. Elevator; owner, Dr. Julius Rosenstern; architects, Salfield Kohlberg; contractor, W. L. Holman; signed, March 3; filed, March 19; cost $2550.

Tehama near 4th. To build; owner, Mrs. E. M. Dumont; architect, J. Godart contractor, L. B. Perramont; cost $1158.

Twenty-first and Folsom. To build; owner, J. Schmidt; architect; H. Gellfuss; contractor, W. R. Jack; signed, April 2; filed, April 2; cost $3300.

Twenty-third near Douglass. Cottage; owner, J. C. Clark; builder, J. Hegman cost $1500.

Twenty-third near Hoffman. Cottage; owner and builder, J. Hegman; cost $2500.

Twenty-third near Capp. To build; owner, Thos. F. Brannan; contractor, W. Helbing; cost $2900.

Twenty-forth Ave. Lake. Additions; owner, F. Treichel; days work; cost $1000.

Union and Laguna. Carpenter work; owner, Adolph Eisenbach; architects, Salfield & Kohlberg; contractor, Jos. Bucher; cost $7150. Plumbing; contractor, H. Williamson; cost $1480. Concrete work; contractors, P. H. Goessel & L. M. Zimmerman; cost $1625.

Union near Webster. To build; owner, Mary Muir; architects, Mooser & Son contractor, A. Guilbert; signed, April 7; filed, April 10; cost $1540.

Vallejo near Polk. Additions; owner, Golden Gate Land Co.; architect, H. Gellfuss; contractor, J. Schuler; signed April 5; filed, April 6; cost $1470.

Valencia near 26th. To build; owner, Henry Hoffman; architect, J. McHenry; contractor, Jos. Kemp; cost $3250.

Van Ness Ave. and Clay. Iron fences, etc; owner, Claus Spreckels; architects, Reid Bros.; contractor, Winslow Bros. Co; cost $3150.

Van Ness Ave. near Bay. Cottage; owner, Frank P. Endlich; architect, C. A. Meussdorffer; contractor, F. V. Steinman; cost $1893.

The California Architect and Building News.

IN ANOTHER column we publish an Amendment to the Mechanics' Lien Law of the State of California, that will be of interest to owners of real estate and all others connected with the building business.

This ammendment was passed by the late legislature and approved March 27, 1897, and imposes additional obligations on those persons who are still enterprising enough to want to improve their real estate holdings.

The intention of the law is good, in endeavoring to make it compulsory on the part of the owner to give the public due notice of the date of the completion of contracts, in order that creditors shall have some certainty in filing their liens. that they have been filed within the statutory time limit.

There has often been serious question about the date of the actual completion of buildings, and if this law helps to determine that point it will be of material advantage to all who honestly desire to comply with the requirements of law, and not avail themselves of technicalities to defeat the plain intention of the law.

However the practical value of the amendment can only be ascertained by actual trial, when any defects that may exist will soon be brought to light. In the mean time owners should make themselves familiar with the new requirements, and not fail to make and file the proper notice of completion.

TENANTS on the site of the proposed Post-office building have been notified to vacate by June 8th, as work on the site will be commenced by the Government by the 1st of July.—*Examiner.*

In the same issue of that paper, but on another page will be found the following dispatch, directly contradictory of the above item:

WASHINGTON, May 9.—Owing to the resignation of Supervising Architect Aiken it is impossible to state just when work will be commenced on the San Francisco public building. Orders have been issued for the dismantling of the buildings now on this site, and plans are practically completed for the superstructure of the new building. Advertisements for bids for excavating will shortly be sent out, according to Chief Executive Officer Kemper of the Supervising Architect's office, and the contract will be awarded within a month after these bids are received. Owing to changes made in the Supervising Architect's office, however, it is impossible to state just when actual work will be commenced.

It is dollars to doughnuts that July 1st will come and go without a visible change in the situation.

The *Call* however, is already patting itself on the back at the prospect of the actual commencement of work on the foundations, as the result of its agitation.

Several years ago it was positively and authoritatively

stated that work would be begun on the "first day of March;" this is what leads us to think that possibly the *Call* is not out of the woods, and that it may yet have to acknowledge the truth of the old adage "there's many a slip twixt cup and lip."

AMENDMENT TO THE MECHANICS' LIEN LAW.

CHAPTER CXLI.—AN ACT TO AMEND SECTION ELEVEN HUNDRED AND EIGHTY-SENEN OF THE CODE OF CIVIL PROCEDURE, CONCERNING THE FILING OF MECHANICS' LIENS.

[Approved March 27, 1897.]

THE people of the State of California, represented in Senate and Assembly, do enact as follows:

Section eleven hundred and eighty-seven of the Code of Civil Procedure is hereby amended so as to read as follows:

1187. The owner of any property on which labor has been performed, or for which materials have been furnished to be used in the construction, alteration, addition to, or repair, either in whole or in part, of any work, mentioned in section eleven hundred and eighty-three of this Code must, within ten days after the completion thereof or within forty days after cessation from labor upon any unfinished contract, or upon any unfinished building, improvement, or structure, or the alteration, addition to, or the repair thereof, file for record in the office of the County Recorder of the county, or city and county, in which such property or some part thereof is situated, a notice setting forth the date when such building, improvement, or structure, or the alteration, addition to, or repair thereof, was actually completed, or in case of cessation from labor for thirty days, the date on which such cessation actually occurred, and said notice shall also contain the name and the nature of the title of the person who caused the said building, improvement, or structure to be erected, or said alteration, addition to, or repair to be made, and also a description of the property sufficient for identification, and said notice must be verified by said owner or some other person in his behalf. In case any such owner neglect to file said notice as herein required, within the time herein required, then the said owner and all persons deraigning title from him, and all persons claiming an interest in said property, shall be estopped in any proceedings brought to foreclose any mechanics' lien or liens, provided for in this chapter, from maintaining a defense therein based on the ground that said lien or liens have not been filed within the time provided in this chapter. Said notice, when so filed for record, must be recorded by the County Recorder with whom the same is filed for record, and the fee for recording the same shall be the sum of one dollar.

Every original contractor, at any time after the completion of his contract, and until the expiration of sixty days after the filing of said notice of completion or notice of cessation of labor by the owner, and every person, save the original contractor, claiming the benefit of this chapter, at any time after the completion of any building, improvement, or structure, or of the alteration, addition to, or repair thereof, and until the expiration of thirty days after the filing of said notice of completion or cessation, by said owner, or within thirty days after the performance of any labor in a mining claim, must file for record with the County Recorder of the county, or city and county, in which such property or some part thereof is situated, a claim containing a statement of his demand, after deducting all just credits and offsets, with the name of the owner or reputed owner, if known, and also the name of the person by whom he was employed, or to whom he furnished the materials, with a statement of the terms, time given, and conditions of his contract, and also a description of the property to be charged with the lien, sufficient for identification, which claim must be verified by the oath of himself or some other person; *provided, however*, that in any event all claims of lien must be filed within ninety days after the completion of said building, improvement, or structure, or the alteration, addition to, or repair thereof. Any trivial imperfection in the said work, or in the construction of any building, improvement, or structure, or of the alteration, addition to, or repair thereof, shall not be deemed such a lack of completion as to prevent the filing of any lien; and in all cases the occupation or use of a building, improvement, or structure, by the owner, or his representative, or the acceptance by said owner or his agent of said building, improvement, or structure, and cessation from labor for thirty days upon any contract or upon any building, improvement, or structure, or the alteration, addition to, or repair thereof, shall be deemed equivalent to a completion thereof for all the purposes of this chapter.

HOUSING OF PEOPLE OF SMALL INCOMES.

No. 7.

BUILDING REGULATIONS CONTINUED FROM FEBRUARY NUMBER.

II. Tests.

THE plumber will test all of the soil, waste, drain, and vent pipes herein described, including branches, in the presence of an inspector of the department of buildings, and after due notice to the superintendent of buildings, by a pressure test; the pressure to be applied as directed by the inspector, and after all openings in the pipes have been securely closed by the plumber or other person in charge of the work. None of said pipes shall be covered until after they have stood the test to the satisfaction of the inspector.

III—CESSPOOLS AND SEWERS.

No cesspools will be allowed where there is a well on the same or adjacent premises, without a special permit from the superintendent of buildings.

The ..... will construct in ..... at ..... feet from the building a cesspool ..... by ..... and ..... deep, with ..... inch ..... walls, and bottom made absolutely watertight by means of ..... The cesspool will be covered with ..... and ventilated by .....

As soon as it is possible to connect above-mentioned house with a public sewer, the owner will have the cesspool emptied, cleaned, disinfected, and filled with fresh earth, and

have such connection made in the manner prescribed by the regulations of the superintendent of buildings.

PRIVATE SEWERS.

Where there is no public sewer in the street, and it is necessary to construct a private sewer to connect with a public sewer in an adjacent street or avenue, it must be laid outside the curb under the roadway of the street on which the houses front, and not through the yards or under the houses. Such sewer will be constructed in the following manner:

HOUSE SEWERS—EXCAVATION.

The ..... will make the necessary excavation for the house sewer from the ..... wall to the ..... sewer in ....., making a smooth bottom for each pipe, free from all projections of rock, and with the soil well rammed to prevent settling of the pipe.

HOUSE SEWER—EARTHENWARE.

[Note.—The laying of earthenware drainpipe for house sewers, in made or filled-in ground, is prohibited by the rules established by the superintendent of buildings. But where the soil consists of a natural bed of loam, sand or rock it is permitted to be laid from outside the cellar, vault, or area wall to the street sewer, if laid in strict compliance with the following directions.]

The ..... will make a separate connection for each building with the ..... sewer by an earthenware pipe ..... inches in diameter, hard and salt glazed, and not less than three-fourths of an inch thick, run at a uniform grade of not less than one-fourth inch per foot, extending the same to a point not less than two feet outside of the outer face of the front cellar, vault, or area wall, as the case may be. Every section will be bedded in cement at the hub. The ends of the pipe will be wetted before apply the cement, and the space between each hub and the small end of the next section will be completely and uniformly filled with the best quality of hydraulic cement, care being taken to prevent any cement being forced into the drain to become an obstruction. No tempered-up cement will be used. A straight edge will be used, and the different pipe sections laid in perfect line on the bottom and sides.

HOUSE SEWER—OR IRON.

Or the plumber will make a separate connection for each building with ..... sewer in ..... by ..... inch extra heavy cast-iron pipe, run at a uniform grade of not less than one-fourth inch per foot, to a point just inside of the ....., cellar, or vault wall, as the case may be.

The house sewer in each case will be connected to the street sewer at a point directly in front of the house for which it is laid.

Old sewers or house drains can be used for new buildings only when found by an inspector of the department of buildings to conform in all respects to the regulations governing new sewers and drains. They will in each case be uncovered for examination by the .....

Notice will be sent to the superintendent of buildings when any sewer or drain pipe herein specified is ready for inspection; and it can be covered only after it has been examined and pronounced satisfactory by an inspector of the department of buildings. In filling the trench no stones will be placed in contact with the pipe, and the earth will be thoroughly packed in without moving the pipe in the slightest degree or starting any of the joints.

IV—HOUSE DRAIN.

The plumber will make a proper connection with the house sewer by extra heavy cast-iron pipe and set a ..... inch extra heavy cast-iron running or half S-strap just inside of the front wall, with a hand-hold for cleaning, covered with a screw cap, properly fitted.

A fresh air inlet of extra heavy cast-iron pipe, not less than four inches in diameter, will be provided and properly connected with the house drain on the inlet side of the house trap, and extended up flush with the sidewalk near the street curb, and properly covered by a galvanized iron grating leaded into the flagstone; or extending to ..... not less than fifteen feet from any door or window, and opening at least twelve inches above finished grade, with cap, bend, or grating.

The ....., will build a ..... box or manhole with ..... cover about the drain trap, so as to make it readily accessible.

The plumber will continue the house drain of extra heavy cast-iron pipe.....inches in diameter, along the cellar wall or ceiling from trap to the point shown on the plan, giving it a uniform grade to the trap of not less than one-fourth inch per foot. The house drain must not be laid beneath the cellar floor, unless the locations of fixtures in the cellar or basement, or the drainage of yards, cellars, or areas requires it to be so laid. Make necessary changes in direction by carved pipes and all connections by Y-branch pipes and one-eight or one-sixteenth bends. From the points shown on the plan, branch pipes of extra heavy cast-iron to be connected with the drain-pipe to receive the soil and waste pipes, the rain-water leader, and the connections from the area, cellar, and yard drains.

All of said branch pipes to be of the diameter hereinafter described and as shown on accompanying plan of cellar drainage.

Where hand-holes for cleaning are provided on the house drain or its branches or their traps, or on the house-drain trap, proper ferrules with screw covers will be used and made gas tight.

V.—SURFACE DRAINAGE, ETC.

All yards, cellars, areas, and light courts will be properly graded by the owner and drained as hereinafter specified. The traps for all such drains will be placed inside the cellar wall and made accessible.

Cellars will not be connected with the house drain unless absolutely necessary, dry cesspools being used where practicable. If connected to the house drain, running traps with cut-off valves and proper water supply will be provided for each connection, as follows:

The ..... will build in each yard, cellar, area, and light court, where shown on plans, a brick cesspool or catch basin, ... by ....., made water tight if sewer connected, and the plumber will set over each a ..... strainer and make connection therewith as specified.

Provide and set where shown on plans ..... inch extra heavy cast-iron yard drain, connecting with house drain and trapped by ..... inch running trap.

Provide and set where shown on plans —— inch area and light court drains, connecting with the house drain and trapped by ..... inch running trap.

If found necessary to prevent dampness, the owner will

ventilates habitable rooms; and where they do not open otherwise to the external air, they must be ventilated by means of a separate shaft, not less than 3 square feet in area, to extend above the roof, and arrange for the admission of light and air at the top in like manner as the shafts for rooms.

WATER-CLOSETS, ETC.

No privy vault or cesspool shall be allowed, if water-closets can be connected with the street sewer. At least one water-closet shall be provided for each two families. The general privy accommodation shall not be placed in the cellar.

YARDS, AREAS, ETC.

Yards, areas, cellars, and light courts shall be properly graded and drained and flagged or concreted.

ALTERATIONS AND ADDITIONS.

No alteration in the light and ventilation of the premises for which this permit is granted shall be made, except upon the express written approval of the superintendent of buildings; nor shall any additional structure be erected upon the lot except upon such approval and a special permit.

_____,

Superintendent of Buildings.

TRANS-MISSISSIPPI EXPOSITION.

OMAHA, May.—A small army of men is now at work on the site of the Trans-Mississippi and International Exposition. Contracts call for the completion of grading within forty days. Meantime the plans of buildings will be perfected. Acting jointly, Walker & Kimball, surpervising architects, and Manager Kirkendall of the Department of Building and Grounds, have awarded the buildings to the following named architects, who will prepare plans:

Agricultural—Cass Gilbert, St. Paul, Minn.
Art—Eames & Young, St. Louis.
Electricity and Machinery—Dwight Perkins, Chicago.
Mines and Mining—J. J. Humphrey, Denver, Colo.
Manufactures and Liberal Arts—S. S. Beeman, Chicago.
Spectatorium—Fisher & Laurie, Omaha.

The architects will begin work upon plans at once.

The most imposing feature of the exposition of 1898 is to be the mineral exhibit. It is proposed to set apart a portion of the grounds for this purpose under the designation of Eldorado, in which a silver palace is to be the central structure. The building as proposed by Mr. S. S. Beman of Chicago, one of the architects of the World's Fair buildings, is to be about 450 feet square, and its title, "Silver Palace," signifies the character of the exhibit to be made in it. It is to be built of metal and silver plated.

It seems very appropriate to select a highly ornate Gothic style of architecture for this building, as this style lends itself readily, with its pinnacles, arches, flying buttresses and graceful and delicate forms, to the idea usually associated with silver art work. Milan cathedral has been referred to by the poet as "Frozen Music," and the sentiment is fully justified by the exquisite grace and lace-like effect of its forest of pinnacles, flying buttresses and statuary. It was from this architectural fountain that the inspiration for the Silver Palace design was drawn.

If one can picture in his mind the fairy-like effect of silvered pinnacles, crockets and points presenting a forest of spires to the silver moon or the golden sun for their reflecting and dancing scintillations, a faint idea of the character and novelty of the possibilities of this beautiful idea can be had. It lies only in the province of the poet to adequately describe the bewildering beauties and glories of this Fairy Palace. Truly the possibilities of effects to be here realized are illimitable.

Generally speaking the plan of the building may be described as a perfect square, surrounded by open arcades and loggias at each story similar to the Venetian palaces. The corners are marked by octagonal towers, terminating with spires and pinnacles. These lower towers will each be 140 feet high.

The crowning glory of the palace will be the central lantern or spire, which will be 250 feet high and octagonal in form, and 100 feet in diameter. This lantern is located in the center of the palace, and is to be roofed with glass. Wide avenues will traverse the floor, at the intersection of which will be placed this lantern, access to which will be had by means of elevators. These avenues will be lofty and beautiful in their cathedral-like proportions and lightness. They are to be covered with glass. In the center of each of the four square courts will be a lantern, or dome covered with glass.

The possibilities of the elestrical illuminations are inexhaustible, and colored and flickering lights may top the pinnacles and illuminate the crockets, and outline the graceful curves of the flying buttresses. It is proposed to house the various silver interests in this palace fully illustrating the silver idea from the mining and smelting to the illimitable ramifications of the arts, the industries and finance.—*The Omaha Daily Bee.*

IN STREETS AND PAPERS.

I HEARD a capital story of a young architect the other day which introduced a rather novel incident on the well-worn subject of the mother-in-law, and showed that, at times architects have certain advantages over ordinary folk. This young man, it appears, had decided that the epoch in his existence had arrived at which he should take unto himself a wife. Preliminaries were arranged with the lady, and as a further step in advance a house was begun for the young couple at a point sufficiently remote from civilization to be agreeable and retired.

Everything went along swimmingly until the hard times struck these United States, and the young man found himself with a greater contact on his hands than his funds permitted. Not unnaturally, being his own client, work was gradually brought to a standstill on the mansion, until a solitary workman represented the architectural activity in that place that once had been such a hive of art and industry.

Meanwhile the marriage had been postponed from time to time on the very obvious grounds that the house was not yet finished; clearly, if the young people had no place to go to, marriage was out of the question. This went along for some time until Mama-in-law-that-was-to-be, who luckily resided

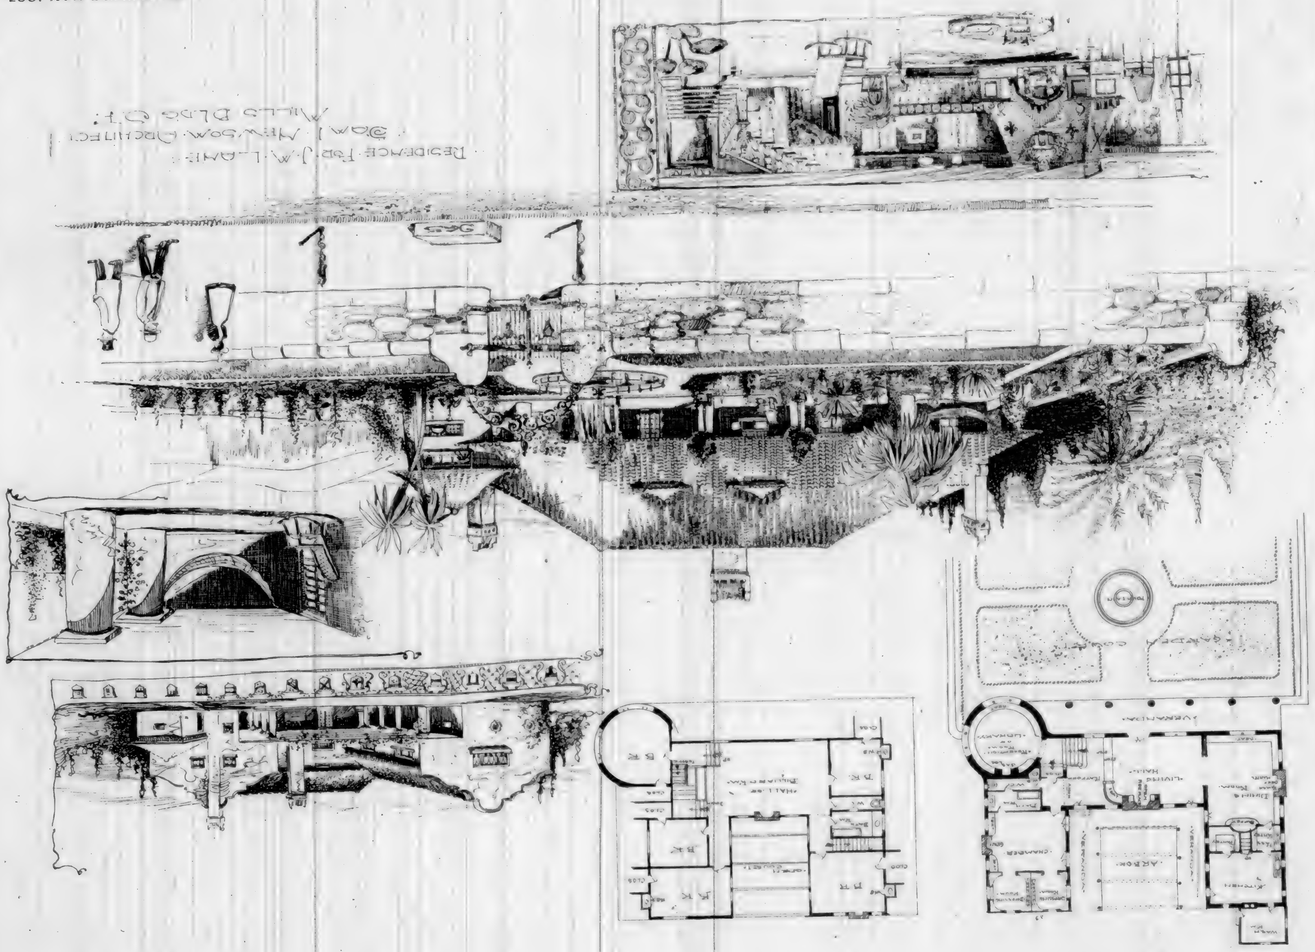
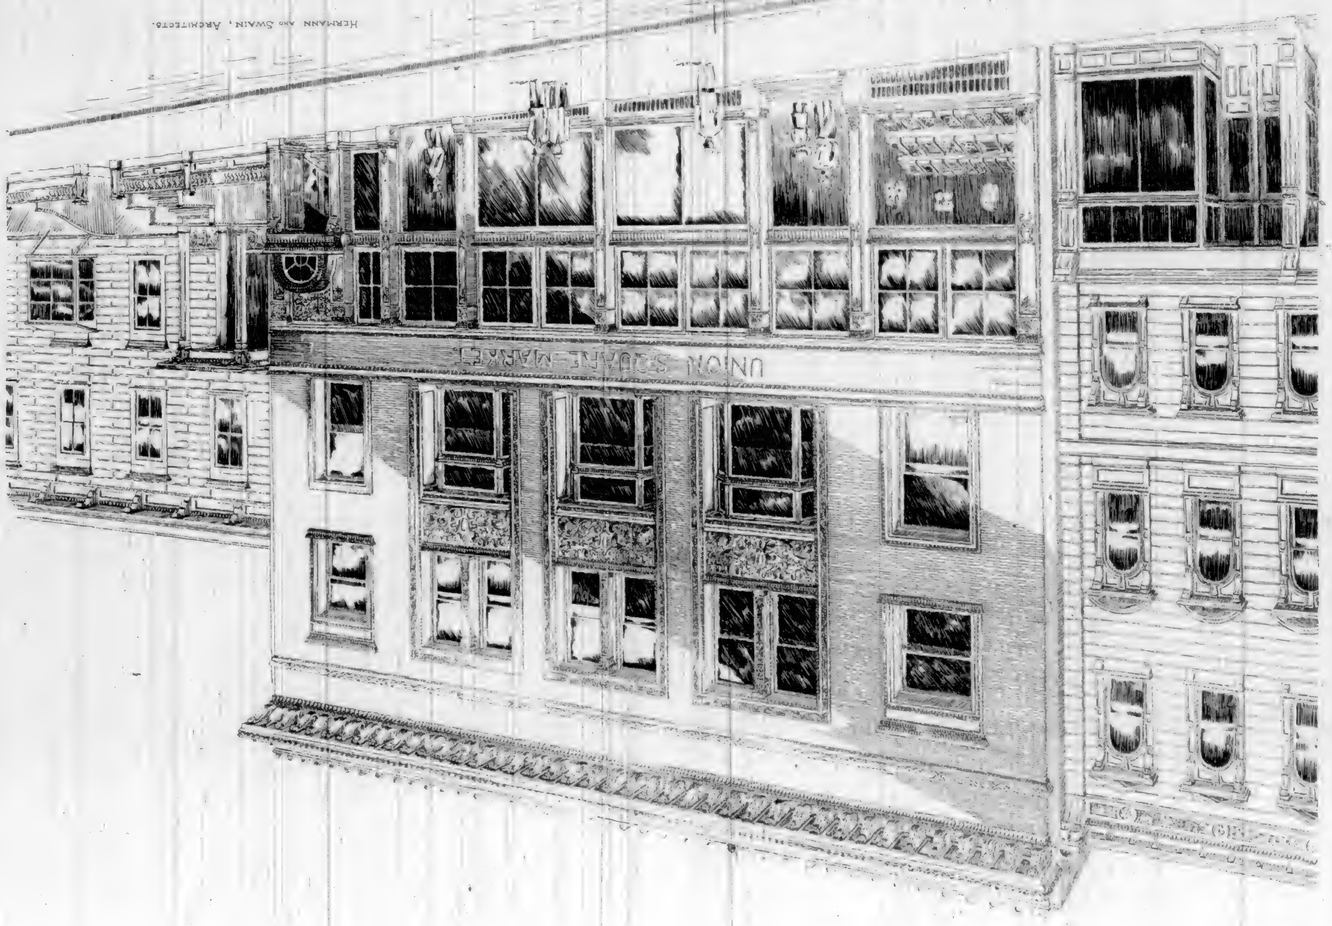
MILLS BLDG. S.F.



HERMANN AND SWAIN, ARCHITECTS.



some hundreds of miles distant from the scene of architectural operations, arrived on the spot to personally investigate into the cause of the delays which were somewhat protracted by this time. To an ordinary man the juxtaposition of a Mother-in-law-that-was-to-be, and an unfinished house containing one (1) laboring man, was an event that savored strongly of a catastrophe. But architects are men of resource, and our youth was no exception to the rule. He bethought himself of the somewhat ordinary circumstance that workingmen have a habit of ceasing from their labors at a definite and appointed time, and never, under any circumstances whatsoever, continuing to labor beyond it. Fortunately, also, the new residence was so remote from everywhere that Mama-in-law-that-was-to-be could scarcely venture to get to it alone. Son-in-law-that-was-to-be therefore impressed upon Mama-in-law-that-was-to-be that he would be only too delighted to take her to his new house any time she wished, and if she would let him know when she wanted to go, he would regard it as the special joy and felicity of his life to take her to see it. At the same time he arranged that his engagements would be such that it would be impossible for him to leave his office until quite late in the afternoon, and so it is easy to perceive that each time Mama and he Son visited the new dwelling they did so after the workmen had gone home.

During the investigating tour of Mama-in-law-that-was-to-be several joint trips were made to the new domicile, but, to this day, the good lady has not discovered that, during the whole time of her stay, only one man was employed on the house, and that, therefore, there was a very obvious reason for the delays in its completion.—*Architecture and Building*.

ARCHITECTS' COMPENSATION.

THE undersigned architects being constantly invited by those not conversant with architectural practice to participate in competitions upon conditions with which it is impossible to comply—announce that they have mutually agreed that they will enter into competition upon the following terms only:

That in any case the undersigned shall be paid at least a sufficient sum to reimburse them for their cash outlay in preparing their competition drawings.

That in case of limited competition the number of competitors shall be definitely named and that the number shall not be increased without the consent of all competitors.

That it shall be definitely understood that the ordinary fees as published by the American Institute of Architects shall be paid as compensation for his professional services to the successful competitor.

That in work of any serious importance a professional advisor or advisors shall be appointed to act with the party instituting the competion in the preparation of a proper programme, which shall be definite in its specifications of requirements, and explicit in its statement of the drawings required, and their character, and of the various rules which shall govern the competition.

In the openion of the undersigned it is very desirable that the professional advisor or advisors should be practicing architects; and the undersigned suggest that the best result can be gained by first appointing the architects to compete and by inviting them to meet with the party instituting the competition, for the purpose of consultation with regard to the preparation of the programme of competition, and to nominate the professional advisor or advisors.

It shall be the duty of the professional advisor or advisors to examine all drawings submitted by the competitors, and to place out of competition any competitor who has not submitted his designs at the date fixed for their reception, or who presents details or models which are not called for, or whose drawings do not conform exactly in number and character with the requirements of the programme, and that if placed out of competition his plans shall receive no further consideration by the party instituting the competition.

In as much as the object of a competition is to adopt the general motif of a design to be further elaborated, and to select an architect for the work rather than to secure plans perfectly studied in all of their details, the undersigned will enter upon no competition unless it shall be agreed that an award shall be made and that an architect shall be appointed on the consideration of the relative merits of the several schemes as shown by the drawings submitted, and that no demand shall be made for additional drawings or for a new competition.

The undersigned are of the opinion that all designs should be signed by their authors, and also that it is desirable that each competitor who has qualified by having his designs accepted by the professional advisor or advisors as complying with the terms of the competition, shall have an opportunity to personally explain his design to the party instituting the competition, in the presence of the professional advisor or advisors.

This has been signed by the following, up to date:

Geo. B. Post	McKim, Mead & White
Bruce Price	Henry Rutgers Marshall
R. H. Robertson	H. J. Hardenbergh
R. W. Gibson	Babb, Cook & Willard
Edw. H. Kendall	Geo. Keister
Rossiter & Wright	Carrere & Hastings
Berg & Clark	Renwick, Aspinwall & Owen
Jas. Brown Lord	Charles C. Haight
R. H. Hunt	Clinton & Russell

NOTES AND COMMENTS

THE Land Title Trust Company of Philadelphia, invited competitive plans for a new office building, and when it had in twenty designs, submitted them to a pet architect of Chicago and gave him the work without a competition. This is the kind of honor that supports the trust companies, and goes to show how genius is rewarded.—*Appeal to Reason*.

THE STOCKHOLM ordinance regulating the height of a building according to the width of the street could be adopted with profit in New York and Chicago. In the Eastern metropolis certain down town streets, like Nassau

street, are converted in the lofty buildings into mere canyons into which the sunlight never reaches and through which winds sweep with terrific force. For sanitary reasons alone these high buildings that form a solid wall on each side of narrow streets should be prohibited.

Our old friend, The Californi Architect and Building News, still keeps in front ranks of the profession, and continues to do yoeman service for its clients and patrons. It is now in its eighteenth volume and is about as vigorous as when it was in its swaddling clothes under the Wolfe regime. We congratulate our cotem on the clean, healthy appearance of the last issue.—*The National Builder.*

A new patent toy.—B. E. Henriksen, San Francisco, Cal., No. 581,420. Dated April 27, 1897. The object of this invention is to provide a simple and attractive toy adapted to produce a sound which may be more or less an imitation of the natural voice of the creature in the likeness of which the toy is constructed. It comprises a hollow resonant figure having a vibratable member, a head with a flexible or hinged neck, a lever within the figure hinged at its lower end and extending upwardly into the neck having its free end adapted to bear against the same to throw the head up, a cord attached to the lever at a point above its hinge and passing outwardly through the vibratable member whereby it may be operated to cause the figure to give forth a sound.

THE GATEWAY AND WATCH TOWER AT POINT TIBURON.

A freight elevator used in hoisting men and building materials at the new building for the New York Life Insurance Co., dropped seven stories. There were six men on the car, but none were injured, as they clung to the beam across the top of the cage and were only hurt by the shock causing them to let go when the cage struck the cellar floor.

It is said that receipts of tin plate by rail into San Francisco were scarcely half as heavy in 1896 as in 1895. During the first three months of this year, however, there has been an important movement in that direction, and it is probable that the figure for the first quarter of this year will be as great as for the whole of last year.

BOOKS AND PERIODICALS.

STONES FOR BUILDING AND DECORATION, by George P. Merrill, Curator of Geology in the United States National Museum, second addition, revised and enlarged, 8 volumn cloth $5 00. 516 pages and 19 full page plates and 18 figures in text. Published by John Wiley & Sons, New York—London, Chapman & Hall, Limited, 1897.

This handsome volume fully illustrated does credit to the publishers, and is made more valuable by a very complete index that always adds so much to the value of a book.

The preface of the second edition informs us that the work of revising and bringing down to date the present edition, as many additions and alterations have been made here an there throughout the text as was prossible without incurring the expense of entirely resetting. Over fifty pages of reading matter and full-page plates have thus been added, and while the revision is not as complete as the author would have been pleased to make it, is believed that the usefulness of the volume has been very materially increased. As before, the writer is indebted to the authorities of the National Museum for permission to use electrotypes of plates that have appeared in the publications of that Institution.

HOT WATER MANUAL with information and suggestions on the best methods of heating public, private and horticultural buildings. Treating on the high and low pressure systems, bath apparatus, hot water supply for public institutions, duplicate boilers, radiators, laundry drying stoves, swimming baths, Turkish baths, causes of and hints to prevent failure—by Walter Jones, Chicago. The American Artisan Press, 1897.

This little volume of about 200 pages should be in the library of every architect as the illustrations make clear many points that might be over looked when making plans for the heating of buildings either public or private. The title as given above fully explains the character of the book.

THE CALIFORNIA STATE MINING BUREAU have issued Bulletin No. II, under the direction of J. J. Crawford State Mineralogist on the oil and gas yielding formations of Los Angeles, Ventura and Santa Barbara Counties. Part 1 by W. L. Watts, M. E., Field Assistant. This Bulletin contains much information of value to the public, and must be very interesting to those engaged in the oil business either as producers or consumers of this article. The illustrations are good and reminds one of the early days in Philadelphia, when oil was searched for upon Oil Creek.

DOGS IN CUTLERY WORK.

A VERY curious use for dogs is noted by E. Edmond Renoir, in an account he lately gave on the subject. He says that dogs are largely employed in the cutlery works of Thiers of France. Each grinder, man or woman, takes in winter a dog to the grinding room, and the four-footed beast stretches himself out upon the back of his master or mistress for no other earthly purpose than to keep them warm. Instead of occupying an upright or sitting position at their work, the grinders, both male and female, have to lie flat upon their stomachs on planks placed horizontally on a scaffolding, which rises above the grindstones. Sheepskins are thrown over the planks to relieve the hardness of the wood, and the head and shoulders of the operators project over the ends of the planks, while their arms reach down vertically to the rim of the grindstone. These latter are kept in continual motion by the belting, driven by water power. The grinder, extending his length on the plank, becomes very soon fatigued and enfeebled, and cold would have a very injurious effect upon him, whilst he would have no power to resist it. As soon as a chill strikes him he whistles for his dog, which immediately springs upon the bench, and lays himself upon the extended legs of his master, covering him as much as possible and supplying him with a much needed warmth. Verily these canine friends have great claims on our gratitude!—*The World's Progress.*

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street.

Seth Babson, Pres. W. P. Moore, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. F. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

Oscar Lewis, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. M. V. Brady, Sec.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

CERTIFICATE OF ARCHITECT.—Under a contract providing that the work should be done under "the immediate supervision" of the architect and that payments should be made on certificates of the architect, the owner is not bound by certificates issued, in the absence of the architect, by one to whom he had attempted to delegate his authority.

Monahan v. Fitzgerald, Sup. Ct. Ill., 45 Northeastern Rep. 1013.

NO LIEN FOR DEFECTIVE WORK AND MATERIALS.—Contractors for putting on lath and plaster, under a contract providing that the mortar should be so applied that the key would be solidly filled, and that the work should be in perfect order when finished, cannot claim a lien, where, by reason of using laths wider than those specified in the contract, and placing them near together, and failing to press the mortar so as to form the proper key, so that a great part of the plaster fell soon after it had dried, though no objection was made by the architect as the work progressed.

Monahan v. Fitzgerald, Sup. Ct. Ill., 45 Northeastern Rep. 1013.

LIABILITY FOR STREET OBSTRUCTIONS.—Where the owner of a building directs the independent contractor having the contract to tear down a building to place the material in the street, the city having given the owner permission to place material in the street, provided the gutter was not obstructed, the owner is liable for damages caused by the contractor placing material so as to obstruct the gutter.

Bohrer v. Dienhart Harness Co., App. Ct. Ind., 45 Northeastern Rep. 668.

LIEN AFTER TAKING NOTES.—Upon the completion of a structure, three notes were taken by the contractors from the owner for the balance due, which notes were indorsed and sold to a bank; and within four months after the completion of the structure, and while the bank was the owner and holder of the notes, the contractors made and filed an affidavit in due form for perfecting a mechanics' lien to secure the indebtedness evidenced by the notes. The Supreme Court of Ohio held that such lien was valid.

Standard Oil Co. v. Sowden, 45 Northeastern Rep. 320.

RIGHT OF PARTIES IN DIVISION WALL.—A party wall, built by one of two adjoining owners, and resting partly on the ground of each, must be one that both of them can use, and have the right to use; and the owner of a lot who sells part of it, restricting by condition in the deed, the height of the building to be erected thereon, cannot extend a party wall built between the two parts above such height for his own exclusive use, but if extended it must be built without openings, and the owner of the other part will have the right to use it, on proper payment, by adding to the height of his building.

Fidelity Lodge v. Bond, Supreme Ct. Ind. 45 Northeastern Rep. 338.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

LAW LIMITING THE HEIGHT OF DWELLING HOUSES IN THE CITY OF NEW YORK.

CHAPTER 321, Laws of 1887.—An Act to regulate the height of fireproof houses in the city of New York.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:

SECTION 1. The height of all fireproof dwelling houses and of all fireproof houses containing one or more power passenger elevators used or intended to be used as dwellings for more than one family, now or hereafter constructed or completed, shall be regulated in proportion to the width of the widest street and avenue upon which they abut, and such height measured from the sidewalk line and taken in cases through the centre of the facade of the house to be erected, including rttics, cornices and mansards, shall not exceed one hundred and fifty feet upon all streets and avenues exceeding seventy-nine feet in width, and one hundred feet upon all streets and avenues not exceeding seventy-nine feet in width.

§ 2. All buildings mentioned in the first section of this act, provided the same have a frontage exceeding forty-five feet and exceed one hundred and thirty seven feet in height, shall have two separate firepoof stairways leading from the ground floor to roof, one of which shall be remote from elevator shafts.

§ 3. All statutes in force at the time of the passage of this act, except as herein modified, relating to buildings in the city of New York, shall apply to the buildings hereinbefore referred to.

§ 4. All acts or parts of acts inconsistent with the provisions of this act are hereby repealed.

§ 5. This act shall take effect immediately.

BUSINESS MOSAICS.

In calling attention to L. E. Clauson & Co's. advertisement upon the outside cover of this journal we would say the combination in Clawson's patent was a happy idea and as it complies with the new fire ordinance leaves nothing more to be desired in the way of being safe.

Maud—What is the height of your ambition, dear? MARIE—(blushing)—Oh, something between five and a half and six feet.—*Tit-Bits.*

The Ives Patent Sash Locks are now ready, in cold rolled steel, bronze and brass in all the popular finishes.

The acknowledged superiority and complete manner in which they perform the work intended make their sash lock a favorite among architects and builders. A new catalogue of window hardware specialties can be obtained by addressing Hobart B. Ives & Co., New Haven, Conn.

Bacon—What are you doing with a picture of a football pinned to your coat? EGBERT—Oh, yes! My wife pinned that there so as to remind me to have my hair cut.—*Yonkers Statesman.*

Considerable interest has been expressed in building circles in an exhibition of several pieces of old roofing tin now in the possession of N. & G. Taylor Company of this city, and which are highly esteemed by the members of this concern as practical illustrations of the efficiency of the "Taylor Old Style" brand of extra heavy coated roofing plates, under the severest tests of both time and wear.

One of these relics came from the roof of the old Bloodgood's hotel on Dock street, this city. The old house was demolished some years ago to make room for the Pennsylvania R. R. Co.'s Freight Station. When the roof was taken off, notwithstanding the fact that it had been in active wear for forty-four years, the tin was found to be bright and perfect, and, in fact just as good as when first put on.

The second and, perhaps, no less important feature of the exhibition is a piece taken from the roof of a residence at Edgewater Park, N. J. This was put on in 1855, and was in active wear for thirty-five years and never painted but once. The piece on exhibition certainly indicates that it is even now equal in every respect to the best plates, bright and new as they are now in stock and for sale on the floor of the company's warerooms.

The third piece on exhibition was taken from the roof of a building at Independence, Mo. This piece was sent by the owners of the building with a letter of explanation stating that the roof had been in active service for over thirty years and had never been painted.

Messrs. N. & G. Taylor Company's works are located on Tasker street, between Swanson and Meadow, and the public is invited to see how good roofing tin is made.

From *The Philadelphia Real Estate Record and Builders Guide*, December 25, 1895.

Mr. M. S. James, Flood Building, room 27, who is the Pacific Coast representative of the J. L. Mott Iron Works, has in his show rooms a collection of almost every thing in the plumbing line to satisfy the most exacting, you can convince yourself of this fact, by calling upon Mr. James and giving a careful examination of the various contrivances he has on hand to make the house not only healthy but beautiful at the same time; if you have not time to call, examine his advertisement in the journal on page v.

Watts—I saw you down town this morning with your better half. N. PECK—If you please, she is not my better half. She is the whole thing.—*Indianapolis Journal.*

The John Douglas Co., 208 Ellis street, San Francisco, are manufacturers of an absolutely noiseless tank, with superior quality of seats and crockery. Any combination of water closet that you desire can be furnished at short notice. See their advertisement on page viii of this journal.

"His life is an open book." "Yes; he never closed accounts.—*Chicago Journal.*

The finger of science points to Graphite paint as the paint of the future for the protection of all exposed iron and metal work. Prof. Spennrath, Director of the Technical School of Aix-la-Chapelle, lately won the $2,000 prize offered by the Society for the advancement of the Industrial Arts for the best essay on Protective Paints. The prize was not won simply by theoretical demonstrations, although the professor furnished scientific reasons also, but by most carefully conducted practical experiments with various pigments and oils, covering several years' time. The results demonstrated that a properly made paint of graphite and boiled linseed oil is the most suitable for protecting structural iron work, roofs, etc., exposed to the destructive agencies of heat, cold, storms, etc.

Running parallel with these results are the facts demonstrated by those who have used Dixon's Silica Graphite Paint during the past 30 years. Roofs and iron work properly painted with Dixon's paint have not required repainting in 15 to 20 years. As the season for painting is now close at hand it may pay those interested to write to the Joseph Dixon Crucible Co., Jersey City, N. J., for circulars.

Tommy—Oh, paw! MR. FLAGG—Well? TOMMY—How can a solid fact leak out?—*Indianapolis Journal.*

Mr. Charles J. Waterhouse, 35 New Montgomery street, is agent for the sale of Cabots' Creosote Shingle Stain, this well known stain manufactured by Samuel Cabot, Boston, Mass., will not crack or peel as paint does, being in the wood, and not wholly on the surface.

Mr. Waterhouse is also agent for N. & G. Taylor Co., Philadelphia, Pa., the well known manufacturers of tin plate for roofing, as well as the Pancoast Ventilator.

CITY BUILDING NEWS.

Alvarado and Hoffman. Cottage; owner, J. Heyman; cost $1600.

Baker Alley off Pine. Removal of old structure and erection of a row of one-story brick buildings; owner, Mr. Neychell; superintendent, J. Miron; day's work; cost $20,000.

Baker and McAllister. Two two-story frames; owner, Emma Joseph; architect, W. H. Lillie; contractors, Moore & Cameron; signed, April 14; filed, April 22; cost $3850.

Baker and Pine. Three-story frame; owner, A. Clarke; architect, C. M. Rousseau; contractor, S. F. Hodgkins; signed, April 27; filed, April 29; cost $6255.

California near Lyon. To build; owner, P. J. Fitzpatrick; architect, T. J. Welsh; contractor, Frank Gallagher; signed, April 28; filed, April 30; cost $3875.

California near 1st Ave. Cottage; owner Peter Swensen; architect, W. H. Armitage; contractors, Hannah Bros.; signed, April 23; filed, April 27; cost $1500.

Castro near 20th. Four two-story frames; owner, F. Nelson; cost $18,000.

Chattanooga near 22d. To build; owner, R. W. Collins; architect, E. J. Vogel; contractor, Geo. McLeod; signed, April 20; filed, April 23; cost $1,500.

Chattanooga near 24th. Additions and alterations; owner, John Craig; architects, Rowell & Collins; contractors, Doyle & Son; signed, April 24; filed, April 28; cost $2040.

Elgin Park Ave. Additions and alterations; owner, C. Oliva; architect, C. A. Meussdorffer; contractor, P. A. Antonelli; signed, April 20; filed, April 21; cost $1600.

Eighteenth near Harrison. All work for new flat and alterations; owner, Mary Hanley; contractor, L. Cimco; signed, April 17; filed, April 19; cost $1140.

Fell near Central Ave. Two-story frame; owners, Edward and Sophia Wharton; architect, D. V. Deuel; contractors, Petterson & Person; signed, April 16; filed, April 17; cost $2000.

Filbert near Mason. Alterations and additions; owner, Morris Windt; architect, R. H. White; contractor, John Furness; signed, April 27; filed, May 3; cost $1880.

Fillmore near Fell. Brick church; owner, P. W. Riordan; architect, T. J. Welsh; contractor, P. Fitzsimon; signed, April 21; filed, April 23; cost $34,636 Carpentry, glazing, etc.; contractor, D. Powers; cost $8230. Slating, tinning, etc., sub-contractor, Conlin & Roberts; cost $2200. Iron work; sub-contractor, Clark & Sons; cost $6500. Grading and concrete work; contractor, P. Fitzsimon; cost $4569. Plumbing; contractor, James E. Britt; cost $768.

Folsom near 21st. Three-story frame; owner, T. McEnearny; contractor, W. Hebbing; signed, April 14; filed, April 15; cost $3880.

Folsom near 21st. Frame dwelling and stable; owner, Julia O'Kane; architects, Townsend & Wyneken; contractor, W. M. Constable; signed, April 10; filed, April 21; cost $1750.

Fulton near Lyon. To build; owners, A. J. and S. T. Scandrett; contractor, Wm. Plant; signed, April 17; filed, April 17; cost $3470.

Folsom near 24th. To build; owner, D. Von der Mehden; architects, Martens & Coffey; contractors, Reil & Ahlgren; signed, May 4; filed, May 5; cost $3800.

Geary and Stockton. Ornamental cast iron work; owner, Spring Valley Water Works; architects, Clinton Day; contractor, Josh Hendy Machine Works; signed, March 29; filed, April 15; cost $6675. Plastering first and second stories; contractor, C. Dunlop; cost $6000. Plastering third and sixth stories; contractor, C. Dunlop; cost $4785. Iron work and elevator, etc.; contractor, Winslow Bros.; cost $17,000. Vault linings; contractor, C. B. Purcells; cost $5370. Steam heating, etc.; contractor, G. H. Tay; cost $6600. Glass and glazing; contractor, W. P. Fuller & Co.; cost $11,000.

Green near Dupont. Alterations and additions; owners, M. Compagni & Belianti; contractor, J. Schiavo; signed, April 15; filed, April 17; cost $1300.

Haight near Scott. To build; owner, John Reutiler; architects, Martens & Coffey; contractor, J. Bucher; signed, April 20; filed, April 22; cost $2795.

Jackson near Stockton. Brick and stone work for three-story frame; owner, M. Schnappert; architect, A. C. Lutgens; contractors, Miller & Beck; signed, April 26; filed, April 29; cost $3600. Carpenter work; contractor, Frank Stemmann; signed, April 26; filed, April 27; cost $2500.

Jessie near 13th. Two-story frame; owner, Catherine Reingpach; architect, C. I. Havens; contractor, A. Cimco; signed, April 15; filed, April 15; cost $2150.

Kearny and Sutter. Brick work for additional stories; owner, Adams Company; architect, H. A. Schultz; contractor, H. H. Larsen; signed, April 24; filed, April 25; cost $4086.

Kearny and Sutter. Cast iron work, steel beams, etc.; owner, Adams Co.; architect, H. A. Schultz; contractor, H. Ralston; signed, April 28; filed, April 29; cost $7000.

Larkin near Green. Carpentry, brick work, etc.; owner, H. G. Otis; architect, C. A. Henderburg; contractor, O. J. Blanckfield; signed, April 30; filed, May 1; cost $3897.

Lyon near Golden Gate Ave. To build; owner, L. Friedlander; contractor, W. H. & T. Kinread; signed, April 15; filed, April 16; cost $3000.

Lyon near Grove. To build; owner, T. J. Dugan; architect, T. J. Welsh; contractors, Hansbrough Bros.; signed, May 1; filed, May 4; cost $3497.

McAllister near Pierce. Alteration and additions; owner, Jos. Figel; architect, R. H. White; contractors, Campbell & Pettus; signed, April 12; filed, April 16; cost $5500.

Mission near 23d. Plastering work; owner, Mission Lodge Masonic Assn.; architects, Herman & Swain; contractor, C. C. Morehouse; signed, April 12; filed, April 20; cost $1666. Painting, etc.; contractor, H. Maundrell; signed, March 19; filed, April 20; cost $670.

Montgomery near California. Additions and alterations; owner, Selby Smelting and Lead Co.; architects, McDougall & Son; contractor, J. H. McKay; signed, April 21; filed, April 22; cost $1445.

Napa near Michigan. Carpentry for skylights; owner, Union Iron Works; architects, Percy & Hamilton; contractor, Jos. F. Forderer; signed; April 24; filed, April 24; cost $4495.

Oak near Ashbury. To build; owner, Emily Eliaser; architect, I. Eliaser; contractor, J. B. Glunz; signed, May 3; filed, May 4; cost $3275.

Page near Scott. To build; owner, Frank Koch; architects, Salfield & Kohlberg contractor, C. Kreecker; signed, April 27; filed, April 28; cost $2800.

Pierce and Filbert. To build; owners, H. E. & L. E. Hartmann; contractor, Jas. Pattinson; signed, March 25; filed, April 24; cost $2102.

Powell near Clay. Three-story frame; owner, Daniel F. Numan; contractor, C. W. Duffy; signed, April 12; filed, April 16; cost $3700.

Sacramento and Gough. Alterations and additions; owner, Emma Joseph; architect, W. H. Lillie; contractors, Moore & Cameron; signed, April 14; filed, April 20; cost $3125.

Sacramento near Walnut. Two-story frame; owner, John M. Lippincott; contractor, T. C. Cochrane; signed, April 20; filed, April 21; cost $2850.

Sacramento near Cherry. Brick work for two-story frame; owner, Frank H. Foote; architect, J. H. Littlefield; contractor, C. E. Nichols; signed, March 14; filed, April 17; cost $2850.

Sanchez and 18th. To build; owner, Brun Cordes; architect, A. J. Harnett; contractors, Petterson & Person; signed, May 1; filed, May 4; cost $2610.

Scott and Vallejo. To build; owner, Julia Sontag; architects, Corbead & Corbead; contractor, C. M. Depew; signed, April 14; filed, April 15; cost $5665.

Seventh Ave. near Clement. Cottage; owner, W. M. Lacey; architect, T. P. Ross; contractor, T. H. Soule; signed, April 23; filed, April 24; cost $1400.

Seventh and Natoma. Raising and addition; owner, Louis Altmark; architect M. J. Lyon; contractors, Elder & McLaughlin; signed, April 30; filed, May 3 cost $1025.

Seventeenth and Collinwood. Two two-story frames; owner, Mrs. Mary Shephard; architect, W. H. Lillie; contractors, Peterson & Person; signed, April 27; filed, April 28; cost $4613.

Spruce near Washington. To build; owner, S. Dolliver; architect, T. J. Welsh; contractor, W. Plant; signed, April 21; filed, April 26; cost $3347.

Sutter near Van Ness. Alterations; owner, Dr. W. F. McNutt; architect, Clinton Day; contractors, Geo. Davis & Son; signed, April 24; filed, May 3; cost $3650.

Sutter street No. 120. Electric elevator; owner, A. W. Ross; architects, Percy & Hamilton; contractors, Cahill & Hall Elevator Co; signed, April 26; filed, April 27; cost $2540.

Tenth near Harrison. To build; owner, P. Barry; architect, D. C. Coleman; contractors, McDonald & Foley; signed, April 28; filed April 29; cost $2550.

Thirteenth and Stevenson. To build; owner, W. H. Blamey; architect, A. C. Meussdorffer; contractors, Wilhelm & Taylor; signed, April 22; filed, April 22; cost $2733.

Turk and Taylor. Alterations and additions; owner, A. W. Wilson; architects, Shea & Shea; contractor, J. H. McKay; signed, April 14; filed, April 16; cost $4620. Brick work, etc.; contractor, Peacock & Butcher; cost $8300. Plumbing, etc.; contractors, Allen & Looney; cost $5600.

Twenty-second near Treat Ave. One-story frame; owner, Miss Bridget Cox; architect, M. J. Welsh; contractor, Jas. A. McDonald; signed, April 14; filed, April 14; cost $1600.

Twenty-second and Treat Ave. To build; owner, Charlott Hahn; architect, H. Geilfuss; contractor, W. Harstmyer & Co.; signed, April 17; filed, April 19; cost $2550.

Twenty-third near Hoffman. Three one-story cottages; owner, J. Heyman cost $4500.

Union near Laguna. To build; owner, H. K. Devely; architects, Mooser & Son; contractor, A. Guilbert; signed, April 15; filed, April 16; cost $2948.

Union near Fillmore. Two-story frame; owner, Amelia V. R. Pixley; contractor, John Wiren; superintendent, W. C. Pease; signed, April 19; filed, April 22; cost $7994.

Van Ness and Clay. Windows, doors, etc., owner, Claus Spreckels; architects, Reid Bros; contractor, Neilsens Bros Co; cost $5505.

Washington and Locus. Foundation, etc.; owner, J. T. Polheim; architect, A. W. Marquis; contractors, Gray Bros; cost $2982. Carpenter work; contractor, G. H. Moore; cost $7500. Plumbing, etc; contractors, Berhman Bros; cost $1240.

Washington near Taylor. Alterations and additions; owner, Henrietta Lucus; contractor, C. Douglass; signed, April 22; filed April 24; cost $1464.

OLIVER EVERETT Secretary.

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

SINCE our last number some of the San Francisco Supervisors have shown a very lawless spirit, unworthy of their position, in attempting to break the law regarding projections onto the sidewalk, and we are glad that Mayor Phelan stands up against any such anarchism.

As long as we have a law let us keep to it and admit no special privileges; if it is a bad law let it be abolished. We have altogether too much of this kind of word. To take another example, the laying of sidewalks—this work is ordered done, those property owners who are law abiding do the work in front of there property, while others refuse and we see part of the sidewalk of a block paved while other parts are left undone for years. This should not be allowed but all should be treated alike. While we are on this subject we will draw attention to the obstruction of the main street of the city by a mass of rock extending nearly half way across the street, this has been in this state for many years.

IT IS almost impossible now-a-days to take up a trade paper, or a periodical of any description, without finding more or less space devoted to the economic aspect of the existing conditions of civilized society. Times have been going from bad to worse with disheartening monotony for many years, and the number of idle unemployed discouraged and desperate men and women has been as steadily increasing. It is the exception rather than the rule when the daily papers of San Francisco appear without recording the suicide of some poor despondent human being, driven to seek death from lack of the opportunity to earn his daily bread. Nor is the condition of the average business man much better than the lot of the mechanic and laborer. Here is an editorial jotting from *Painting and Decorating*:

"Much of the cut-throat competition that afflicts the painting trade to-day is brought about by indiscriminate granting of credits by manufacturers and dealers, who take almost certain risk of loss rather than lose a sale," and the

editor goes on to favorably quote another writer who says: "I would decline to compromise any account for less than two-thirds of its value. It is not fair to the competent and honorable merchant that his competitor, who may have been neither, should be provided with goods at half cost to pursue again the methods which brought him to grief and very likely at the same time injure those who pay one hundred cents on the dollar for their goods."

The following is a clipping from *Stone*:

"Boston, Mass.—A bill has been introduced into the legislature to prevent the bring into this State of any stone cut outside of it, and the debate on it brought out the fact that the master builders and union stone-cutters of this city are agitating strongly against the bringing in of stone cut by convicts, which, they assert, is being done to not a small extent, to the detriment of business. An amendment was therefor tacked to the bill to prevent the bringing in of stone cut by convicts, but this, it was asserted, was more important than the scope of the original bill, and it was thrown out. It is stated by the stone-cutters that there is no doubt but that stone is being brought into this city which has been cut in the prison yards of the West, and the case which is cited is that of the stone used on the Brazer building, which, it is asserted, is out of the yards of the prison at Joliet, Ill. It is said that this stone comes certainly from farther West than Rotterdam Junction, to which point it has been traced, and the presumption is that it comes from some where near Chicago. At the building the foreman says that the stone is Bedford, but that he does not know where it is cut. It is said that E. R. Brainerd, of Chicago, who has the stone-cutting contract, has a good deal of his work done at Joliet, and also that a good deal of cut stone has been shipped from that institution lately, although it cannot be traced direct from there to the building."

Here is what a writer in *Lumber* says: "In perhaps no other business in the world is it necessary to use so much tact and keen diplomacy as in the lumber business. Many men fail from just a lack of this propensity. They are just square, honest, easy-going men, thinking that because they are square and right everybody else is. In these days of close competition, however, a man who has not cut his eye teeth is *not in it*."

In other words in the business world of to-day the honest man cannot succeed, but must give way to the man who is shrewd enough to use "keen diplomacy" in place of fair dealing.

And we could go on and on, quoting from one journal after another, showing how the honorable business methods of former timee have been supplanted by trickery and double-dealing, until the ordinary human being is apt to become a confirmed pessimist knowing as he must, that the fierce competition in every line of business tends to lower the scale of wages that the working-man receives thus lowering the standard of living, and making still more bitter the struggle between capital and labor.

CONCERNING SAN FRANCISCO'S NEW POSTOFFICE.

FROM A Washington dispatch to the *Call* dated June 2, we learn that Mr. Aiken, the present Supervising Architect of the Treasury Departmtnt, will be superseded on July 1, and he has practically been relieved of the duties already.

Mr. Kemper, the chief executive officer, is acting as architect and will continue to do so until Mr. Aiken's successor is appointed. Mr. Aiken is still in the office, however, and said to the *Call* correspondent to-day:

"Of course we cannot tell what stone will be used until the bids are opened. If I had my way about it California material would certainly be used, but still if the Eastern quarries should underbid the California people the contract would go there, provided they were responsible bidders.

"My idea has been all along to use granite for the lower part of the building—that is to say, that part of the building up to the first or, maybe, up to the third story—and construct the upper part of marble.

"In this case the marble would not be rough hewn, but cut smooth, like the granite of the Treasury building here. The California granite is excellent, if accessible. I do not think that Eastern firms could transport granite to California and underbid the Raymond quarries.

"As for the marble, I will say that I think the Inyo stone of excellent quality. Of course it may be said that it is somewhat inaccessible on account of the lack of railroad facilities in that part of the country, but at the same time I believe that it could be laid in San Francisco as cheaply or more so than the Eastern marble. But, of course, these are problems for the quarrymen to solve themselves.

"The department cannot act intelligently until the bids are opened. It may be that the Inyo quarrymen would have to expend a considerable amount of money to put in a plant, but they would doubtless be quite willing to do that if they should get this contract."

Chief Executive Officer Kemper said that it was his opinion that granite would be used in the construction of the building. He explained that formerly it was the practice of the department to advertise for bids without specifying to whether the building was to be constructed of granite, marble, sands tone or lime stone, this matter not being decided until it was seen which would be the cheapest when the bids were opened; but latterly it has been the policy to decide what character of stone would be used and then advertise for bids. This will be done in the case of the San Francisco building.

The chances are altogether, therefore, that one of the Raymond quarries will get the contract and if a part of the building should be constructed of marble, the Inyo County people will doubtless be able to underbid the New England people.

The kind of stone to be used will not be settled, however, until the new supervising architect takes charge of his office.

MARIA KIP ORPHANAGE.

WE HAD the pleasure of attending the opening of this splendid institution on the twenty-second of May, since which time over one hundred children have been comfortable settled in their new home.

The building appears to contain every thing in the way of health and comfort that can be desired for the welfare of the children. In a late number of this journal we published the perspective and plans of the building, which do so much credit to the architects Percy & Hamilton.

No one can look at these children, but will be convinced that good care and attention is given to their welfare—a more happy, healthy, neatly dressed lot of children can not be seen anywhere.

HOUSING OF PEOPLE OF SMALL INCOMES.

No. 8.

INTERVENTION OF PUBLIC BODIES.

[CONTINUED FROM LAST NUMBER]

IN MATTERS of private concern the amount of public interference has always been a subject of dispute, and it is evident that no law can be laid down governing the subject; for conditions are constantly changing, making it impossible to draw any hard and fast line at which one can command. "Thus far shalt thou go and no farther."

The amount of what is often called paternal government varies in different nationalities as well as at different times.

The matter of providing homes for those of small incomes is the part of paternal interference which we are interested in now.

Taking the smallest country first we find in Belgium a semi-official bank called *la Caisse Generale d' Epargne et de Retraite* which loans part of its reserves at reduced rates to members of two other institutions, the Loan Companies at 2½ per cent and the Building Societies at 3 per cent; the general principle laid down being loaning only through an intermediary.

In certain localities, agricultural districts, for example, and other places where no intermediary companies of this sort exist, a workingman, through a solvent neighbor who will go security for him, may get money from the General Savings Bank at 3 per cent.

The first step which a workingman takes when he starts to acquire a house is to address himself to the local committee of patronage. He secures from it a certificate establishing the fact that he is a bona fide workingman. This certificate is attached to the act of sale or to the mortgage passed between himself and the company. It is this certificate which gives him the benefit of a reduction of charges for registration fees, etc., which are mentioned in the text of the law.

In order that the bona fide workingman alone may benefit by the advantages accorded, the directors of the savings bank have fixed upon 5,500 francs ($1,061.50) as the maximum cost, land included, of a workingman's dwelling.

Reduction of taxation is made upon incomes of companies or public administrative bodies engaged in transactions having reference to the purchase, building, sale, or rental of workingmen's houses. These reductions are very considerable, and are designed by the government especially to favor the work of companies of this sort.

We may remark, in passing, that this is strictly class legislation and as such is now generally considered objectionable on the score of perpetuating class lines. That is where the too much paternity comes in; any legislation for the public good should be for the benefit of everybody and not restricted to the working classes or any other class. We will continue, and drop out of the subject the further consideration of this part, which is entirely out of line with the genius of America.

To protect the General Savings Banks it is authorized to insure the life of the borrower in order to guarantee reimbursement of the loan in case of death of the party insured at any time during the period. Money is advanced for the construction or purchase of a home and a policy of insurance on the life of the debtor is taken out by the creditor.

The annual payment for $1000 payable in ten years is $123.30, while in the California Building Societies the annual payment for the same amount is $160.20—the latter charge 7 per cent while the Belgian charge 4 per cent.

Should all the intermediary profits be done away with it could easily be 2½ per cent. So one can imagine the tremendous impulse that would be given to the obtaining of homes by the people should the Government lend money directly to them at say 2½ per cent.

Besides the advantage of a low rate of interest a national savings bank offers edvantages over any local institution. Its operations extend throughout the whole country, and local branches exist everywhere. The conditions upon which the loans are given are uniform throughout the land. On the other hand there are certain distinct business advantages claimed for the practice of loaning through an intermediary. Account keeping and receiving and recording weekly or monthly payments would be an enormous task for a national or state institution to undertake. Under the Belgian system the intermediary companies attend to all such work. Moreover, local organizations can watch over the construction and see that the houses built are such as befit the neighborhood. Another advantage claimed for the employment of an intermediary is this: When debtors fail to meet their obligations, local companies acting in accordance with their principle of social helpfulness, can much better take into consideration the circumstances bringing about default and can judge whether leniency should or should not be extended.

Those in a position to know say that formerly the idea of building workingmen's houses directly by the government was exceedingly popular among the laboring element of Belgium. Recently they have begun to take a much greater interest in companies created under the law, and to avail themselves of the benefits offered. The increase in the number of deposits, all guaranteed by the government, has gone steadily on, showing that there has been no lack of confidence in the bank since housing operations were begun. The total increase in deposits during the four years from 1886 to 1889, inclusive, was 93,527,010 francs ($18,050,712.93); during the next four years, viz., 1890 to 1893, inclusive, it was 107,593,676 francs ($20,765,579.47).

Let us take up the advantages claimed for the Intermediary System. The account keeping being any more of a task under one control than under a number of local concerns, must fall of its own weight. It seems to us that one large establishment must have less trouble in that respect than several small ones.

In regard to local organizations watching over construction and seeing that houses are built befitting the locality the Government Bank would certainly have branches in all cities and districts composed of local men who would be just as well able to look after local affairs as private companies. The last advantage mentioned is a questionable advantage.

The increase of the amount of deposits in the semi-official General Savings Bank of Belgium, as shown by the above statistics chiefly goes to show the natural confidence of the people in any concern connected with the Government even though they simply guarantee the depositors against loss; they have still more confidence when dealing with a bank which is entirely in the Government control as is witnessed

by the popularity of the Postal Savieg's Bank of the United Kingdom.

In France much the same system exists as in Belgium as to encourageing the building of workingmen's homes, and the same law as to insuring the life of the borrower to secure payments of his installments should he die.

In Austria nothing much has been done in this matter except special remission of taxation in favor of this class of dwellings.

State intervention in the housing of labor in England goes back more than forty years. Under the influence of Lord Shaftesbury, a philanthropist, the enactment of 1851, which was especially designed to meet the needs of working people, was passed. The act has remained a dead letter, never having been utilized. Since that time a series of measures has been placed on the English statute books, so that to-day corporations are authorizd, indeed compelled, to provide accommodation where expropriations have taken place for at least one-half of the persons dispossessed. An attempt, however, is always made to dispose of property to private individuals, under special restrictions as to the character of construction and the rents to be charged. Builders are not anxious to acquire this class of property, and so it naturally happens that corporations are compelled to build and become landlords.

The principal statutes authorizing public authorities to directly interest themselves in the housing of the masses are as follows:

The laboring classes lodging houses act, 1851.—This act permitted certain populous local divisions in England to raise money by mortgage on the rates for the purpose of providing lodging houses for the working classes, the houses to be regulated by commissioners appointed under the act. Tenement lodging houses, not common lodging houses, were referred to in this act.

2. *The laboring classes dwelling houses act, 1866.*—This statute authorizes the public works loan commissioners to make advances for the purpose of assisting in the purchase of land and buildings, or in the erection, alteration, and adaptation of buildings to be used as dwellings for the laboring classes. The effect of this act is to authorize the council to erect dwellings for the laboring classes. Under this enactment, for example, the city of Liverpool erected the Saint Martin's cottages.

3. *The artisans' and laborers' dwellings improvement act, 1875.*—This act applies to the city of London, the metropolis exclusive of the city of London, and urban districts of 25,000 population or over. It provides for clearing "unhealthy areas" and the rearrangement and reconstruction of streets and houses within such areas. The scheme must have the approval of the local government board, and must provide for as many persons of the working classes as may be displaced. It was under this act that the Victoria Square artisans' and laborers' dwellings and the Juvenal laborers' dwellings were built.

4. *The municipal corporations act, 1882.*—Under this law corporations are authorized, with the approval of the treasury, to make grants or leases for terms not exceeding nine hundred and ninety-nine years of any land belonging to them for the erection of workingmen's dwellings. The corporation is allowed to improve this land by making roads, drains, walls and fences at such an expense as the treasury may approve.

The corporations are empowered to issue, in any grant or lease of the land, provisions binding the grantee or lessee to build in a prescribed manner, to repair and maintain the buildings, and they may prohibit any division of the site of the buildings or any addition to or alteration in their character without their consent. The cost incurred by the corporation in carrying into execution this act is to be defrayed out of the borough fund or borough rate or by money borrowed.

5. *The housing of the working classes act, 1890.*—This enactment is a modification and consolidation of all previous enactments. Large insanitary areas may be more effectively dealt with, and, as compared with previous practice, may be more economically acquired. Fifty per cent of the dispossessed must be provided for on the same site or in the neighborhood by the party displacing them.

England is remarkable for the part which municipalities have played in the housing question. In Liverpool, Glasgow, Huddersfield, Birmingham, and London buildings for working people have been erected and are stilled owned and operated by the municipality. The corporation of Manchester, so writes Mr. Henry Simon under date of April 2, 1894, is constructing a building, regardless of cost, for laborers' dwellings in the neighborhood of the remodeled property of the Manchester dwellings company. Dr. Alfred Hill, medical officer of health in Birmingham, in 1890 said that the council had then decided to erect twenty-two model workingmen's dwellings, more in the fulfillment of a promise than from actual need of houses. Financially it is not expected that they will prove a success. In Glasgow the larger part of the housing facilities furnished by the corporation are utilized by artisans; in Liverpool nearly one-third of the corporation tenements are occupied by the same class. The laboring element which most needs help has not received from municipalities anywhere the attention which one would naturally expect.

Lord Shaftesbury stated to the English royal commission that it was a very difficult thing in London to procure sites for building model dwellings. There was often an unwillingness to sell land for the purpose. He suggested that Parliament should have the right to condemn land for this purpose on the ground that the work was one of public utility.

In Great Britain we have the most complete example so far of intervention of public bodies in providing homes for the people. The result will be considered in detail later on, but we may consider them satisfactory, as there is constantly a growing taking hold of this branch of Urbanity by all the Municipalities of that country.

The principle of the right of public bodies to intervene in these matters is now thoroughly established and can never more be taken away, and the public are made familiar with the kind of municipal ownership, which will appear from the results to be a big step in the right direction—when every family is supplied with a decent home, this kind of activity will necessarily cease, and the liberty of those who desire to live in more luxurious habitations will certainly not be curtailed.

Before closing this branch of our subject we must mention the rent collecting and other private agencies for improving the housing of the poor.

Miss Octavia Hill was the pioneer in this business, she believes that the destructive and criminal classes can not be dealt with by any existing society or any building corporation, because the difficulty with these people is not financial but moral. They must be trained. This is what her system does, and there is no other method. The only way to deal with such people is to make goodness profitable. It is not a question of class, but of character. It is a question of personal influence, and the landlord or his representative is the one who alone can wield it. Miss Hill's statements are so important that extended mention of her methods of work is herewith presented. She insists that moral reformation is the only thing that can deal satisfactorily with the destructive class. If people will buy houses for the sake of managing them then they can get a hold upon such persons. That can not be done by a society. The management depends very much on judgment of character. You must notice when a man is doing better and when he is not, a fact which you can not bring up before a committee and prove it. Thus men must be held and at the same time a plan devised to gradually make them feel the benefit of the care that is being exercised over them. When old houses are bought a few improvements are made at once, such as putting the water supply and the roofs in order, but other improvements are added in proportion as the tenants' own care allows, and they become more capable of valuing and not abusing them.

A narrative of the circumstances which led Miss Hill to commence her work may not be without interest. One day, while attending a sewing reunion or some other church meeting, her sympathy was aroused in hearing about the woes of a certain woman. Impulsively she exclaimed: "I wish I had some houses to look after!" "Do you, though? Are you in earnest?" responded many of her friends. Shortly after, when dining with John Ruskin, she repeated the incident. He said: "Is it money or time you need?" She responded, "principally time." Whereon he replied that her case was hopeless. Ruskin ultimately said: "Go to my lawyer and have him buy three houses. They shall be in your hands. You can carry out your theories of visiting and rent collecting. If the money is lost, no matter. If you succeed, more will be forthcoming." At this time Miss Hill did not think much of the financial and practical sides of the work, whereas this is what Ruskin emphasized when he said: "If you can make it pay you will not only have plenty to do, but others will follow you." Ruskin's lawyer did not approve of so Utopian a scheme and tried to delay by finding objections against all property which Miss Hill suggested as eligible. Upon referring her suspicions to Mr. Ruskin, the latter authorized her to employ her own solicitor. She did so, and three small houses were speedily found, where operations were begun.

Miss Hill has not confined her housing activities exclusively to rent collection. Being an ardent lover of small homes as distinguished from tenement dwellings, she has built with her own money thirty-two cottages in Southwark, near the bridge which crosses the Thames, which she rents at a remunerative figure, receiving annually from 4 to 5 per cent dividend. The cottages are small but prettily disposed, with gardens in front, There is a large open space opposite where she has erected a hall for evening recreation, a gallery where women may sew and children play in rainy weather, and a room in which men may smoke and enjoy social intercourse.

Since Miss Hill started quite a number of private philanthropic societies have been formed for instilling into the minds of the poor a love for better homes by improving their surroundings in proportion to their appreciation of the same.

A proper understanding of the situation is grasped by most of these societies and is evidenced by the Edinburg Social Union by the following:

"The principle is maintained throughout of bettering the condition of the poor, not by lowering their expenditure on rent, which would merely tend to depress the rate of wages, but by giving them greater value for their money, and thus extending to them higher standards of comfort."

This is true political economy and needs no comment.

BRICK JOINTS.

THROUGH the efforts of the architects and manufacturers the brick industry has, of late years, shown a wonderful development, for it is but a comparatively short time since there was practically but one shape and color, and the only variation to be had was in the different degrees of finish. During the period when the pressed brick was in favor, it was unquestionably the desire of both the architect and the mason to avoid, as far as possible, all appearance of texture in a face wall; the bricks were made as smooth and regular as possible. They were bonded with "cut" headers, so as not to disturb the regularity of the courses, and the joints were made as fine and narrow as was possible, one of the essential qualifications of a first-class face brick layer being the ability to make the joints as narrow and inconspicuous as possible. Such work was at first laid in common mortar, made with fine sand, which allowed the bricks to be laid very close, but later the desire to have the joint still less prominent led to the practice of putting such coloring matter in the mortar as would bring it to the same tone as the brick. This practically obliterated the joint, and made a wall of a smooth, slippery, and as it has sometimes been called, "licked" surface.

This kind of masonery, says *The Brickbuilder*, necessarily lacked two essentials of most good architecture,—texture, and a straightforward recognition of the materials employed and the method of using them. Now, the construction of a brick wall naturally consists in laying courses of bricks one on top of the other, with a layer of mortar between each one, and it is consequently apparent that if we are to use our materials honestly, the joint of a brick wall should be recognized as an architectural feature just as much as the bricks themselves; and so soon as this is done we begin to get a surface with texture. It has been difficult to convince the mechanic, who was taught, when learning his trade, to obliterate so far as possible all trace of the joint, that comparatively wide joints of mortar of a different color from the bricks themselves could make a workman-like-looking job, and it is often hard work to bring a man who has served his time to sacrifice his principles so far as to follow the architect's directions, and lay a wall where the mortar joint is conspicuous, both on account of its width and color; but in many instances the mechanic has freely admitted, when the work was finished and cleaned down, that after all it had a certain merit and pleasing appearance, which was lacking in that which was done in the old way.

Besides recognizing the joint by means of color, it is also oftentimes desirable to use a greater width, particularly in the bed joints, which necessitates the use of a much coarser sand than was formely employed, so the bricks will not only stand up, but also stay in place. And if such work is laid in wet weather and a hard and non-absorbent brick is used, it requires some skill to keep the wall plumb and true, but

this difficulty can be overcome by the exercise of a little care and attention.

While the cement or coloring matter, which may be mixed with it control to a considerable degree the color of the mortar, nevertheless, the sand has an appreciable effect, and where it is desired to get a light-colored joint, the best sand for the purpose is a coarse, white beach sand, the only objection to it being that it is not as sharp as some bank sands, but this fact is not of sufficient importance, however, to interfere with its use. It was formerly quite generally supposed that the presence of salt in mortar was detrimental to its strength; it has been proved of late, however, that just as good mortar can be made with salt water as with fresh; and the government, on its most important works, as sea walls, lighthouses, and similar constructions, allows the mortar to be mixed of salt water.

It may be said that, as a general rule, a joint lighter than the brick is the most preferable, and a strong mortar of this kind may be made by starting with a pure lime and sand putty, and tempering it strongly as it is used with Portland cement. Care must be taken, however, in cleaning down a wall which has been laid with a wide joint of lime mortar, that the lime is not taken out by the joint to such an extent that the wall is whitewashed. If acid is used, it should be in very small quantities; but it is better to clean such brickwork with soda instead of acid, which, if the mortar if fairly well set, rarely starts the joints. It is also important that walls laid as described above should be laid so as to have ample time to become set before winter weather sets in. Care should also be taken to ascertain if there is any trouble liable to occur on account of unequal shrinkage in the mortar between the face of the wall and the backing. At one time it was often customary to lay the facing of brick walls, or at least a portion of it, in clear Portland cement, to allow the brick to be carved like stone after being set in place. There are instances where the unequal shrinkage or expansion of the different kinds of mortar made the facing scale off, and in time necessitated the removal of the entire outer 4 ins. of brickwork, but such trouble is undoubtedly less liable to occur with a wide joint in the facing, for in this case the joints of the facing and backing are more nearly equal.

Before the mortar between the bricks is set it is customary to "joint" it, that is to say, to compress it more or less by running an iron tool with a smooth surface along the joint, which compresses and at the same time indents the mortar. The jointer usually has a V-shaped edge which makes a sharp, narrow line, but sometimes a U one, which makes a slight indentation the full width of the joint. A good effect is obtained in some cases by simply cutting the mortar off with the trowel flush with the surface of the brick; but as this leaves a rough surface, the mortar is more liable to be affected by frost than where it is smoothed and compressed with a jointer. In jointing brickwork, where the bricks themselves are more or less irregular in shape and laid with a wide mortar joint, it is usually desirable to have the jointer run along the top of a straight edge, which is carefully leveled each time. Although the method of jointing the mortar may seem at first thought an unimportant detail, yet experience will soon show that it is a matter which deserves careful attention, particularly on work which comes near the eye, as in the case of fence walls, gate posts, and other similar work. If, when the architect is to build a brick wall where he wishes to obtain the best possible results, he will have several samples laid up with the same brick but different joints, he will find that the difference in joints may determine whether or not the wall is satisfactory in both color or texture, and also that a poor brick may be helped, or a good one injured, by the color and width of the mortar. The brick joint is a factor much more important than is generally supposed, and is worthy much more consideration than is ordinarily given to it.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

PRELIMINARY Sketch for proposed Phi-Kappa Pst Hall, Palo Alto, Cal., Havens & Toepke, Architects.

TEMPLE for Mission Lodge 169 F. & A. M., San Francisco, Cal., Herman & Swain, Architects.

TENDERS TO BE RECEIVED.

Treasury Department, Office Supervising Architect, Washington, D. C., June 16, 1897. Sealed proposals will be received at this office until 2 o'clock P. M. on the 22d day of July, 1897, and opened immediately thereafter, for furnishing all the labor and materials required for the excavation, sewer and temporary drainage, concrete and steel foundations for the U. S. Post Office, Court House, etc., at San Francisco, Cal., in accordance with the drawings and specification, copies of which may be had at this office or the office of the Superintendent at San Francisco, California.

Each bid must be accompanied by a certified check for a sum not less than 2 per cent of the amount of the proposal. The right is reserved to reject any or all bids and to waive any defect or informality in any bid, should it be deemed in the interest of the Government to do so.

All proposals received after the time stated for opening will be returned to the bidders.

C. E. KEMPER,
Acting Supervising Architect.

NOTES AND COMMENTS

A COMMUNICATION was received in June last from the Board of Regents, the Governing Body of the University of California, stating that it had been decided to prepare a programme for "a general competition for a permanent, comprehensive, and grand plan of the grounds and buildings of the University of California at Berkeley," and asking for suggestions with respect to the preparation of such programme. The matter was referred to the Competitions Committee, who have drawn up some suggestions which it is hoped will contribute to the successful issue of the Competition.—*Report of the Council of the R. I. B. A.*

WE DO NOT mean to assert that the business depression has borne more hardly on architects and draughtsmen than upon other classes, but when we consider the list of those who have become involved beyond the hope of prompt recovery, those who have felt forced to take their own lives, and those who have even yielded to the temptation to commit such "irregularities" as have brought them within the reach of the law, we doubt if there be any class of men which has suffered more. Besides this, the mortality amongst architects seems to be abnormal and we cannot help feeling that it indicates that the vital powers of resistance have been unnaturally lowered by the long strain and anxiety to which all professional men whose income is dependent on sporadic commissions have been subjected. During the last week, two more architects were added to the lengthening roll of the departed, Mr. W. H. Dabney, of Boston, and Mr. W. S. Fraser, of Pittsburgh. Mr. Dabney, born in the Azores, April 8, 1855, died April 29, leaving as the buildings with which his name will be most often associated, the Warren Chambers and the Trinity Court buildings, Boston, constructed while in partnership with Mr. H. B. Ball. Mr. Fraser, born in Ohio, July 19, 1852, died at Pittsburgh, April 27, after an active career of eighteen years in that city.—*American Architect and Building News.*

AND I END as I began, by impressing on you that no one can become a good architect who does not earnestly study what men have done before, who has not enthusiasm for his art to make him long and resolve to do nothing but what is good in its practice, and who is not ready to show that he has enthusiasm by the industry which surely attends it, and without which no study, no lectures, and no schools can be of any real service.

HE'S A BRICK.

WHEN a boy does something that is particularly good or noble his comrades say: "He's a brick!" for to call a fellow "a brick" is as high a compliment as one boy can pay to another, says the *National Builder*. If we stop to think about it, though, it seems rather strange that a brick should be chosen as a standard for measuring the worth of a boy. There is surely nothing very wonderful or fine about a brick. But, like a great many other sayings that do not appear to have much sense, we shall find, by looking up the origin of this expression, that it started out with a very sensible meaning. In order to get at its beginning, we have to go back into ancient history for a distance of nine hundred years before Christ—all the way back to the time of Lycurgus, the great Spartan ruler. Plutarch tell us that Lycurgus had a great many wise and curious notions as to how people should live and how the affairs of the country should be managed. One of his ideas was that there was no necessity for building a wall about a town if the soldiers were properly trained to protect the place. On one occasion an ambassador from a neighboring country came to see Lycurgus, and he asked how it was that he had no walls around the town. "But we have walls," replied Lycurgus "and if you will come with me I will show them to you." Thereupon he took his guest out upon the plains where the army was drawn up in battle array, and, pointing to the ranks of the soldiers, he said: "These are the walls of Sparta, and every man is a brick." So you see when the expression was used it had a great deal more sense than it has now.

BOOKS AND PERIODICALS

Circular of information of the NATIONAL ASSOCIATION of MANUFACTURERS, of the United States of America—in the February issue the annual report of the president contains many valuable suggestions upon the Tariff as well as the opportunities of improving our trade with China and other nations. He remarks that "in China, more than in any other country of the world, it is necessary to show actual samples of merchandise and machinery in order to create an intelligent impression upon the minds of the intending purchasers." The same might with truth be said of the South American trade.

LIPPINCOTTS' Magazine for June, 1897. Contains the complete novel, "As Any Gentleman Might," is a rattling tale of adventure by William T. Nichols. The hero is an American, but the action mainly in England, and the time is in the early part of the present century. Other short stories will well repay reading.

PROGRAMME of a COMPETITION for the selection of an architect for a New Capital building to be erected by the commonwealth of Pennsylvania in Harrisburg. This pamphlet is divided into four parts—first part giving the total cost $550,000, and terms of reward for those that compete. The second part gives the duty of the Board of Experts, etc. The third describes the plat of ground for the proposed buildings. Part four detailed requirements of the same.

OPPOSED TO CHEAP LODGING HOUSES.

AT a recent meeting of the Social Reform club of New York, Mrs. Josephine Show Lowell, chairman of the committee on vagrancy of the Associated Charities, took up the question of cheap lodging houses. She regards them as, in the end, a bane and no boon. They foster the spirit of vagrancy and irresponsibility. They bring those who have no desire for a higher standard of living into successful competition with the men who have families to support. They really operate to lower wages. For the care of really homeless men she advised the establishment of municipal lodging houses, where the strictest investigation could be given to each individual applying for help. By such means she would deem it possible that deserving men with homes in other cities could be returned thither, actual vagrants committed to the workhouse and young beginners in the life of vagrancy referred to private charity, with some hope of successfully wooing them from the nomadic life so dangerous to the community.—*Industry.*

THE RIGHTS OF THE LOWEST BIDDER.

AS AN illustration of what it considers the rights of the lowest bidder, the *Bulletin* cites the case of a contract for a bath-house for the City of Boston, which was awarded to a contractor whose bid was considerably above the lowest, by order of the Mayor, who had made the award, as he explained afterwards, in consideration of a private promise from the contractor to employ only union men on the work. We need hardly say that no architect was concerned in the Mayor's action, and the whole profession will support the claim of the Boston Master Builders' Association, as set forth in the *Bulletin*, that if a promise to employ none but union men was to be an element in the award, the lowest bidder should have been allowed to make the same promise, if he wished. It is obvious that a case in which known skill, distinguished honesty, or even personal friendship are allowed to count in determining the award of a private contract is a very different thing from one in which the award of public work is made in accordance with a concealed bargain, to which only one of the bidders is admitted. In the former case, the reputation of the different bidders, and usually, the friendship of the owner for any of them, is known to all the bidders; and every one who estimates does so with an understanding of the possible odds against him; but in the latter case the bidders who estimate in competition with the favored contractor have been deceived, inasmuch as the legal reservation of the right to "reject any or all bids," which is manifestly intended to protect the city against irresponsible or vicious contractors, and the application of which, in selecting a contractor, can be reckoned on with reasonable certainty by the bidders, has beed used to justify the award of the contract in accordance with considerations which the bidders were not informed of, and could not have inferred from any circumstances known to them.—*American Architect and Building News.*

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street

SETH BABSON, Pres. W. P. MOORE, Vice-Pres.
OLIVER EVERETT, Sec. JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

THEO. A. EISEN, Pres. ARTHUR B. BENTON, Vice-Pres.
WILLIAM C. AIKEN, Sec'y. AUGUST WACKERBARTH, Treas.

WASHINGTON CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

JOS. C. HORNBLOWER, Pres. JAS. G. HILL, Vice-Pres.
E. W. DUNN, JR., Sec. W. J. MARSH, Treas.

ASSOCIATION OF ARCHITECTS OF ARIZONA, meetings held at Phoenix, Arizona.

D. W. MILLARD, Pres. T. H. MADDOX, Vice-Pres.
W. R. NORTON, Sec. and Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.

E. J. MOLERA, Pres. W. F. C. HASSON, Vice-Pres.
OTTO VON GELDERN, Sec. EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.

JAS. E. BRITT, Pres. J. L. E. Firman, Sec.

BUILDERS' EXCHANGE, Directors meet first Friday in each month at Mission and New Montgomery.

OSCAR LEWIS, Pres. JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday evening of each month.

ADAM BECK, Pres. M. V. BRADY, Sec.

AMERICAN STEEL IN EUROPE.

AT the annual meeting in London of the Iron and Steel Institute this week American Competition was one of the chief points of discussion. President Richard Martin spoke of the enormous output of the leading American streel works, and pointed out that the Ameticans were outdistancing the British in the uses of steel. He instanced the steel buildings being erected in nearly all the large cities of the United States, and urging lower freight rates, saying that the present cost of transportation was severely handicapping British industry, as the rates not only in America, but in Belgium and Germany, were greatly below the English rates.—*The Age of Steel.*

TROUBLE AT THE MILLS.

LAST MONTH a large number of the mill men and loggers in the Mendocino county mills refused to work at the prices prevailing and under the ruling system of payment. This move at the present time is a very unfortunate one, for it is well known that no line of business is so depressed as is the lumber trade at this very time, says *Pacific Coast Wood and Iron.* Mills have been run at a loss for a long time and mill owners have kept their men at work to prevent, as far as possible, starvation and entire stagnation. Especially have the redwood interests suffered. The great influx of pine, spruce and fir into this market has literally driven redwood from its stronghold and in order to sell it at all, prices have been reduced so that no mill man receives for the product of his mill, no matter how cheaply it is manufactured, a fair equivalent for his capital invested or his labor. Mill owners and all the employes have but one common interest and the laboring man should bear in mind the fact, that although he is working for low wages his employer has had his income reduced and is really working for nothing, besides seeing his forests stripped of the finest timber which can never be replaced. Politicians, for the sake of glory, may force bills through the legislature that hamper and oppress mill owners but mill owners cannot perform impossibilities, and if worst comes their only relief lies in shutting down their mills and closing the doors of their stores and letting the employe go to other lands already overcrowded with laborers. The prospect in Mendocino is very dark.

If the laborers insist upon carrying out the strict letter of the Stanford Law, trouble will ensue that is apt to crush not only themselves but the mill owners, and with them the whole State must suffer. In these times of hardship all should unite to bear the burden, and the load will be made lighter as it is divided; each man lending his help until the time comes when the clouds will grow brighter and the era of prosperity dawns. Then will be the time to ask for and obtain better prices for labor and for lumber. With a greater demand for redwood we feel assured that every mill owner will gladly divide his gains with his employes and rejoice that he is able to do so. The following article from the Fort Bragg *Advocate* shows the effect on that town of the strike. The stoppage of the mill shuts off the electric light and the town is in the darkness in more ways than one: "The mill and woods are still closed down, and no one seems to know when operations will be resumed again It may be in a few weeks, or not for a year. The company has had a hard time to get along the last few years, and just at present the members of the concern are in such a mood that they don't care whether a wheel turns or not for the next twelve months in the mill here. As Fort Bragg is a saw mill town in the strictest sense of the word, with no ordinary industry to back it, it is sincerely hoped that the little unpleasant difficulty at present existing will be speedily settled."

ROADWAY ALONG THE ROCKY SHORE AT TIBURON

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Courts of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

THE SPECIFICATIONS ARE AN ESSENTIAL PART OF THE CONTRACT.—The specifications are an essential part of the contract, and as material as the price of the work or the terms of the payment, where the contract price is not to be paid until the work is completed according to the specifications. It is not indispensable that the specifications be signed by the party to be charged, but it

will be sufficient if they are referred to with certainty. But where the reference is false it cannot be helped out by oral evidence.

Thomas Donnelly, respondent; Frank P. Adams, et al., appellants. Foreclosure. Reversed. S. F., No. 182, Department Two, Filed November 27, 1896.

When Market Value of Materials Cannot be Shown.—In an action against the owner of a building for materials furnished for and used in its construction, the architect cannot testify as to the market value of the materials where the price has been fixed by the contract of purchase.

McCormick v. Sadler, Utah, 47 Pacific Reporter, 667.

Construction of a Warrenty of Bricks.—A sale of "common bricks" to be of "good quality and equal to sample" involves no implied warranty that they shall be fit for the purpose for which they are purchased, although the seller is informed of such purpose.

Wis. Red Pressed Brick Co. v: Hood, Minn., 69 Northwestern Rep. 1091.

Limitation on Building Bond.—A material man cannot sue on a building contract bond which names only as beneficiaries the owner and any person advancing money to the owner to be used in the construction of the building.

Macatee v. Hamilton, Texas, 38 Southwestern Reporter, 530.

Right to Retain Installments.—A building contract provided that the owner might retain from installments as they came due sufficient funds to pay all claims against the contractor due and unpaid, but that such provision should not impair any rights under the contractor's bond. The court held that the right to withhold payments was intended as a protection in addition to the bond, and not as applying only to the final payment.

Dempsey v. Schawacker, Mo., 38 Southwestern Reporter, 954.

BUSINESS MOSAICS.

Rissmann's Rafter and Polygon Guage will give the length and cut for each and every rafter required for roofs of eighteen different pitches, including mitre cuts for planceer, crown moulding, facia, mitres for different polygon, etc. All you require to know is the width of the building and the pitch you desire to give roof. The guage is made of heavy card board, size 11"x13", and is to be fastened onto a board of same dimensions, and with the use of an ordinary carpenter bevel the above cuts may be obtained in an instant.

Price 35 cents postage paid. Agents wanted in every State. F. Reissmann, West Point, N. Y.

Aunt Hannah—Silas, what be filibusters? Silas—Why, they be men what bust in Philadelphy, I guess.—*Examiner*

Bradley Bros. manufacturer Cement Laundry Trays, made of the best Portland Cement and guaranteed not to leak, crack or sweat. Office and factory 53-57 Tehama street, San Francisco.

Portland Cements of the best and most reliable brands can always be ordered from W. R. Grace & Co., 203 California street, San Francisco.

Bender—Miss Styles asked me to call again. Fender—Oh, indeed! What firm are you collecting for now?—*Yonkers Statesman.*

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

SOME YEARS ago Congress passed a law giving the Secretary of the Treasury the power to secure designs for public buildings by the competitive method. This law was the result of much labor on the part of the Architectural profession exerted both individually, and collectively through the American Institute of Architects, and it was confidently hoped and expected, that a marked and beneficial effect would be the result on the artistic and utilitarian character of future constructions. The profession had every reason to expect such a result from the new departure and were bitterly disappointed to learn that the then Secretary of the Treasury interpreted the law to be optional with him to enforce or ignore, and that he was graciously pleased to ignore the desire of the people to inaugurate improved methods in the conduct of the office of the Supervising Architect, which were designed to secure for the benefit of the nation the talent, abilities and genius of the leading men in the noblest of all arts, the art of building.

The present Secretary of the Treasury has reversed the action of the former incumbent (and incumbrance) of this high office, and put in active operation the provisions of the long neglected law enacted by Congress and approved by the President on the twentieth of February, 1893, and formulated regulations governing the competitions.

Under these regulations at least five architects of good professional standing, and who are citizens of the United States will be requested by the Secretary to submit competitive plans, specifications and drawings for each building to be be erected, the merits of which will be investigated by a committee consisting of the Supervising Architect of the Treasury and two architects or experts in construction, who will report to the Secretary for his approval. The architect whose designs are accepted will receive in compensation for his full professional services, including local supervision of the building, a fee computed at the rates of 5 per centum upon all sums up to $500,000, 3½ per cent on the nex

$500,000, or any part thereof, and 2½ per cent upon any excess beyond one million dollars. The department, however, reserves the right to reject any and all plans.

This departure will certainly cause an increase in the interest of the general public in the beauty of their public structures and lead to a healthy rivalry between the various cities, which should react beneficially on the character of our private architecture as well.

WHAT IS AN ARCHITECT?

E CAN define with reasonable accuracy the physician, the surgeon, the attorney, the artist, the sculptor; but the architect has so many sides to his completeness that it is well nigh impossible for a single mind to work successfully on all the lines which he is now supposed and expected to bring into action. If he could but cut himself away from some things now required; if he could but "press the button" when the inspiration of the sketch is given or when the drawings are perfected and let some other fellow do the rest, we might be able to handle him more readily. But now, through the long tedious and wearying process from the sketch to the final certificate, which is the architect? Is he the plansman, the designer or the specification writer? Is he the man who sees the bricks laid and the nails driven, or the man who cuts down the extra bills? Or is the true architect just the man who gets the job? Is he the artist or the hustler?

Is the soul of his endeavor to be found in the completed work or in the battle for an opportunity? We cannot tell you. Sometimes he is one thing, sometimes another, and each phase of his many sided character has some example stalking in our midst and honored in our motley procession; let us take him as we find him, and help him to what he may be, regardless of his complex nature.

The above is from a report of one of the committees to the last Convention of the American Institute of Architects.

When we find architects themselves not able to define an architect we can condone more readily the lack of the knowledge of what an architect is and what he has to do on the part of the Laity or general public—and their lack of appreciation as to his worth and his labor.

Just a glance at his multitudinous knowledge may open the eyes of the people to the amount of education required to become a worthy member of that, without exception, noblest and most difficult of the professions.

The list of arts and sciences an architect has to have at his fingers' ends, is very formidable. Acoustics he has to be very conversant with otherwise the auditoria he designs will be failures. Arboriculture, Horticulture and landscape gardening he has to be acquainted with, for often he is called upon to oversee the laying out of the grounds around the mansion he is putting up or around some large public building so that all may harmonize. The knowledge of Archeology and History are also some of his necessary accomplishments for little could he design without a vision of old buildings, without a knowledge of the History of Architecture.

Boxing is an art to which he should not be a stranger—to defend himself against some truculent contractor when he insists upon him doing what is right and according to contract, or against an owner who believes that he, said architect, has prepared plans, etc., for him just for the benefit of his health and to keep his hand in, when he asks him, the owner, to pay what he owes.

When he comes to choose the best materials for the several parts of his buildings Chemistry and Mineralogy, Metallurgy and Geology have to be thoroughly digested—and when his materials come from the vegetable kingdom—Botany. Imagination and design he has to be blessed with and the art of drawing, by which he makes these known to others. Educational methods and Pedagogy he has to be grounded in when he puts up colleges and schools and Ecclesiology when he designs churches.

The science of Ethics as it enters into the complicated and delicate relations of architect and client, architect and contractor and architect and craftsman as well as the relations between architect and architect has to be referred to more frequently perhaps than in any other relation in life, for without a scrupulous attention to its codes no true architect can be.

Law, although theoretically out of his province, practically he has to have a smattering of; both in regard to the relations above mentioned, and in getting out the numerous legal documents and filing the same required during the preliminaries to building and at other times during its progress which his client more often entrusts into his hands than into the hands of his lawyer.

He has rlso to be *au fait* with all the latest styles and articles of furniture of the several apartments, with Gastronomy in laying out a dining room to best suit proper digestion; with Cookery in arranging the kitchen—and with what may be called Dormitonomy for the sleeping rooms—not forgeting music when arranging the apartments for the art which is the liquid form of architecture.

Finance must not be a stranger to him, for has he not to make very often $3.00 out of $2.00 or in other words make $2.00 go as far as $3.00. Has he not also to make five per cent commission provide for himself and family after paying draftsmen, stationery, office rent and the thousand and one little outgoings necessary to get a job and keep it.

Hydraulics and Hydrostatics, Pneumatics, Electricity and Physics he must have graduated in to specify and lay out intelligently all the wires, pipes, etc., necessary for a modern building.

Languages must not be neglected by him for there are many technical treatises in foreign languages which he ought to be able to read in the original to keep *en rapport* with advanced ideas.

Mathematics must be to him an open book—for has he not to understand and work out all the formula necessary to find the strains in and strength of his materials and that branch of it, Geometry, has to be as familiar to him as A B C when making his detail drawings.

To be able to specify the materials and labor and to direct construction he is supposed to know even more than the skilled mechanic about the arts and crafts connected with buildings which includes nearly all in some shape or manner.

Machinery in arranging for boilers engines, etc. Mining when making excavations for deep cellars tunnels, etc.—transportation, steamfitting for heating apparatus, locksmithing, carpentery, painting and even the proper way to do the humble trade of Kalsomining, and so on and so on with a list which would take up too much of our pages to complete.

He must know as much about Hygiene as a physician to be able to put up a healthy home or healthy place where humans congregate; and something about practicable Therapeuties and surgery to build hospitals rightly, also know something about Penology to build an appropriate prison.

Turning to the fine arts he ought to be able to paint and to model, and to aid him in the composition of his ornamentation he must use subjects from the animal and vegetable kingdom when an inkling of Zoology and Botany comes in handy. In the adaptation of ancient art, a proper understanding of its motive cannot be obtained without a knowledge of Philology and Mythology; and a practical insight into the Theatrical profession is needed before he builds a theatre.

Then he must build his buildings to be able to withstand cyclones, earthquakes and other like natural phenomena and to suit the climate, so that Meteorology is necessary to teach where these phenomena chiefly occur and the climatic conditions of the place he has to build in.

To write his papers which he occasionally reads before scientific and popular bodies—to make out lucid reports and descriptions, even to write a creditable specification he must be somewhat of a Litterateur.

And finally to have the chance of exhibiting his skill at all he must have studied Hypnotism, Animal Magnetism, Bon Mots, Divinity, Physiognomy, Practical Politics and what not; not forgetting that he must be a bon vivant and a gallant; to make a success he also must be a consistent hypocrite and a time server.

To exhibit what we mean by the ignorance not only of the general public, but of those who come in contact with plans and architects, we cull the following from a San Francisco journal which we have just come across. In describing the half-tone photograph of a cottage the author says:

"The exterior view, which your architect calls the 'plan of elevation,' is a departure from the set and inartistic lines of your cut-off-of-the-same-piece, ready-made dwelling, and as a whole is imposing and extremely attractive.

"The illustration is made direct from a photograph, so that it is a faithful, reproduction of the house itself; and not an ideal creation of a clever draughtsman."

Here we have a terrible jumble of mistatements—what architect (God save the mark!) could the author have come across that calls a perspective view a "plan of elevation"—and then to put the title in quotation marks to show that it is your architect's term! With all due respect for the author, we don't believe he ever heard any architect say such a thing, or if he did, he must have been playing on the credulity of his listeners, vulgarly called joshing him. Then the remark in the last paragraph, although not saying so, leaves an impression that clever draughtsmen's ideal creations are meant to deceive, in comparison to the *faithful* reproduction of the photographs. Here the writer labors under the impression that it only requires *a clever draughtsmen* to make an ideal creation. Of course those initated knows that it requires a *designer* who is called an architect when the result is a building. They also know that the ideal creation of an architect drawn on paper, when carried out in a building is the facsimile of its paper original and looks exactly like it as far as a solid can look like the same drawn on the flat.

We cannot altogether blame the public for these popular fallacies, they are not able to distinguish, with the little enlightenment they have on the subject, between an architect and a quack who hangs out his shingle and advertises himself as an architect.

So it seems the only way to educate them is for the architectural journals and the newspapers to keep digging away and showing up and explaining all these misapprehensions which are constantly showing themselves.

PLUMBING GOODS.

IN LOOKING over the progress of the art of plumbing within the last few years the improvement in that art is more evident than in any other of the building arts. It has bloomed out into what we must call the Art of Sanitation for want of a better name. The actual plumbing in the sense it was used some twelve years ago now is supplemented by several other branches of the building trades or crafts, which connot be considered apart from it, and we find that the whole character and adaptation of plumbing and sanitary fixtures has been almost entirely changed. Instead of the woodwork, sometimes elaborate and expensive, covering up the fixtures and pipes, the bath rooms are now tiled, with all the fixtures open and finished in every part, thereby insuring not only practical usefulness, but cleanliness; nor has this change stopped at the bath room—it has extended to the kitchen, the butler's pantry, the scullery, the laundry and indeed to all parts of a building where sanitary fixtures are used. Both in the kitchen and pantry, and in the scullery, the sink set in woodwork (a harbor for dirt and vermin) has been replaced by the tiled wall with an open porcelain sink and hinged drain boards. In the laundry, with the exception of the portable wringer base, woodwork has been entirely gotten rid of; and so it is, all through, in both public and private buildings. All the large first-class hotels, as well as fine private dwellings, have tiled rooms with porcelain baths and all open fixtures. In the new hospitals and asylums all the baths, water closets, sinks and special fixtures are made of glazed ware and in the large office buildings open fixtures, in lavatories, water closets, urinals and slop sinks, are altogether adopted.

In the sanitation of public institutes progress has been still more marked—school boards now look well that they get the best sanitary fixtures for the schools, and public baths, gymnasiums, asylums, barracks and prison, are now fitted up far more sanitarily than a few years ago.

In private dwellings it is a fact that plumbing fixtures are now recognized as of equal if not of paramount importance to the general furnishing of a well-appointed house and it has become the almost invariable custom for parties building or remodeling to visit show rooms and select their fixtures, fittings, etc. When this can be done, it is in every way the most satisfactory method.

Again in former time the fixtures were selected haphazard and no attempt was made to harmonize them with the surroundings—now the architect has to see to it that the style of plumbing fixtures accords with that of the apartment in which they are placed—or vice versa. For example we find bath rooms fitted up and finished in one style Colonial, Renaissance, Rococo, Empire or whatever may be chosen.

We have been lead somewhat into this line of thought by the perusal of the catalogues of large plumbing goods firms, and more especially the magnificent volume lately issued by the J. L. Mott Iron Works, which is verily an *Edition*

de Luxe, and reflects in better degree than words the strides which has been made in that line. It is a volume of 348 pages every one replete with illustrations of articles of use and benefit to the human and animal races.

It opens with interiors of completely fitted up bath rooms. The carpenter has been now relegated to other parts of the building—the doorways being sometimes the only evidence of his existence; all the interior walls, floors and ceiling being clothed with glazed tiles.

The amount of fittings going to make up the furniture of a bath room are now quite numerous—first of all there's the bath tub itself—until a little over two years ago all Porcelain baths were imported, and indeed were considered a great luxury, only to be enjoyed by the very wealthy; to-day they bid fair to take the place of all others except such as are used in the cheapest class of buildings. The reason for this change are not far to seek for there is nothing to compare with them as regards cleanliness and durability. It is simply the perfect bath, besides which all others, such as metal or iron enameled, are commonplace and in the end really more expensive, as they wear out and have to be replaced from time to time, while the porcelain is always the same; it never changes or discolors; when wiped out with a sponge it is as white and pure a china surface after fifty years' use as when first put in. Indeed, the saving of labor in the simple matter of keeping clean is a most important feature, and one which is particularly appreciated by the large first-class hotels, where hundreds are being put in one building. As a matter of course, in all the new hospitals nothing else is thought of, and in the old institutions the old metal and enameled tubs are gradually being replaced by the porcelain.

Nor is our progression alone in the quality of the ware, but also in design, which now present, instead of the heavy, clumsy, angular vessel as first imported, a graceful and artistic bath tub, the sides and shape of which lend themselves to the most refined artistic and delicate decorations.

Some of the newest designs are made so that the tub sets flat upon the floor instead of being raised upon legs—this style would, we should imagine, in a short time supersede the raised, for it has two very great advantages, one in lowering the tub so that the user can step in and out easier and the other the benefit of doing away with the space under the tub which is liable to be neglected and to get dirty and requires more labor to keep clean. To the tub there are required a number of accessories outside of the supplies and wastes. These are generally made of metal work and finished in nickel-plate as being the most durable.

First among these are the shower and needlespray, which may be fitted onto the tub or onto the wall back of the tub, or it may be entirely separate and have its own receptor to receive the water.

Towel racks and sponge holder are usually screwed to the wall by the side of the tub, while the soap dishes are made portable and so that they may fit onto the roll rim wherever desired.

Second, a seat bath is a most desirable appliance in a bath room serving as it does, the double purpose of seat and foot bath. These are made now with a wave spray from the back as well as the ascending douche.

In hospitals and asylums a light bath tub which is comparatively low and broad, features which facilitate and render convenient the bathing of the patient by the attendants is the most desirable, and one on castors or on a cast iron carriage with swiveled axle and wheels with rubber tire cushions, to allow of the bringing up the same to the bedside.

The most convenient lengths of bath tubs are 5, 5½ or 6 feet, however in some places, e. g.—in yachts and cars these would take up too much space so some are manufactured 2½, 3 and 3½ feet long and symetrical at the ends.

We have not space now to go into the merits of the innumerable supply and waste fittings. As before stated the generally received best material for these is brass, nickel plated, both nickel and silver plate wears off in time, so that some solid untarnishable presentable metal is the ideal. The Mott Company have a metal which they call Crown White Metal which they claim has these advantages, as being solid it will always retain its luster and brightness, no matter how much it may be cleaned.

For a complete bathroom the following are required:—

1st—A place for clean towels, which may be in the form of a shelf of metal grating, a shelf with rack below, a rack only or a towel horse. A rack may be single or triple fixed against the wall or folding like a gas bracket. The advantage of the horse is that it is movable.

2d—A receptacle for soiled towels—this is made in the shape of a metal cylindrical basket about 20 inches high.

3rd—Robe hooks for the hanging up of the bath robes, either single, double or triple.

4th—Sponge holders—these again have a number of varieties, they may be made entirely distinct from the wall being carried on a bracket, and circular, they may be in contact with the wall when an oblong basket, sometimes in shape of a fire grate, is used, or they may be portable so as to hook on to the roll of the tub. These latter are made also with a soap dish below forming a combination sponge holder and soap dish.

5th—Comb and brush racks—the best being those forming a narrower edition of the oblong sponge holder already described. A narrow metal shelf is also handy for combs only.

6th—In hospitals and sanitariums a bath thermometer is required, made with a handle so that they may be immersed in the water.

7th—Although not an absolute necessity a bath seat and head rest are very desirable adjuncts to the bath—it consists of two nickel-plated clamps engaging the rim of the tub, and connected by a flexible band five inches wide. This band can be slipped back and forth through each clamp to attain any desired height of seat or rest, and when adjusted is held firmly in place. It thus makes an admirable seat, being soft and flexible, and the same is true of it as a head rest.

8th—Soap dishes—these again are made in numberless varieties, either to go against the wall or to attach to rim of bath or entirely separate so as to place on slab. They may be made of china ware or of perforated nickel plated brass, the latter may be used for a small sponge also, and appears preferable because allowing the water to drain away and keeping the soap or sponge dry.

9th—Metal holders for shaving mug, tumbler, tooth brush vase are very handy as they serve to keep clear the slab of the wash stand. These are made of ornamental open work, plated brass, on brackets fastened to the wall. The same end may be attained by the provision of a plate glass shelf to receive the articles mentioned above.

The following is a most convenient and sensible arrangement of lavatory appliances. Holders for soap dish, tooth brushes, tumblers, sponge, comb and brush are attached to

the marble back, and each has its particular place, so that the slab is entirely unencumbered.

Finally other necessary fittings are match boxes or holders, and where the water closet is placed in the bath room paper holders of many kinds to which may be added a cigar holder.

The forgoing list indicates the pitch of convenience and luxury attained in the end of the century bath room.

After the bath the lavatory or wash basin claims our attention.

There is no part of our sanitary department that warrants more careful or more special attention than that of lavatories. The evolution from the cabinet wash stand with its concealed pipes and woodwork, often elaborate and expensive, to the highly sanitary and beautifully artistic work now in vogue must appeal to all who may be in any way interested.

Of lavatory slabs a far larger range of choice can now be had than ever before—they are now designed in onyx, in statuary or imported marble such as Numidian, Rose Josper, St. Baum, etc. In regard to the fittings the same may be said, and again in basins which can be had in Cauldon China and earthenware decorated or plain, oval or round. The superior convenience of the oval shape has caused it to supersede the circular form in all but very cheap work.

In the designing of lavatories a greater scope for variety is obtained than in bath tubs and the many beautiful designs in the catalogue already referred to prove the statement.

The designing of the waste and overflow so as not to interfere with the interior of the basin, has always been a hard problem to inventors. The best solution we have seen so far is in the Purita, Utilis and Nassau basins. The salient features of the Purita basin are a deep bowl, large overflow with movable metallic strainer, and a plug or stopper operated by a direct lifting motion. The stopper or plug can be lifted out, giving access to the waste and overflow.

The plug and chain comes in the way and is difficult to keep clean and the same objections obtained in most other devices: these objections are minimizedin the Purita—for the bowl is free from obstructions save the slight circular projection of the overflow at the back of the same. When a combination tap in used and placed over this projection it appears as if the minimum of obstruction has been attained consistent with hygieneity.

In the matter of basin traps, the old lead trap no longer is admissible, and nickel plated brass is the material in vogue. Out of the many traps on the market the most sightly appears to be the Elliptic Cast Brass trap, shaped like a whisky flask with a mouth at both ends.

Another sanitary appliance of even greater importance than those already mentioned is the water closet—the marked changes and improvements made in this department since a time even as late as 1888 would seem to call for some special notice at this time. These changes and improvements have not been altogether confined to the mechanical perfection of water closets as sanitary fixtures but what is artistically beautiful and pleasing to the eye, with a view to unity and conformity of design.

There are several classes of water closets—the Syphon Jet are particularly adapted to the best class of private work. The wash-out form is appropriate particularly for public use, represented by the Inodorso. The wash-down closet is well adapted for both private and public use and one of the simplest and most direct. The pump closet for use on ships, yachts, houseboats, launches, battleships, etc.

In ranges of closets for office buildings, school houses and other public buildings, the same marked improvement has taken place within the last few years. Woodwork is now altogether banished and the partitions of water closets and urinals made of marble or slate fitted into nickel plated brass stall frames, consisting of post and top and bottom carrying pieces from wall to posts. The walls and floors are usually of marble and the partitions stand clear of the floor.

One of the little details considered almost indispensable now in public water closets and railway cars and useful even for private bath rooms, is the Indicator, showing whether the room is occupied or not. Indeed, to our mind, they afford such relief from embarrassing situations likely to occur that it will soon be considered an indispensable attachment where a closet or bath room is in general use, or used by more than one person.

The swinging chain for the pull will soon be superseded by the guide rod which fixes the pull in one place and ensures always a direct vertical pull on the crank of the cistern.

Before we leave this part of the subject, we hope that it won't be long before street and park conveniences come into use in the large cities of this country as they have long ago in Paris and London, and other European cities.

We will now briefly glance over the progress made in plumbing fixtures for culinary and household purposes. It is now recognized that these fixtures have to be as fully hygienically made as those of the bath room, and so we find in use fine white porcelain slop sinks without any woodwork whatever, and fitted with cisterns and flushing pipes. That variety used for hospitals called the clinic sink is made so that the supply is operated by a foot valve obviating the necessity of touching the fittings with soiled or bloody hands.

In no department is the great advance more marked than in kitchen sinks. We have managed not only to get perfect form, but have also succeeded in glazing the outside, front and ends; this, together with the porcelain back and porcelain legs, leaves no part which is not impervious to moisture. Furthermore, strength and durability are assured by the substantial thickness of two inches. Heretofore the backs have always been made of marble, now often of Imperial Porcelain. It is unnecessary to call attention to their great superiority to marble, as it is well known that the latter will stain and absorb grease, while the porcelain back is non-absorbent and simply requires to be wiped off to be perfectly white and clean. The Imperial Porcelain legs constitute a distinct novelty and improvement. They require no care or labor to keep them clean and polished, and being white, the same as the sink, they impart to the combination an element of nearness and brightness unattainable with the metal leg.

A drain board is an important adjunct to a kitchen sink; one has been specially designed for roll rim sinks, which fulfils all practical and sanitary requirements. It is entirely free from the wall, one end being supported by the sink and the other by cast brass brackets or a leg. The corner drain board swings on the hinges fastened to the wall. The end drain board swings on the hinges at back, the supporting leg being telescopic so that the board can be swung up out of the way when it is desired to clean the sink, wall, or when not in use. The board is made of pieces tongued and grooved with rods passing through to insure non-warping. The rim along the three sides of the board prevents dishes falling off, also water from dripping to the floor. At the point where the board rests upon the sink, there is placed a row of rubber fenders to protect the roll rim from damage. Where the board drains into the sink is affixed a downwardly projecting nickel plated nosing, thus insuring all

water draining into sink. Each drain board is furnished with an automatic catch to hold it up against the wall when raised. They are entirely free from the wall.

For pantry sinks the whole is covered with a marble slab the ends forming drainers with countersinking therein, this again does away with all wood around the sink.

A very useful adjunct to porcelain and metal sinks is the mat to be placed at the bottom of sink or upon top of marble slab. They serve the double purpose of lessening the risk of breaking china, and when used, particularly with kitchen sinks, will prevent the scratching and discoloring of the bottom by careless placing of pots, etc , therein. The mat consists of hardwood slats firmly held in place by brass rods. They are more or less flexible.

Another very advisable adjunct is the grease trap.

Directing our attention now to the laundry—porcelain ware, with its substantial thickness, fine glaze and beautiful appearance, is the ideal material for sanitary wash tubs. Iron, cement and soapstone are other materials used, but for the best work porcelain will maintain its ground.

The only objection to them ever raised being the openings between the tubs, which allow water to fall to the floor while clothes are being transferred from one tub to the other; also the difficulty of obtaining a substantial hold for the wringer. These objections are overcome by a wringer base, to which the ringer can be quickly attached by the laundress in a thorough and substantial way, and which drains into the tub on either side. By turning a thum-screw, the ringer base can be removed, while all parts of the tub are accessible for cleaning.

The legs are furnished with adjustable iron frame extending from each leg to wall, thus making a firm and permanett support for the tubs. The porcelain backs are non-absorbent and will not discolor. They project down into the tubs so that nothing can splash and run down behind. With the tubs and the Imperial porcelain legs, they present an all-white surface so desirable in all fixtures of the kind.

Another sanitary problem is the public drinking fountain. The ordinary drinking cup in public schools, parks, bicycle paths and other public places is frequently objected to because it may lead to the spread of contagious diseases. To obviate any danger of this kind, the Purita drinking fountain has been devised. Water enters the drinking cup through the controlling valve, which can be set so as to permit the water to bubble up in a small jet to the desired height. In this way the child or other person can drink of running water, but cannot touch the cup, thus avoiding all danger of contaminaion. It will take some time however for a person habituated to drinking out of cups to get used to this habit of drinking although it is the most natural.

WHAT CO-OPERATION HAS DONE.

MAN has colonized this planet, and century after century, for thousands of years, he has striven to mold to his use the flora and fauna of the globe. He has given some attention also to molding himself and his relationships says the *New Time*. He made a splendid move when he nationalized and democratized defence and the administration of justice. He will make another grand advance when he nationalizes and democratizes industry. In the earliest times, when each one defended himself unaided, it took the whole life of a man for warfare and the training and preparation it required. But after a while men said: "There's a better way than this. We'll form ourselves into a nation, and guarantee safety to every man, and put the whole power of the State behind the promise. Then a few men with guns will be able to keep the peace for all, and a vast amount of vigor and time will be saved." And they did, and the energy thereby released has developed the commerce and science of modern times. The material civilization of the nineteenth century is the result of the nationalization of defence, and the equalization of safety. So it will be with the nationalization of industry and the equalization of security from hunger and cold; the larger part of the time and attention devoted to getting material wealth will be given to higher pursuits, and the twentieth century may see a civilization of the soul, a spiritual development as magnificent as the materjal advancement of the nineteenth.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

BOOKS AND PERIODICALS.

Year Book of the SCHOOL OF ARCHITECTURE, University of California, published by the Architectural Society, 1897. This handsome pamphlet contains a list of the members of the Architectural Soc ety as well as a list of the officers of the same. The work is fully illustrated with drawings of the students from problems given as directions in regard to the design required, many of these are very meritorous and do credit to the students as well as to the University.

A Mountain Moloch by Duffield Osborne is the complete novel in the July LIPPINCOTT'S Magazine. In addition the list of articles are of unusual interest and well worth the price of twenty-five cents.

Sixth Annual Report of the BUREAU OF LABOR, STATISTICS AND MINES to the Governor and Fiftieth General Assembly of the State of Tennessee, 1896. Nashville: Franc. M. Paul, printer to the State, 1897.

This report is fully illustrated by half-tones, and maps; coming as it does at a time when the strike of the coal miners is attracking the attention of the country. The following extract from a letter of M. Wood of the Commission, will be of interest:—

"The growth of Tennessee as a mining and industrial State, as exhibited herein is very encouraging. The figures show that the total value of her mineral products in 1896 was the largest in the history of the State, and it is gratifying to note the material improvement in the physical condition of the Mining properties in the State. The decrease in the number of accidents over the previous year is very appreciable, notwithstanding the large increase of production."

INEXPENSIVE COUNTRY HOMES, a practical book for architects, builders, and those intending to build. A handsome cloth-bound portfolio, consisting of 88 pages, about 11x14, printed on heavy plate paper, and containing 43 designs with floor plans, of practical, tasteful, and comfortable country homes, ranging in cost from $1,000 to $5,000 complete. The designs have been carefully selected, as embodying the best efforts of various architects throughout the country. Every one of the houses has already been built, and all of the illustrations are half-tone engravings, made direct from photographs of the completed structures, taken specially by the *Scientific American* artists. In many cases, two perspective views of the same house are shown. Several illustrations of inexpensive stables are also included among the designs.

The location of the dwellings, the cost, owners' and architects' names and addresses, are given, together with a description of the dwelling, thus enabling, if desired, a personal inspection of the dwelling or direct correspondence with the architect or owner.

Architects, builders, and those intending to build will find many new and valuable suggestions among the up-to-date designs illustrated in this handsome portfolio. Price, $2.00 by mail, postpaid. Munn & Co., publishers of the *Scientific American*, 361 Broadway, New York.

SEMI-ANNUAL SUMMARY OF BUILDING OPERATIONS.

IN the following table we present the number and value of buildings erected in San Francisco during the first six months, it will be noticed there is a decrease in both the number of buildings and the amount of cost as compared with the first six months of last year.

FOR FIRST SIX MONTHS.—1897.

1897	No. of Building	No. of Contracts	Brick Building Value	No. of Building	No. of Contracts	Frame Building Value.	No. of Buildings	No. of Contract	Alterations & Additions Value.	No. of Buildings	No. of Contracts	Total Value.
Jan'ry....	12	16	$ 128,040	22	24	$ 53,524	3	3	$ 7,917	37	45	$ 190,081
Feb'ry....	6	17	181,128	21	24	71,475	8	8	28,028	35	49	280,631
March....	10	18	253,122	44	47	135,619	10	10	17,234	64	75	405,975
April.....	6	22	154,782	71	75	227,370	25	25	100,780	102	122	472,932
May.....	13	19	116,956	40	43	147,385	11	11	13,086	64	73	277,427
June.....	7	9	48,718	45	48	102,750	19	20	49,994	71	77	201,462
Total	54	101	$ 888,926	243	263	$ 788,123	76	77	$217,039	373	441	$1,888,488

To this amount has been added the further estimated sum of $500,000 where costs have not been given, which would make the total for the first six months, $2,388,488.

FOR FIRST SIX MONTHS.—1896.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

When Defects of Construction are not Waived.—A defect in work done on a public building is not waived, where the commissioner of public works takes possession of it from necessity, but expressly states that this is done without prejudice to any rights against the contractor, and refuses to give a certificate that the work is satisfactory.

MacKnight Flintic Stone Co. v. N. Y. City, 43 N. Y. Supp. Rep. 139.

What is Not a Water-Tight Cellar.—A contract to make a cellar "water-tight" is not carried out, where after the work is done water leaks into such cellar; although the contractor puts under the floor an automatic instrument, which while at work keeps the cellar dry.

MacKnight Flintic Stone Co. v. N. Y. City, 45 N. Y. Supp, 139.

Liability of Owner for Delays of Architect.—If the architect employed by the owner to superintend the erection of a building, who is to direct the work, and is by the contract made the arbiter of its proper performance, delays the contractor unreasonably in his work for the benefit of the owner and other contractors, and by allowing such other contractors to obstruct the work, renders it necessary for the contractor to do his part in an unusual manner, which adds largely to the cost, the owner is liable to such contractor for the loss resulting.

Genovese v. Third Ave. R. Co., 43 N. Y. Supp. Rep. 8.

When Injunction will not Lie Against Owner.—That a subcontractor is proceeding with work in a negligent and improper manner, to the injury of adjoining property, affords no ground for a preliminary injunction against the owner, who has no control over the manner in which the work is being done.

Hill v. Schneider, 43 N. Y. Supp. Reporter, 1.

Contract and Plans must be Filed in California.—A contract to erect a house in conformity with plans prepared by and in possession of a designated architect, filed with the recorder without a copy of the plans, does not comply with the law of California (Sec. 1183) which requires building contracts to be in writing, and to be filed before work is commenced.

Pierce v. Birkhold, Cal., 47 Pacific Reporter, 681.

Owner Liable for Delays of Architect.—A provision in a building contract by which the architect is given authority to adjust and make allowance to the contractor for loss of time due to delays caused by other contractors does not preclude a recovery by the contractor against the owner for delays and obstructions caused by the acts of the architect as superintendent for the owner.

Genovese v. Third Ave. R. Co., 34 N. Y. Supp. Rep. 8.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street,

Seth Babson, Pres. W. P. Moore, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Theo. A. Eisen, Pres. Arthur B. Benton, Vice-Pres.
William C. Aiken, Sec'y. August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

Jos. C. Hornblower, Pres. Jas. G. Hill, Vice-Pres.
E. W. Dunn, Jr., Sec. W. J. Marsh, Treas.

Association of Architects of Arizona, meetings held at Phoenix, Arizona.

D. W. Millard, Pres. T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

E. J. Molera, Pres. W. F. C. Hasson, Vice-Pres.
Otto Von Geldern, Sec. Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

Oscar Lewis, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. M. V. Brady, Sec.

HOW THE TUNNEL WAS MADE.

IN CONSTRUCTING the Blackwall tunnel the first difficulties the engineers had to face were the dimensions, which, owing to the amount of traffic the tunnel would have to provide for, were of a size unheard of before in the history of subaqueous tunnels. The largest tunnel of the kind ever constructed prior to the Blackwall was the St. Clair River tunnel, in America, having a diameter of about 20 feet, the Blackwall being 27 feet, says *Lloyd's London Weekly*. This diameter was proposed by Mr. Alexander R. Binnie, the chief engineer of the L. C. C., in order to accommodate both

vehicular and passenger traffic, and by the engineering fraternity generally it was looked upon as a size impossible of accomplishment. Mr. Bennie, in his article in *London* on the planning and construction of the tunnel, says:—"It was frankly held to be an impossible proposal by some of the leaders in the engineering profession. One of the older members—a gentleman of great experience—impressed upon me the fact that failure would mean the loss of all professional reputation, and even the late Mr. Greathead, as an old and kind friend, warned me not to be too sanguine of success." But Mr. Binnie was confident of success—a confidence which he has magnificently justified; all opposition was overcome; and his proposal adopted. The contractors, Messrs. S. Pearson and Son, were the next to be warned of the impossibility of the task they were undertaking, and we are told in *London* that "an engineer of the foremost rank, with an experience greater than that of any other engineer in difficult subaqueous tunnelling, deemed it his duty, from the regard he had for Messrs. Pearson, to advise them not to risk their fortune and reputation in undertaking a task that was impossible of fulfillment." They, however, like Mr. Binnie, had confidence in their own judgment, and like him have also been magnificently justified.

The tunnel is 6,200 feet in length, and of this 1,220 feet is under the bed of the Thames, and the commencement of the work early in 1892 was the making of the approaches on both sides of the river. These approaches had naturally to be of considerable length, so that heavy traffic might not be rendered difficult by steepness of incline, and the gradients nowhere exceed that of the Haymarket. The approaches were commenced on what is technically termed the "cut and cover" system—an excavation, somewhat resembling a railway cutting, being worked out and bricked as it proceeded, but long before the actual river was reached tunnelling was begun, and here the principal instrument in the work came into operation. This was the great cutting-shield, the largest of its kind ever seen. It was suggested by Sir Benjamin Baker, as an improved form of the implement designed by Brunel for cutting the Thames tunnel, but the special and distinguishing features were designed especially for boring the Blackwall tunnel by Mr. E. W. Moir, Messrs. Pearsons' engineer and manager. The total length of this shield is 19 feet 6 inches, and the outside shell consists of four five-eights of an inch steel plates. Air tight diaphragms divide it into two parts, so that a great air pressure could be kept at the working face of the shield, which has four rooms and contains twelve working compartments. The cutting portion of this gigantic implement consists simply of the outer shell referred to fixed by circular girders to an inner skin, the two joining to form a cutting outside edge. This was driven forward by twenty-eight hydraulic rams, the pressure as a rule being 2¾ tons to the square inch. Every time the shield was puthed forward it made room for an iron ring composed of fourteen segments, each weighing a ton, the segments being placed in position by hydraulic elevators attached to the rear of the shield. These rings form the outer lining of the tunnel, being connected with each other by seventy bolts, and no fewer than 17,000 segments have been used in the construction of the great work. Cement concrete faced with white glazed tiles lines the iron skin, and gives the tunnel the bright appearance it now presents.

Another prominent feature in the construction of the tunnel was the use of compressed air in the workings. This driven into the tunnel by engines of 1200 horse power by its pressure against the face of the river bed, as the shield cut it, prevented any inrush of water. An ingenious arrangement called an "air lock" shut off the finished portion of the tunnel from that in progress of construction, preventing the escape of the compressed air yet allowing for a passage from the ordinary atmosphere to the condensed one, on much the same principle that a canal lock allows boats access to or from divisions of water at varying levels. The lock resembled nothing so much as a large iron boiler embedded in a concrete block that hermetically sealed one end of the tunnel. At either end of the boiler were doors, each opening inwards towards the compressed air side. In this boiler a person passing from the ordinary atmosphere to the working one would sit down, a pipe would be opened, and the compressed air rushed in with a roar until the pressure in the lock was equal with that in the workings, when the further door could be opened, and the part of the tunnel in progress entered. The sensation of the person in the thicker atmosphere was merely that of an increased weight and somewhat heavier breathing. It was in the lock during the equalization of the atmospheres that any unpleasantness, singing in the head, popping in the ears, pain across the forehead, and such-like was felt. At least this was the experience of our representative when he visited the tunnel at the time it was bored about half way across the river. A description was given in *Lloyd's* in two illustrated articles in May, 1895. The scene in the workings was weird and striking in the highest degree. Down the middle of the tunnel ran a tramway, bearing trucks that carried the clay or gravel cut out from the face by the men in the shield. Gangs of men moved silently under the electric light, which was used throughout, some fixing cement, others riveting, others "grouting," as the process is called, by which an outer coating of concrete is given to each ring as it is fixed. So, day and night, the work went steadily on, only a small line of foam on the river marking the position of the shield to persons above ground. Some days only a few inches could be made, and on others several feet, but bit by bit it advanced until the two great "caissons," as the shafts on either side the river are called, were connected by this latest London roadway. Never was so great a work carried out with so few accidents, thanks to the ever-careful supervision of the resident engineers Messrs. Hay and Fitzmaurice. Once the cutting edge of the shield was turned by an encounter with a great piece of lime-stone rock, and the implement was only repaired after considerable delay and at a cost of between 7,000*l* and 10,000*l*. This however, was the only great mishap encountered, and the work so many practical men pronounced impossible has been brought to a triumphant issue. In the making of the tunnel a million tiles have been used and seven million bricks, which figures convey but a faint idea of the vastness of the undertaking; and its need and utility in uniting two great districts are made plain by the following fact:—The contractors had occasion to move a large crane from one side of the river to the other. Across the Themes it was about half a mile, but in order to get around it had to be drawn by way of Tower-bridge, miles above, so that the journey was a matter of some ten miles.—[Since the tunnel has bee opened a loud echo has come ito being and it is said the uproar is deafening as vehicles proceed through its spaces.—Ed.]

STONE PRINCIPALS AND INTERNAL ARCHES.

AVERY rare mode of constructing roofs is that in which stone principals occur instead of timber. The examples in England are few, and one or two are mentioned in the "Architectural Dictionary." The south transept of Minchin Hampton Church, Gloucestershire, has a pair of stone principals, and at Willingham, Cambridgeshire, a smaller instance may be seen. At Carlow a stone principal is constructed in the shape of a trefoiled arch within an acutely pointed arch, the object of which form is apparently to obviate the necessity of counterforts on the outside, though the writer does not give details. The weight of stone concentrated at the "cusps" of the trefoil arch were no doubt intended to act as counterbalancing forces, their centres of gravity falling within the walls. Stone ribs supporting the purlins of roofs are common in many churches, and their object was doubtless to save trouble. Whatever motive induced the old architects to use them, it is quite certain these principals add to the monumental character of a building. The stone arching connects, in a pleasing manner, the two opposite walls, and the roof becomes a more integral part of the structure than it does when timber is employed. But the construction requires considerable care, and the centring should not be "struck" till the work has had good time to settle. If the walls are thick and low, the springing of the ribs may be made to commence low down, and the side walls do not require any buttresses, and it is a common and very effective manner of roofing porches, small chapels, etc. In lofty structures the employment of stone principals is more doubtful, for unless there is ample masonry provided in the form, either in internal piers or extended buttresses, observed in some of the churches in the South of France, great risk is run, as there are not a few examples to witness in spreading naves and fractured arches. In this connection we may point architects to tower and chancel arches, many of which, both in old and modern churches, bear evidence of the "sleepless" activity of the arch, when improperly tampered with or not duly buttressed. Many an old Norman and obtuse-pointed Transitional arch to be seen in the village churches in the south and west of England, show signs of the weakness and instability of the abutments. In probably more than half the cases to be met with, the fault lies with the tampering spirit of later times in making external vaults for interment, or in injudiciously performed alterations—as for instance, the enlargement of a church by the addition of transepts. During the progress of these alterations, the wall is cut through and weakened, no shores are erected to help the abutments, which have been so recklessly deprived of their bond with the adjacent walling, or the excavations for the foundations of new work are made in dangerous proximity to old buttresses or footings. In new churches we have seen chancel arches cracked, and serious signs of instability in the masonry of the walls; it is not unfrequently the practice in these days of partial building, to afford a temporary support to the chancel arch before the aisles are added by the erection of a rough brick flying buttress on the outside; but, it is needless to say, very much more caution is required than is sometimes taken. In one case we know, where this expedient was adopted, the result has proved so bad that the arch will doubtless require to be rebuilt sooner or later. The chief point, of course, is to make such a buttress the permanent one, so that it will not require to be tampered with when the additions are made; and to secure safety the centring should be very carefully "struck," and not until the work has been quite finished, and the mortar set. Architects might very well take a lesson here from their brother professionals the engineers, although the latter cannot be said to be always infallible in their arch construction. A pleasing proportion of an interior arched opening is one in which the eye naturally takes immediate cognizance of the proportion between it and the solid masonry of the abutments, and discerns nothing to offend it. In very many of our new churches, the mass of masonry above the arch-crown often reserved for mosaic or colour decoration is disproportionately large to the abutments, or the span looks exceedingly wide for the buttresses, and whenever we meet with such an instance, the suggest of a counterfort sufficient and necessary to satisfy visual requirements and set the mind at rest is important. The question is one which concerns good proportion as much as mechanical stability; and, in fact, if the eye were consulted and followed in this and similar matters more loyally than it is, we should have better and more carefully designed buildings—appealing to our sense of just balance of parts and artistic fitness.—*The Building News.*

BUSINESS MOSAICS.

George Goodman, Patentee and Manufacturer of artificial stone, is one of the gentlemen who consumes an immense amount of Portland Cement. The result may be seen in many parts of the city, in the good sidewalks, garden warks, as well as foundations and bulkheads. Mr. Goodman does his work well and therefore gets lots of it to do; he can be found at 307 Montgomery street.

L. E. Clawson & Co., 1340 Market street, San Francisco, furnish everything in the line of Patent Chimneys that comply with the new fire ordinance. An illustrated circular sent on application.

Ives Patent Sash Locks are now finished in cold rolled steel, bronze and brass in all the popular finishes. Hobart B. Ives & Co., New Haven, Conn.

Cabot's Creosote Shingle Stains are manufactured by Samuel Cabot, Boston, Mass., can be obtained of Mr. Charles J. Waterhouse, agent, 35 New Montgomery street, San Francisco. The merits of this stain are well known among architects as a protection to wood; it is unequaled—entirely preventing the blackening of redwood. Samples and prices on application to the above address.

The Norton Door Check and Spring with its simple and durable air cushion check, is exactly what you want to prevent the slamming of your door; as this is not liable to get out of order, and duplicate parts can always be obtained if it does—be wise in time and provide yourself with one, thus stopping the slamming of the door.

To those in favor of home industry we suggest the patronizing of P. & B. building paper, manufactnred by the Paraffine Paint Co.; everything supplied by this reliable firm can be depended upon as represented, and home made at that—116 Battery street, San Francisco.

Facts about paint is what we all want who intend painting—therefore go to the fountain head and get W. P. Fuller & Co., to tell you something in this line. They recommend Phoenix Pure Paint because it is made from pure material only and is finely and thoroughly ground and mixed with heavy machinery.

Joseph Budde can be found at his old stand, 575 Mission street, San Francisco. Mr. Budde makes his mark as a manufacturer of sanitary appliances in the plumbing line, and thus you are able to partonize home industry and get what you want in that line at the same time. Mr. Budde has been in the business so many years, is know so favorably to the trade that it is hardly necessary to call attention to his advertisement on page vii of this journal.

Parties desiring to purchase cement should go to W. R. Grace & Co., 203 California street, and get the celebrated Josson brand.

The Pacific American Decorating Company, manufacturers of stained and art glass—offer you the opportunity of having your house decorated with landscapes, marine views or photographs of persons and animals, 26 O'Farrell street, room 3.

CITY BUILDING NEWS.

o near Hoffman. Cottage; owner, John Galloway; cost $1600.

Baker near Greenwich. Two-story frame; owner, J. A. Voegnison; architect, E. Depierre; contractor, A. Dahlberg; signed, June 19; filed, June 21; cost $2725.

Belvedere near Fredrick. Two-story frame; owner, Mrs. M. J. Goodwin; contractor, E. W. Hyde; signed, June 25; filed, June 28; cost $3100.

Beulah near Stanyan. Two-story frame; owner, Henry W. Copp; contractor, John Steirlien; signed, April 30; filed, July 7; cost $4100.

Boardman Place near Bryant. Frame building; owner, Giovanni Camiera; architect, P. De Martini; contractors, Martini & Pagano; signed, June 15; filed, June 21; cost $2550.

Bryant near 3rd. Three-story frame; owner, Alice Colleton, architect, P. J. Lynch; contractor, P. J. Scott; signed, June 21; filed, June 24; cost $3034.

Broadway near Devisadero. Two-story frame; owner, Thomas Magee, Jr.; architects, Percy & Hamilton; signed, June 28; filed, June 30; cost $3800.

Bush near Montgomery. Alterations to the old Standard Theatre; days work; cost $5000.

California and St. Mary's Place. Alterations and additions; owners, Grasso & Co.; architect, W. H. Lillie; contractor, John Miron; signed, July 6; filed, July 7; cost $1300.

Green near Jones. To build; owner, Fred Marriot; architects, Laver & Mullany; contractor, Jno. Blake; cost $800.

Olay near Larkin. Alterations and additions; owner, A. G. Burgner; architect, G. A. Bordwell; contractor, M. J. Logan; signed, June 25; filed, June 25; cost $2275.

Clay Ave. near Clay. Two-story brick school house; owner, John F. English; architects, Havens & Toepke; contractor, J. G. Adams; signed, June 30; filed, July 7; cost $2170.

Clay near Larkin. Alterations and additions; owner, Harriett L. Van Bibber; architect, W. H. Wharff; contractor, A. L. Whitney; signed, July 13; filed, July 13; cost $2278.

Clara near 4th. Alterations and additions; owner, Wallace A. Wise; architect, R. H. White; contractor, A. J. Anderson; signed, July 28; filed, July 3; cost $1580.

Devisadero near Union. To build; owner, Sarah Anderson; architect, T. D. Newsom; contractor, J. H. Simpson; signed, June 14; filed, June 16; cost $2150.

Douglass and 17th. Two-story frame; owner, C. Ruhland; builder, C. Zwierlein; cost $3600.

Ellis near Mason. Concrete foundation for six-story brick; owner, L. H. Sly; contractors, Gray Bros; signed, June 18; filed, June 19; cost $2790.

Ellis near Steiner. Two-story frame; owner, Hugo Klenin; architect, W. H. Armitage; contractors, Garson & Otter; signed, July 1; filed, July 6; cost $2635.

Ellis street, No. 621-631. Alterations and additions; owner, Dr. P. H. Flood; architect, James E. Wolfe; contractor, F. A. Blanchard; signed, July 7; filed, July 7; cost $1570.

Ellis near Mason. Six-story brick; owner, L. H. Sly; days work; cost $60,000.

Ellis and Anna Lane. Carpenter work etc., for six-story brick; owner, W. J. Somers; architects, Percy & Hamilton; contractor, T. M. McLachlan; signed, June 25; filed, July 12; cost $13,040.

Ellis and Mason. Underpinning Langham hotel; contractor, M. Kelleher; cost $1000.

Eighteenth near Church. Cottage; owner, H. E. Brown; contractor, C. W. Duffie; signed, July 8; filed, July 9; cost $1835.

Fell and Masonic Ave. Three-story frame; owner, Martin A. Aronsohn; architect, R. H. White; contractor, Donald Currie; signed, June 8; filed, June 16; cost $5300.

Fell near Scott. Three-story frame; owner, R. Nichols; architect, C. W. Duffie; contractor, S. A. Brown; signed, June 21; filed, June 25; cost $3894.

Fell near Cole. Carpenter work; owner, Martin Kealing; architects, Cahill & Condon; contractor, Bernard Dryer; signed. June 28; filed, July 7; cost $6350.

Folsom and Alice. Alterations and additions; owner, F. J. Hund; architect, C. A. Meusdorffer; contractor, Issac Penny; signed, June 24; filed, June 25; cost $2575.

Folsom near 4th. Two-story brick; owners, Schroth & Westerfield; superintendent, G. T. Watson; contractor, Wm. Little; signed, June 25; filed, June 28; cost $14,350.

Folsom and Harriett. Three-story frame; owner, Harry Bush; contractor, C. M. Depew; cost $5000.

Fourteenth Ave. near M. street. Cottage; owner, Edward Eggers; contractor, M. J. Scott; signed, June 23; filed, June 23; cost $1240.

Franklin and Hickory Ave. Three-story frame; owner, Frank A. Meyer; contractor, R. O. Chandler; signed, July 8; filed, July 8; cost $5200.

Geary and Powell. Additions and alterations; owner, Mrs. Charlotte F. Clarke; architect, P. Schwerdt; contractor, Val Franz; signed, July 10; filed, July 12; cost $11,700

Geary and Stockton. Cast iron fences; owner, Spring Valley Water Works; architect, Clinton Day; contractor, H. Haustein; signed, June 22; filed, July 9; cost $6657.

Geary and Powell. Plumbing work; owner, Mrs. Charlott F. Clarke; architect, F. Schwerdt; contractor, Val Franz; sub-contractor, H. Williamson; signed, July 12; filed, July 14; cost $1350. Brick and granite work; contractor, D. J. Brannan; signed, July 12; filed, July 14; cost $2575.

Golden Court near Sacramento. Repairs; owners, Ellen and John Golden; superintendent, Lawrance Kelly; contractor, J. M. Harcourt; signed, July July 13; filed, July 13; cost not given.

Gough near Sacramento. To build; owner, Robert C. Foutet; architects, Coxhead & Coxhead; contractor, Chas. M. Depew; signed, July 3; filed, July 7; cost $5340.

Haight near Scott. Two-story frame; owner, J. D. Feldmann; architect, Emil John; contractor, C. Kreeker; signed, June 14; filed, June 15; cost $4000.

Haight and Shrader. Two-story frame; owner, I. Steinhart; architect, W. H. Lillie; contractor, M. J. Savage; signed, June 30; filed, July 6; cost $5594.

Harrison near 4th. Three-story frame; owner, John J. Sweeney; architect, Oliver Everett; contractors, Barrett & Leahy; signed, July 7; filed, July 8; cost $5733.

Henry near Castro. Two-story frame; owner, Miss Ann Hall; contractor, Charles Koenig; signed, June 17; filed, June 19; cost $1448.

Hill near Noe. One-story frame; owner, L. A. Smith; contractor, D. Einstein; signed, June 28; filed, July 10 cost $1150.

Jones near Washington. Two-story frame; owner, Henry L. Wagner; architect, Albert L. Fair; contractor, Wm. Knowles; signed, June 14; filed, June 15; cost $8538.

Joost Ave. Frame building; owner, Mrs. Hicks; cost $1200.

Joost Ave. Frame dwelling; owner, Mr. Stammer; cost $1200.

Iowa near Yolo. One-story frame; owners, Thomas and Ellen Commors; architect, M. G. Bughee; contractors, Brennan & Nichols; signed, June 21; filed, July 8; cost $1400.

Larkin near Sacramento. To build; owner, W. J. Harris; builder, C. Zwierlein; cost $8000.

Lily Ave. near Buchanan. Alterations and additions; owner, Margaret Corbett; architect, A. Hildebrand; contractors, Klein & Eickholt; signed, July 8; filed, July 9; cost $1530.

Lundy's Lane near Esmeralda Ave. Cottage; owner, R. Sample; architect, G. H. Batcheider; contractor, W. W. Elliott; signed, June 22; filed, June 24; cost $1000.

Lundy's Lane near Esmeralda. Cottage; owner, R. Sample; contractor, W. W. Elliott; cost $1000.

Market near 5th. Alteration to Pythian Castle Building; architects, Pissis & Moore; contractor, W. A. Lange; cost $1000.

Market and 3rd. Models and carving in sand stone; owner, Claus Spreckels; architects, Reid Bros; contractor, Rupert Schmid; signed, June 12; filed, July 7; cost $1350.

McAllister near Lyon. To build; owner, Eurico G. Bressi; architects, W. Mooser & Son; contractor, A. Stevens; signed, June 19; filed, June 26; cost $2889.

Minnesota near 22d. Alterations and additions; owners, Thomas Brown & Alice Brown; contractor, Frank Coyer; signed, June 11; filed, June 16; cost $1625.

Mission near 18th. One-story brick; owner, Pacific Telegraph and Telephone Co.; contractor, J. A. Wilson; signed, July 1; filed, July 3; cost $4100.

Montgomery and Sutter. Three-story brick; owner, Anna L. Whittell; architect, Townsend & Wyneken; contractors, Veitch & Bros.; signed, June 17; filed, June 12; cost $21689.

Oak and Ashbury. Two-story frame; owner, Geo. F. Gorden; architect, G. A. Behrend; contractor, H. Brown; signed, July 6; filed, July 6; cost $3478.

O'Farrell near Laguna. Alterations and additions; owner, Moses Samuels; architect, A. F. Oakey; contractor, H. Jacks; signed, June 15; filed, June 17; cost $1552.

O'Farrell near Gough. Two-story frame; owner, James Tierney; architect, T. J. Welsh; signed, June 24; filed, June 28; cost $5545.

O'Farrell near Gough. Plumbing, etc.; owner, Jas. Tierney; architect, T. J. Welsh; contractor, W. F. Wilson; cost $883. Painting; contractor, L. J. Dwyer; cost $599. Tinning, etc.; contractors, Conlin & Roberts; cost $274.

Pacific Ave. near Octavia. Plumbing, etc; owner, E. J. McCutchen; architect, E. A. Mathews; contractors, Ickelheimer & Bros; signed, June 15; filed, June 16; cost $1444.

Pacific Ave and Webster. To build; owner, Mrs. James A. Robinson; architect, F. S. Van Frees; contractors, Anderson & Greig; signed, June 11; filed, June 19; cost $5472.

Post and Taylor. Three-story frame; owner, Estate of H. Molleshaner; architect, T. J. Welsh; contractor, J. E. Mooney; signed, June 14; filed, June 22; cost $7700. Plumbing, etc; contractor, Jas. McAllister; signed, June 21; filed, June 22; cost $1275.

Post near Laguna. To build; owner, Chas. H. Gottschalk; architect, Wm. Curlett; contractor, Wm. Linden; signed, June 29; filed, June 30; cost $3835.

Post near Laguna. Three-story frame; owner, Mrs. Wolf; contractors, Phillips & Hood; cost $6000.

Powell near Geary. Brick, carpentry work, etc; owner, Mrs. Margaret A. Skelly; architect, P. Schwerdt; contractor, D. Powers; signed, July 12; filed, July 14; cost $5557.

Powell near Bush. Four-story frame; owner, Julia Hyde; architects, Shea & Shea; contractor, L. W. Coburn; signed, June 17; filed, June 26; cost $4800.

Pine near Polk. Grading, carpentry, iron, etc; owner, E. F. Guedet; architect, cost $5177. Painting, etc; contractor, C. E. Schwartz; signed, July 10; filed, July 12; cost $460. Plumbing, etc; contractors, Schnaz & Grady; signed, July 10; filed, July 12; cost $662.

Sanchez near Alvarado. Cottage; owner, Mrs. Emma Landgrebe; contractors, Carl Schley & C. A. Doss; signed, June 23; filed, June 25; cost $1180.

San Bruno Road near Gates street. One-story frame; owner, Mrs. Elizabeth Taylor; builder C. Zwierlein; cost $1000.

Seventh Ave. near M. Cottage; owner, Nathaniel Hallinan; architect, M. J. Welsh; contractor, J. B. Quinn; signed, June 15; filed, June 16; cost $1300.

Stanley Place near Bryant. Alterations and additiods; owner, Fannie Gluckmay; contractor, R. C. Stiller; signed, June 24; filed, June 24; cost $1067.

Steiner near Broadway. To build; owner, C. R. Havens; architects, Hermann & Swain; contractor, G. Peterson; signed, June 23; filed, June 23; cost $4240.

Stevenson near 3rd. Excavation for brick building; owner, Claus Spreckels; architects, Reid Bros; contractor, J. Tuttle; signed, June 10; filed, June 26; cost $1290.

Sixteenth street. One-story frame; owner, J. H. Burns; days work; cost $1500.

Stockton and Geary. Elevator; owner Spring Valley Water Works; architect, Clinton Day; contractors, Cahill & Hall Elevator Co; signed, July 2; filed, July 2; cost $14,870.

Taylor and Bernard. Additions and alterations; owner, Catherine Fahey; architect, H. D. Mitchell; contractor, Peter Hamilton; signed, June 16; filed, June 18; cost $1200.

Tehama near 2d. To build; owner, John Driscoll; architects, Rowell & Collins; contractor, David R. Perry; signed, July 9; filed, July 10; cost $2300.

Twelfth near Harrison. Alterations and additions; owner, Mrs; L. M. Schmidt; architect, W. H. Wharff; contractors, Enquest & Wright; signed, June 14; filed, June 15; cost $1125.

Twelfth Ave. near A. street. Cottage; owners, Geo. E. Mitchell and Mary Ann Mitchell; contractors, A. P. Ely & J. W. Smith; signed, June 14; filed, June 16; cost $1102.

Twelfth Ave. near A. Cottage; owner, Francis Miller; contractor, L. G. Bergren; signed, July 6; filed, July 8; cost $1180.

Twenty-third near Hoffman. Cottage; owner, F. W. Westfall; cost $1600.

Twenty-third near Hoffman. Cottage; owner, J. Wilhmson; cost $1600.

Twenty-third near Noe. To build; owner, Sarah Nesbitt; contractor, J. O. Dyar; signed, July 6; filed, July 8; cost $2600.

Twenty-seventh and Church. To build; owners, Thomas and Catherine Fanning; contractor, V. G. Godin; signed, June 21; filed, June 22; cost $2450.

Vallejo near Powell. To build; owner, Issac Fox; architect, A. W. Marquis; contractor, D. A. McIntosh; signed, June 16; filed, June 18; cost $1325.

Vermont near Yolo. To build; owner, Mrs. Kelleher; builder, C. Zwierlein; cost $1200.

Washington near Van Ness. Alterations and additions; owner, Mrs. Margaret J. Jones; architects, Coxhead & Coxhead; contractor, M. C. Lynch; signed, June 16; filed, June 21; cost $4831.50.

Washington and Spruce. To build; owner, Ed. G. Carrero; architect, T. P. Ross; contractor, Fred Miller; cost $3980.

Webster near California. Alterations, etc; owner, Lillian D. Reynolds; architects, Herman & Swain; contractors, Anderson & Stockholm; signed, July 2; filed, July 7; cost $1935.

The California Architect and Building News.

OFFICE, 408 CALIFORNIA STREET, SAN FRANCISCO, CAL., U. S. A.

VOLUME XVIII. AUGUST 20th, 1897. NUMBER 8.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

Published on or about the 20th of each month by The California Architectural Publishing Company. The Stockholders being Architects and others interested in the profession.

SUBSCRIPTION TO THE JOURNAL, - $3.00 PER YEAR IN ADVANCE.

ESTABLISHED 1879. INCORPORATED 1897.
NOW IN THE EIGHTEENTH YEAR.

OLIVER EVERETT Secretary.

ADVERTISING RATES:

Space	1 Month.	3 Months.	6 Months.	12 Months.
1 Inch	$ 1 50	$ 4 00	$ 7 50	$ 13 00

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

AS THE MATTER of a New Charter for San Francisco is again on the tapis the time is opportune for remarks as to the position of architects, engineers and builders in it.

In the most important place, this being the age of specialization it seems that the Architectural Department of the Municipal Government should be kept separate from the Engineering Department.

In all American Charters we believe so far no distinction has been made, and all are grouped in the Board of Public Works; who are generally supposed to be engineers.

A little consideration will show that this is very inadvisable. The distinction is very palpable between the two departments; in fact, there is nothing apparently in common between them.

One busies itself with the laying of sewers, building of roads and walks, water supply, gas and electric light supply, bridge building, street cleaning, railroads, telegraphs and telephone, subways, and the charge and care of all these things. It also would naturally include all surveying.

San Francisco being a seaport it would also include all marine engineering such as building of wharves, dockage, etc., and the charge of the same.

All this comes appropriately under the term "Works" so that "Works Department" or "Engineering Department" could be either of them used.

On the other hand the Architectural Department, or what could be called for short the "Building Department" includes all constructions for protection from the weather; and those made for the delight of the eye, such as parks, statues, monuments, gardens, museums and othor art treasures of the City.

One sees at a glance that a different order of men are required to haudle these latter works than those mentioned before—and it is hardly necessary to note that the two geniuses have been very seldom indeed united in one man—and, with the present complexity of public wants, it is im

possible for one man or set of men to do justice to both. The head of the first department should be an engineer, of the second department an architect.

The Architectural Department should have charge of the construction and repair of all public buildings, the lighting and all other installations in connection with said buildings and the furniture within the same.

One bureau of the department should be empowered to make a proper building ordinance including plumbing regulations and see it enforced by Building Inspectors—who would take the place of the present Fire Wardens and Health Inspectors. In regard to the designs of public buildings and monuments, fountains, parks, etc., which more particularly interest the architect—the example of our National Government in the matter is a good one. All constructions of this character costing complete over $50,000, should have designs open to competition.

The City parks would naturally come under the Landscape Architectural Bureau of the Department—being artistic creations—that being made the great distinction between each department; any other classification does not seem to be so satisfactory.

A few thoughts in regard to the carrying out of the work of these two departments may be apropos. The public service has always a large attraction for the citizens, due no doubt to a feeling on his part that he is partly working for himself when working for the city, being a constituent of the body politic—while, when working for a private employer he feels that the profit of none of his work comes back to himself.

So as to allow as many as possible to participate in the fruition of this laudable desire, the hours of the City should never exceed seven hours, and be less whenever the people are educated to the idea. Two ends are gained by this more people are employed and by allowing only seven hours pay, it prevents those who may have private work from rushing into government situations.

Again all the labor required in these departments should be done by the City by day's work and contracts should be tabooed. There is an element of speculation (gambling in English) about a lowest bid contract which is demoralizing; if the work is large, only rich contractors can bid, and the number being small the temptation to pool their issues is great, and the City has to pay more than the work is worth; or, if it be small enough to encourage a large number of bidders, the lowest bidders generally loses; as we find in quite a quantity of national work let out on this system. In the latter case the City gets something for nothing which every honest citizen abhors.

PUBLIC UTILITIES IN SAN FRANCISCO.

CITY GOVERNMENT A NATIONAL QUESTION.

THE problem of municipal government has become one of the highest concern to the entire nation. It is, in truth, a question whose solution affects the interest of all the people. At present one-third of the people of the United States dwell in cities. One-tenth of the entire population of the Republic live in the four great cities of New York, Philadelphia, Boston and Chicago. American cities resemble each other so closely, that the experience of one will generally serve as a lesson for all.

OUR CITY HAS NO PUBLIC DEBT.

In the first place, the early settlers of San Francisco, expecting to return soon to their Eastern homes, were unwilling to discount an uncertain future. They had not in view the requirements of a metropolis of 350,000 people. Therefore, no provision for any public indebtedness was provided; and we have to-day a municipality without bonds. One hundred and sixty miles of paved streets have been constructed, costly public buildings have been erected; a magnificent public park, costing annually a quarter of a million dollars; and yet San Francisco is practically out of debt. No other large city on earth can match this remarkable record.

OUR CITY OWNS NO UTILITIES.

In the second place, San Francisco possesses no public utilities. Other large cities have issued bonds mainly to acquire municipal ownership of the great necessities of the people. San Francisco has done neither. The public property of the city, amounting to $25,000,000, has been either inherited or paid for by current taxation. Nearly all progressive modern cities own and often operate some public utilities. San Francisco has allowed great tax-levying corporations to perform these municipal functions.

VALUABLE FRANCHISES GIVEN AWAY.

Our city has given away for long periods, without compensation or reservation, valuable franchises for street railways, telegraph, telephone, subways, water supply, and gas and electric lighting. Laws governing the sale of franchises have only been enacted within recent years. To recover her lost advantages, San Francisco must now wait until the existing privileges expire by limitation. The present Constitution of California, however, has broken the monopoly of water and light franchises by allowing any person to use the streets for such purposes under reasonable conditions.

MONOPOLY A LOGICAL RESULT.

The natural result of the existence of these gigantic corporations has been powerful monopolies and the imposition of excessive rates for all kinds of service. Morally worse than this has been the resulting suspicion of the curruption of public bodies. Public servants in the Legislature, in the council, and even in the judiciary are exposed to the debasing machinations of these unscrupulous corporations. They have debauched politics and have established an "imperium in imperio," subversive almost of the State government itself.

PUBLIC OWNERSHIP A NECESSITY.

These indisputable facts emphasize more lucidly than any argument the necessity of the public ownership of utilities. With a reform in the civil service, better results could certainly be attained. Moreover, public bodies would not be exposed to the insidious inroads of corruption, carrying with it the ultimate destruction of representative government.

PRIVATE OWNERSHIP INCLUDES TAXATION.

Every rise in the price of water or light is equivalent to an additional tax imposed upon the people. Every divident paid upon watered stock of transportation and other companies using public streets is an unjust and unwarranted imposition upon the people. The public streets belong to the municipality and these corporations cannot exist without their use. The first consideration of lawmakers should be the interest of all the people. Therefore, only reasonable interest should be permitted to be earned upon the actual capital invested. The $2,500,000 contributed annually by the citizens of San Francisco for the universal necessity of water and artificial light is certainly as much taxation as the very taxes levied for the support of the city government. If the people are charged double the value of these necessities, they are unjustly taxed.

ACTUAL COST THE TRUE MEASURE OF VALUE.

Reasonable interest should be estimated upon actual cost and not upon any inflated values. For example, a system of street railway has issued stock for $18,750,000 and has outstanding bonds for $11,000,000. It collects over $3,250,000 annually in fares and thus pays full interest upon all its stock and bonds. Its earning capacity with five-cent fare should, therefore, not be considered the measure of its value. Reasonable dividends could be paid upon its actual value and yet cheaper service rendered, especially during certain hours of the day. A gas company with a plant worth $5,000,000 is paying 6 per cent dividends on $10,000,000; and a water company is paying regular rates of interest on a stock and bond capitalization of $23,000,000. The citizens of San Francisco are paying $7,000,000 annually for water, artificial light and street car transportation, a sum $3,000,000 more than was raised last year by direct taxation for the support of the municipal government.

PUBLIC OWNERSHIP THE BEST SOLUTION.

The ultimate solution of this disturbing problem is municipal ownership and operation of public utilities. Modern American cities, careful to perserve representative institutions in their purity, should be prepared for this public duty. The mere power of regulation has failed to prove an adequate remedy. In practice it is the opportunity of the corrupt and the corruptor. Corporations have their duties as well as their rights.

CAPITALIZATION IS NOT FICTITIOUS.

The apparent inflated capitalization of these gigantic corporations is in reality not fictitious. It actually exists and consists of two distinct parts: first, the indispensable portion contributed by the city, and, second, the part contributed by the corporation. The latter is its actual cost to the corporation and is the basis upon which alone it should be paid.

RISK OF OWNING PUBLIC UTILITIES.

Corporations engaged in handling public utilities incur no unusual risk. They are not, in the first place, obliged to go into that business, nor would the city seriously suffer without their aid. The ownership of all property is attended with risk. Aside from the continual vicissitudes of business, private property is open to competition and may even be condemned for public use. The very magnitude of these corporations excludes ordinary competition. Furthermore, a reasonable interest upon their investments is guaranteed to them by judicial decree.

PUBLIC NECESSITIES NOT A FIELD FOR GAMBLING.

The necessities of the people are not a legitimate field for financial exploitation by private enterprise. Corporate greed should not be permitted to prey upon public bodies. The Government should see that the people are protected, not only against betrayal by their own servants, but also against invasion by corporations of their own creation.—*James D. Phelan in Merchant's Association Review.*

SUPERVISING ARCHITECT, TREASURY DEPARTMENT.

THE United States Civil Service Commission announces a competitive examination to fill the vacancy in the position of Supervising Architect of the Treasury. The salary of this position, which is one of the most important and responsible under the government, is $4500 per annum, and it is hoped that architects of high attainments and reputation may be induced by these considerations to enter the competition. It is the desire of the Department to secure a practical architect of high administrative ability to direct and supervise the work of the office force as well as the contract work done on public buildings throughout the country.

Those who enter the competition will be required to submit:

First—On blanks to be furnished by the Commission, statements relative to their training, education, and technical experience.

2—Drawing or sketch plans, specifications, and photographs or other suitable illustrations of buildings designed by them as architects or constructed under their supervision as superintendents of construction; and other information relating to such buildings of which competitors will be advised upon inquiry of the Commission.

3—(a)—A thesis relative to designing and construction, and (b) a thesis relative to office administration.

4—In addition to the forgoing tests, competitors will be required to appear on September 10, 1897, at points convenient to their place of residence where the Commission has suitable accommodations, to undergo a test in formulating a scheme for competition for a public building and in criticising designs submitted to them for their guidance and inspection.

The information called for under each of the first three heads above mentioned must be forwarded to the Commission by each competitor on or before September 10, 1897. The test under the fourth head will be given September 10, 1897. The examination papers will be rated under the direction of the Commission by a board of distinguished architects.

Those who desire to enter the competition should write at once to the United States Civil Service Commission, Washington, D. C., for application blanks and other information relating to the examination.

DOOR KNOBS.

DOOR KNOBS, in the matter of shape, have gone through quite a series of changes and improvements. The original and simplest was the one of a circular outline; next came the oval outline, which fitted the shape of the palm of the hand better; finally for sake of variety we have the egg shaped. These several shapes have been ornamented in all imaginable styles or left perfectly plain. However, notwithstanding the perfection to which shape and ornamentation has been brought, the connection between the knob and spindle, or more strictly the means of holding the knob on to the spindle, has remained the same, namely, by means of a screw tightening up the two. This primitive method has always been a source of trouble or annoyance to all concerned —to the mechanic, when he screws it up, to the householder, when he wishes to take out the lock, for about that time it is very generally the case the screwdriver cannot be found, and to the tenant when he finds the knob rattling in his hands, giving him a sensation of want of stability which is not pleasant—or finds the worn screw drop out and leave the knob loose. Everything has a good side however, and the noise of the rattling serves as a notice when the baby wants to get into the room to its mother, which no doubt is conducive to the happiness of the baby but not to the peace of the mother.

In these latter days of the century, however, here comes an invention which does away with all these troubles and annoyances. The Weatherwax Door Knob is illustrated below:

FIGURE 1.

Figure one shows the parts separately—A is the door knob and its shank—B is a small metal rod bent into the shape indicated and C is the spindle.

This is pierced with holes large enough to take the smaller leg of B—the small bent piece of metal aforesaid—these holes are ⅛" centres. At A in the shank is a small hole.

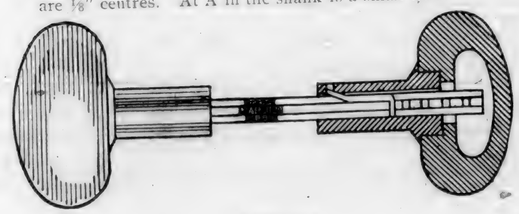

FIGURE 2.

Fig. 2, is a longitudinal section. It shows the knobs in position.

Fig. 3 shows the spindle before it is pushed into place.

The method of fitting these knobs as as follows:

After lock has been placed in position and escutcheon or roses have been screwed onto door, put the knob spindle through the door, then put the spring "B" in one of the holes in spindle; the free end of spring should just clear the escutcheon or rose when swung around. If too short move up one hole, if too long cut off with file or nippers, then put knob on spindle and press into place, when it will securely lock itself.

To remove knob insert a small awl into hole "A" and press spring down, at same time pull gently on knob.

This gives a fixture which is perfectly tight and cannot be shaken or rattled.

It can be sold for the same price as the old style which is an important item these times. It must be more durable, as there is no screw to wear out, and in appearance the lack of the screw head leaves a smooth and more sightly shank;

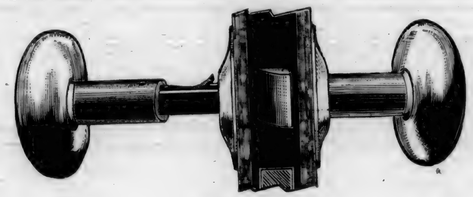

FIGURE 3.

it saves time and patience in applying or removing, and requires no tools except any awl shaped piece of wire which is found almost everywhere where knobs are.

Taking it altogether it does away with all the objections to the present system of door knobing and is in line with the present trend of everything that is labor and time saving.

The spindle and shank of these knobs are made entirely of steel instead of cast iron, the material of which all the knobs now in use are made.

PLANS FOR THE UNIVERSITY OF CALIFORNIA.

REGENT J. B. Reinstein of the University of California has returned from Europe, where he went three months ago, accompanied by H. E. Maybeck, instructor in architectural drawing, to inspect university buildings and consult with prominent architects as to the plans for the new buildings to be erected at Berkeley. The architects generally regard the opportunity presented as one of the greatest ever offered in the history of architecture, for, in addition to the beauty of the site, the large area of the grounds, and their situation on a gently rising hill overlooking the Golden Gate, Mrs. Hearst has not restricted the amount of money necessary to obtain these plans.

Mr. Reinstein stated that there will be an international concurrence of architects, together with artists, sculptors and landscape gardeners, to bring about the best results. Prof. Gaudet of Paris, who has probably had the most extensive experience of any person living in this direction, is preparing the "programme," as it is technically called. This will give in detail the requirements of the University, together with the necessary data, maps and photographs, and will be finished within a month, when copies will probably be sent to the various architects of the world.

Under the arrangements as contemplated at present the architects will be requested to send in sketches of their plans at a given date, and these will be passed upon by a jury consisting of one recognized authority each from France, Germany, England and the United States and a representative of the University, the understanding being that each architect submitting plans will receive some recompense. At least ten of the best sketches will be selected by the jury and the authors will be requested to elaborate their plans. The architects so selected will be permitted to name for additional members of the jury, and these nine jurors will select the ultimate plan. It is probable that there will be about thirty magnificent buildings in all, each of which will be built of marble or other stone. The completion of the work is not expected for many years.—*Mining and Scientific Press.*

THE MAGNETIC DIP OF ANCIENT TERRA-COTTAS.

BY THE CAVALIERE GIACOMO BONI [HON. CORR. M.].

THE DIP of a loadstone or magnetized needle was observed by George Hartmann, of Nuremberg, more than three centuries and a half ago, and was commented upon by him in a letter, dated 4th March 1544, to the Duke Albrecht of Prussia. The prototype of the modern dipping needle was constructed in the year 1676 by Robert Normak, and some measurements were taken with it by Gilbert of Colchester (1540–1603), the "Galileo of magnetism."

It is well known that the loadstone can transmit to iron with which it comes in contact a permanent property like its own, and that the earth itself, as a larger loadstone, produces the same effect; so that, by placing a non-magnetic bar of soft iron in the line of the magnetic meridian, with its axis in the direction of the earth's force (*i. e.* parallel to the line of dip), it will be magnetized inductively, in such a way that its lower end becomes a north pole, and its upper end a south pole. Usually a certain proportion of the magnetism remains after the inducing force is removed.

The phenomenon of magnetization is, however, not confined to iron, but becomes apparent in other materials of which it forms a very small constituent. One of these materials, the ferruginous silicate of alumina, happens to have been—both baked and unbaked—the most extensively used for architectural and domestic purposes, in the shape of bricks and pots.

The ferrous-ferric oxide, which constitutes the magnetic substance of baked clays, possesses a great coercitive force, very little inferior to that of steel, that is to say, the power to store up and preserve the magnetic conditions under which it was baked.

Among these magnetic conditions, the most important, from an historic or even prehistoric point of view, is the magnetic inclination or dip because, as it slowly changes according to what we must assume to be a natural law, we have in terra-cotta a material giving us data to ascertain the age in which some of the objects made with it were baked, and the means to trace or follow the track of this law in prehistoric ages.

Towards the end of the seventeenth century, says the *Journal of the Royal Institute of British Architects*, R. Boyle knew that terra-cottas were permanently loadstones, magnetized according to the direction of the terrestrial magnetism in the place and time they were baked. In the year 1862–63, Gherardi published in our magazine, *Il nuovo Cimento*, some results of his experiences on the polar magnetism of brickwork in Turin, and of Etruscan and Roman terra-cottas, and announced the principle that baked clays retain magnetism in the same direction in which they first conceived it, even for centuries after they were baked.

The subject has lately been resumed, and some interesting experiments were made by Dr. Folgheraiter, the clever assistant of the Physicial Institute of the Roman University, who has extended his researches to many instances of brickwork of ancient buildings, palaces, temples, thermæ, and tombs of Rome and the Campagna, and ascertained that even volcanic rocks employed by Roman architects, such as tufa and lavas, in the primitive walls of Roma quadrata, in the basement stairs of the temple of Vesta in the Royam Forum, in the round temple at the Bocca della Verita, in the walls of Servius Tullius, in the Claudian aqueduct, in the Colosseum, etc., so well retain the primitive magnetic direction that in some cases it points exactly to inverted poles. We may here mention that Melloni, in examining the fragments of leucitophire and of other lavas employed in the amphitheatre of Pompeii, found them magnetized in every possible direction.

In order to familiarize himself with the subject, and to collect data regarding the way in which terrestrial magnetism became fixed in terra-cottas, Dr. Folgheraiter manufactured a series of clay cylinders of different sizes, and vases of different shapes, and had them baked in a vertical position and at different inclinations (see *Rendiconti della R. Accademia dei Lincei*, classe di Scienze, anno 1896). Then he applied the results of these investigations to some vases of the Etruscan epoch, which judging from their shape, had been baked in a vertical position. In four terra-cotta *cistæ* (eight century B. C.), preserved in the museum of the Villa Giulia, the south polarity was found prevalent round the base, and the north polarity at the top of the handle. *Oinochoai* of the same epoch gave the same results, which seem to prove that at the same and place where the vases were baked a magnetic needle would have dipped towards the south pole instead of the north one, as at present. The measurements made gave results which vary from 2°29′ to 25°37′, owing to the difficulty of making the corrections necessitated by the imperfections of the vases, and so could assign within very narrow limits the date of those vases, which from their peculiar shape had undoubtedly been baked in a vertical or otherwise determined position.

On the whole, the results of the investigations carried out at present on the history of magnetization point to the necessity of experimenting on materials which do not leave any uncertainty as to the date, place, and position of their baking. A series of such materials ought to be offered by brick walls which have been subjected to fire, such as the Great Council Hall of the Ducal Palace in Venice, burnt A. D. 1577, and of a great many buildings which suffered from the same cause, including some ancient Roman, and possibly even some Assyrian ones. Volcanic eruptions of historical date may also give us the means of ascertaining the magnetic dip, which they have fixed and embodied in cooling down into hard stone, and that which they have caused the structures to assume with which they came into contact, as is the case at Herculaneum.

Although some of these investigations can be carried out in Italy, their nature requires them to be extended over the largest possible field, and to the utmost limits of historic age. For this aeason I hope that the Royal Institute of

British Architects, recognizing the peculiar interest of the subject, and the possibility that some unhoped-for light may be thrown on the date of some important structures, or of the date at which the enemy destroyed them by fire, will ask its members to contribute a notice of such buildings that exhibit the magnetic dip produced at some period of their existence.

The cipollino columns of the Temple of Serapis at Pozzuoli have preserved for us a record of the geological changes of that territory. Let us hope that scientists may be able to point to some ancient monuments as historical archives of the law of terrestrial magnetism.

Note.—In studying the magnetism of terra-cotta vases, Dr. Folgheraiter has adopted the scheme of dividing into twelve parts the circumference of the base, and that of the mouth or upper rim of each vase (vases, be it understood, of symmetrical shape around a vertical axis at the moment of baking), and measuring the magnetism of each of these divisions of 30 degrees by means of a magnetic needle conveniently suspended and carrying a circular mirror, which serves for the reading of the variation by means of a theodolite.

The force of the positive and negative magnetism, the poles and the magnetic meridian of the vase being known, the magnetic inclination (dip) is reduced by calculating the resultant of the two vertical and horizontal components.

For instance, in subjecting to experiments a Greek amphora of the Museum of Florence, No. 1800 (about 650–500 B. C.), Dr. Folgheraiter read the following deviation:—

Around the base.	Around the upper edge (orlo).
+ 223°0	+ 211°0
178°0	179°0
121°5	130°0
8°0	44°5
— 119°5	— 66°5
215°0	134°5
223°5	147°5
190°5	118°0
147°5	74°0
1°0	+ 69 0
+ 149°5	155°0
+ 191°5	180°0

The maxima and minima of these numbers being considered to belong to the magnetic meridian of the amphora, the following diagram is obtained:—

+ 211°0 — 147°5

+ 223°0 — 223°5

the vertical component

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

FIREPROOF BUILDINGS.

BUILDINGS can be erected that are fireproof and absolutely safe against the ravages of fire. The question has been thoroughly considered by architects and the numerous experiments that have been made of late have convinced them that they have good reasons for this belief. The great Pittsburg fire of May 3 affords an interesting field of study for the architects and a writer in the *Engineering News* has improevd it. To realize the force of the conclusions drawn it is necessary to understand the character of the buildings burned. The fire broke out in a great grocery warehouse, which was slow-burning, but not at all fireproof, and filled with inflamable materials of great heat-producing qualities, like oil, molasses and hams. Separated from it by narrow streets were three office buildings of different types of fireproof construction. One had hard tile floor arches and covering for the steel framing, one porous terra cotta arches, and one concrete floor arch construction. The first named was a store, with an open front unprotected by iron

shutters and with floors undivided, so as to be practically a shell full of combustible material. The second was equally open and unprotected at the front, but had many four-inch terra cotta partitions, both longitudinal and transverse, above the ground floor. The third building was devided by wooden stud and metal lath partitions. While all three of these buildings suffered severely from the flames, the usefulness of the steel and terra cotta was revealed by a close examination of the buildings. The steel work, covered with terra cotta or concrete, suffered very little damage and the arches remained in position. All the buildings can be readily repaired. There was no twisting of columns. Of course, where fireproof buildings are full of light woodwork, as these seem to have been, the interiors will not be spared by the flames, and the natural conclusion is that it is absurd to call a building fireproof that contains any considerable amount of wood. In the case of these Pittsburg buildings, the flames found easy entrance because the large front windows and doors had no iron shutters. As soon as the glass cracked the interiors were doomed to destruction. It happened that the rear walls had small openings, with fireproof shutters. The iron in these was heated white and warped, but the flames went no further. The inflammable structures beyond were unharmed. Open floors in one building afforded plenty of opportunity for draughts, which spread the flames. Elevator shafts are especially dangerous in time of fire, but cannot well be dispensed with in tall buildings. The second building, by reason of its terra cotta partitions, suffered much less than the others. Terra cotta and concrete were both given a thorough trial at this fire and experts are unable to decide which better served the purpose of the builders. The chief necessity in fireproof buildings is to avoid unprotected openings in the walls through which the flames may enter; to provide fireproof partitions inside, and to enclose the elevator shafts, particularly at the bottom. After the architects have learned how to build an absolutely fireproof structure, they have still a harder task to convince the client who is paying for it that it is good economy for him to build as well as possible.—*Construction News.*

BOOKS AND PERIODICALS.

We have received from the CALIFORNIA STATE MINING BUREAU, San Francisco, San Francisco, Bulletin No. 12, containing a list by counties of the mineral productions of California for the year 1896. Compiled by Charles G. Yale from direct returns by producers.

Any resident of California can procure a copy by applying to the State Mining Bureau, San Francisco, inclosing a one-cent stamp for postage.

Annual Report of the Board of Regents of the SMITHSONIAN INSTITUTION showing the operations, expenditures and condition of the Institution to July, 1895. Washington—Government printing office, 1896.

This handsome volume of over 800 pages contains as usual a large amount of valuable information of a scientific and practicable nature appealing to the wants of the present time.

A description of the National Zoological Park with an illustration being a bird's-eye view of National Zoological Park from model; also a map of the locality showing adjacent properties give a very good idea of what has been done in the way of embellishment for this park in the District of Columbia. At present this park contains 520 animals on hand June 30, 1895—many of these animals were presented, some from Yellowstone National Park and some by exchange.

Space will not permit giving an extended review of this valuable work, but will call attention to an article that must attract a good deal of attention at the present time on account of our trouble with Japan—it is entitled "The Japanese Nation—A Typical Product of Environment."

AN OBNOXIOUS ORDINANCE.

THE RECENT ORDINANCE OF THE BOARD OF SUPERVISORS IN RELATION TO ROOFING.

WHAT ASPHALTUM MEN SAY.

THE RECENT action of the Board of Supervisors in passing an Amendment to the Ordinance in relation to roof covering on buildings in this city has occasioned a great deal of unfavorable comment and has been the leading topic of discussion among mechanics and all members of the building trades generally. Subdivision 1 of Sec. 30 of order No. 2927 has been amended to read as follows:

ROOF COVERING.

SUB. 1. The roof of all buildings hereafter erected within the fire limits, and the roofs of all brick or stone buildings hereafter erected within the City and County of San Francisco shall be covered with either metal, slate, tiles, terra cotta, or asphaltum, laid over felt, provided however that said asphaltum and felt shall be laid over a surface of either sheet asbestos, at least one-sixteenth (1-16) of an inch thick, tiling or other fireproof material, and shall in addition be covered with at least three-fourths (¾) of an inch of gravel screened through a screen the meshes of which shall not exceed one-half (½) of an inch square, to protect said roof of building from fire.

In Board of Supervisors, San Francisco, June 8, 1897.

After having been published five successive days, according to law, taken up and passed by the following vote:

Ayes—Supervisors Devany, Haskins, Delany, Sheehan, Lackmann, Morton, Britt, Smith, Rivers.

Excused from Voting—Supervisors Dodge, Rottanzi, Clinton.

This Amendment was vetoed by his honor, Mayor Phelan and returned to the Board on June 16th on the ground that such an ordinance savored too strongly of class legislation and was giving the members of one trade the power to make

the price of the labor of another. Despite the objections of the Mayor the order was taken up at the meeting of the board on June 28th and finally approved and passed by the following vote: Ayes—Supervisors Devany, Haskins, Delany, Sheehan, Lackmann, Rottanzi, Britt, Smith, Rivers. Noes—Supervisors Dodge, Morton, Clinton.

The Amendment, so it is claimed was prepared in the interest of the metal roofers of this city and was passed in direct opposition to numerous protests from property owners and the Asphaltum Roofers' Association; they are the most directly interested; as it is certainly an attempt to make asphaltum roofs less popular amongst owners owing to the additional cost, by the provision calling for asbestos or other fireproof lining beneath the felt. As this paper is committed to the defense of all home industries and home products, and as asphaltum is a very important product of this State, it was deemed proper to investigate the matter. The following interviews with some of the leading men in the Asphaltum Roofers' Association show that the sentiment amongst them is that they have been treated unjustly in the matter.

The Paraffine Paint Company is well and favorably known almost all over the entire civilized world, especially for their wood preserving preparations and fireproof roofing felt, and the universally known P. & B. Paint, which is conceded by all to be the greatest preservative paint ever discovered. The company has also been very successful with their pile covering material.

It is now nearly twelve years since this company prepared some of the piles for the Tiburon wharves and about three years ago they were inspected and found to be almost as perfect as when driven.

They are also interested extensively in the roofing business and also ship large quantities of refined asphaltum from their works, about 150 tons being exported by them to New York and Hamburg every year.

Mr. S. C. Irving, the manager of the company, who is also chairman of the Asphaltum Roofers' Association, when seen at the office of the company, 116 Battery street, expressed himself freely in relation to the ordinance and denounced it most forcibly as class legislation and against the interests of a particular line of trade, as well as a large number of taxpayers.

"All of the best buildings," said he, "were being covered with asphaltum and the metal workers commenced to kick, and backed by the International Metal Workers' Union and by the friendship of certain members of the Board of Supervisors, succeeded in having this ordinance passed. If allowed to stand it will add about $2.00 per square to the cost of asphaltum roofs, making them as expensive, if not more so, than tin; by this means, the tin roofers think they can retard the growth of our trade, besides giving the California asphalt mining industry a slap, for the benefit of imported tin. Last year we mined in this State $600,000 worth of asphaltum and that amount could be easily doubled if we had the market for it here. We filed a protest with the Board from property owners, signed by the largest real estate owners in the State, among which may be mentioned the following, as showing the class of taxpayers who favor our roofs: Union Iron Works, Crocker estate, Floyd estate, Sharon estate, Blythe estate, Pacific Imp. Co., Union Oil Co., etc.—but all to no avail."

Upon invitation, Mr. Irving appeared before the Board of Supervisors, who had agreed to grant the asphaltum men a hearing, but he was refused that simple courtesy; he, however, forwarded to the individual members copies of his argument against the adoption of the ordinance, in which he ably expressed himself as follows:

San Francisco, June 8, 1897.

To His Honor, the Mayor, and the Hon. Board of Supervisors of the City and County of San Francisco.

Gentlemen:—As representative of the Asphaltum Roofers of this city, as representatives of thousands of dollars of capital invested in the roofing business, as representative of over one hundred workmen employed by the Asphaltum Roofers, I desire to emphasize the protests which have been submitted to you to-day concerning the proposed change in that part of the fire ordinance which relates to the covering of roofs.

Asphaltum roofs have been used in this city for more than thirty years, and a large percentage of the wholesale business portion of San Francisco is roofed with them, and never during that long period has the Fire Department, the Fire Underwriters or the property owners of San Francisco complained of them as being a menace to the safety of the city.

In the large cities of the East the fireproof qualities of an asphaltum roof are so thoroughly recognized that in Boston, Philadelphia, New York and Chicago, it is estimated that over 90 per cent of the business blocks, warehouses, mills and factories are roofed with asphaltum roofs. For more than thirty years the Underwriters of the United States have in their table of rates made no distinction between buildings covered with asphaltum.

In fact, gentlemen, to day among the better class of architects, among the most careful property owners, the asphaltum roof holds a firmer position than it ever did, and it is for this reason that the opposition on the part of the metal workers to this class of roof has been developed.

It cannot be claimed for a minute that the metal workers and the importers of English tin are the only persons interested in the prevention of fires in San Francisco. The three classes of citizens who are most neeply interested in this subject are the property owners, the fire underwriters and the fire department.

The property owners have not asked for any change in the ordinance. We have submitted here a protest signed by property owners representing millions of dollars of taxable property in San Francisco. These property owners express themselves as being satisfied with the present ordinance.

The fire underwriters of San Francisco state that so far as their rules are concerned a building is a first-class building where all its exterior walls are built of brick, stone, adobe or concrete, and has a metal, slate, tile or composition roof.

The fire department has not asked for a change to be made in this ordinance. Chief Sullivan has submitted his report to you, in which he states that during his long experience he has not known of a fire being communicated to buildings through asphaltum and gravel roofs.

To all these citizens referred to above, the present fire ordinance is satisfactory. This fire ordinance was the result of careful investigation carried on by the heads of the fire department for a number of years, and after consulting the fire ordinances of the different cities of the United States, and, if I mistake not, of Europe and Australia.

In the proposed change your fire committee had added as a prerequisite to the lawful laying of an asphaltum roof the use of a sheet of asbestos 1-16 of an inch thick. This requirement is unjust both to the asphaltum roofers and to the property owners of San Francisco. Its addition does not increase the durability of an asphaltum roof, nor does it add to its fire proof qualities, but it does add to the cost of the roof, and is an unjust tax on the property owners who desire to have their buildings covered with an asphaltum roof.

If, however, this asbestos sheet is deemed essential by your Honorable Body under an asphaltum roof, experience shows that it is doubly necessary under a metal roof.

As shown by the disastrous fire which took place not long ago, where the fire is under the metal, the solder of the joints soon melts and the metal sheets part and create draughts, which add to the fury of the flames. Had that building been covered with an asphaltum roof the roof would not have opened up, but would have remained intact until its supports had burned away, and then would have fallen with a crash, smothering the fire, and aiding the fire department in controlling the situation. That this would have been the result is shown by the statement made by Fire Marshal Swenee of Chicago, who is the leading fire chief of the United States. He states: "I have seen all kinds of roofs tested and will say the standard Composition and Gravel roof from my experience will resist fire both inside and out more successfully than any other kind of roofing in use, except tile and brick when laid over a foundation of felt and composition. Taking all things into consideration, I think firemen can handle a fire more successfully under a gravel roof than under any other kind of a roof, except as above stated. The superiority of gravel roofs over those of metal placed over boards is best seen however when the fire is from the inside, in which case it not only serves to hold the fire in the building, but even when the support of the roof is completely burned away, the composition roofing in falling serves to smother the fire, while metal becomes loose and unsoldered under very little heat."

You, gentlemen, as property owners of San Francisco, and as citizens of the State of California, are anxious to promote the development of home industries, and yet the passage of this ordinance would mean to a large extent the destruction of vested interests, which employ a great number of men and keep considerable sums of money in circulation in this State, for not only do you discredit these products here, but you also discredit them wherever they may be shipped.

To take the place of these home products, you propose to compel the use of a foreign product, and a product which is hostile to this State's welfare, and for no other reason apparently than because a small class of self-interested individuals has asked for this change, individuals who are not interested in the safety of the City of San Francisco other than as far as it contributes to their private interests.

Now, gentlemen, in view of the statements made above, does it seem fair and just to us asphaltum roofers to pass an ordinance which is injurious to our interests and the interests of our clients, and for the benefit of another and smaller class of citizens? We think not, and we firmly believe that if your Honorable Body will carefully consider the case, it will deem that the best interests of this city and of the citizens of this city will lie in the maintaining of the present fire ordinance in relation to the covering of roofs.

We do not come here seeking your charity, but we do come here as the representative of a legitimate industry seeking justice.

Thanking you for the courtesies shown, we respectfully submit our case.

Respectfully submitted,

S. C. Irving,

Chairman Asphaltum Roofers Ass'n.

—*San Francisco Contractor.*

SOCIALISM AND COMMERCIAL ART.

AMONGST certain of our opponents no argument is more popular than that the advent of Socialism will mean the extinction of the artistic, a statement deducted from the fact that the Socialist propaganda generally ignores or contemns what is regarded as art in the present day. Such opponents, by seeming to prove their case so readily, doubtless influence the listening portion of an audience, and have a somewhat demoralizing effect even upon some Socialists. In the interest therefore, of the truth that looks below the surface of things, and to prove the unsoundness of this recurrent argument, it is necessary to enter somewhat fully upon the relationship which Socialism bears to the art of all time, as compared with that of the passing moment.

The stock answer to the statement is well known—that, whereas at present individuality is cramped into a groove and personal aspirations thwarted, Socialism will free both. The idea being that, while everyone must earn his living at the outset, the length of such working hours will be shortened, and facilities for development in any direction increased. It is further agreed that when an individual has shown such aptitude for producing work greateful to the senses as to fairly entitle him to be called an artist (in the specialized sense) he may be freed partly or entirely from the daily labor of "making his living," in order to devote his working hours to the beautifying of the public surroundings. Now, I consider that answer to be, in its way, perfect. Certainly it is merely general, but so is the criticism that called it forth. That which follows is put forward in the hope of affording a practical proof of this conclusion.

My first premise, that the opponent who makes use of the argument quoted has in his mind only whar is technically called fine art (music, painting, sculpture and so farth), may readily be granted, the loose phraseology of the time ignoring the claims to that title of most forms of art other than these. That every town and village, every house and street and garden, should illustrate either the collective or individual artistic sentiment of man; that every room in its furniture, and every human being in its dress, remind one of the loveliness of humanity, or rather act unwittingly on the minds of people by sheer fitness, does not ordinarily, I am afraid, enter his thoughts. Yet in this lies the very reason of the existence of art at all. There is no veritable sense of art in a community which conceives it to be a specialization, a thing for the edification of mere individuals, and yet it cannot be denied that at the present day art, the original property and birth-right of everyone born into the world, has become a matter of deep interest to a few, and utterly unknown to the many. This is a complete reversion of the proper condition of things, and just as Socialism has as its chief end the readjustment of the material means of life in order to properly supply the just needs of all, so it must also readjust the distribution of interest in things beautiful. It needs, then, but a hint to show that, as Socialism is aiming at the root of the material capatilistic system, it is (probably unconsciously) undermining all the art of the present day based upon that system. The parallel holds still further. Many Socialists speak of the coming communal state as a kind of reversion of what once was. It is pointed out that in savage communities the material necessities of life were held practically in common, and that state—modified by the advance already made—it is desirable to again realize through Socialism. At least one notable Socialist has put

his hand to it that in the realm of art also, that which has been must be again. The artistic Messiah who has so often visited the world, each time to die the death, must yet come again in a sort of glory to be lord over the earth. Both arguments are futile. The savage communal state can have no vital connection with the Social-Democratic community. Mediæval art has gone its way, and not a hundred Morrises can make it the art of the age of true freedom. Let us descend to particulars.

In its architectural design. What have we to boast of here? Miles upon miles of the most hideous villadom conceivable, piles of great buildings with no vestige of original idea—being nothing but senseless travesties of classic work, and finally, the most satanic erections of any historic age whatever, the four-square respectable abominations they designate "workmen's dwellings." This is the age that imagines itself imbued with the art of all the ages combined? The thing is a lie, a sham, of a part with the whole great lie upon which the pinchfork edifice of commercialism rests, and as certain to pass away in due course as filth and putrefaction is bound to be dissipated by pure air and bright sunlight in its turn. It will be said, and with perfect truth, that, admitting all this sham art and commercial hideousness, there are still true artists and earnest workmen doing good work in the world, and by their efforts should the time be judged. That is not so. True artists exist in spite of, not because of, commercialism. The fact that the "Banner of the Ideal" which they uphold is yelled at by the world until it is threadbare and outworn shows the nineteenth century artistic conceptions to be as sordid as its money-grubbing aim. By the time your earnest enthusiasts have forced their way to recognition and public acclaim, their fire has abated, their banner a mere wreck of what was, their place in the van taken by new spirits, who are trampled down in their turn. We do not find in the Athens of the Golden Age commercial companies exploiting their slaves by building "workmen's dwellings." They had slaves, and may have treated them ill, but this last great insult they did not—why? Solely because the national artistic instinct was too sincere and deep Not because their "hearts' bled for the deserving poor" (as the lords and ladies who live by the labors of those same poor, would say); not because their heads told them that clean houses meant a lower death-rate all round, but simply because an ugly building hurt the artistic eye—not of a few individuals, but of the nation as a whole.

A. W. POWELL.

London "Justice."

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

TESTIMONY BY ARCHITECT AS TO MATERIALS USED.—In a suit against the owner of a house by one to whom the contractor has assigned his claim subject to the claims of subcontractors and materialmen, the owner set up a defense that he had, since such assignment, paid sums due for certain materials. The court held that after proof that all of oneclass of such materials were furnished by a particular subcontractor, the architect might testify as to the quantity of such materials used in the house.

McCormick v. Sadler, Utah, 47 Pacific Reporter, 667.

WHAT WILL NOT REVIVE LIEN.—The right of a labor to a lien upon a building lost by the lapse of time cannot be revived by subsequent labor upon the building not performed by virtue of the contract with the owner.

Darrington v. Moore, Sup. Jud. Ct. Me., 34 Atlantic Rep. 419.

"OWNER" IN LIEN LAWS.—A party in possession of real estate under a bond for a deed will be deemed "the owner" of same for the purpose of creating a mechanic's lien upon it, as against a subsequent mortgagee of the same party.

Mulvane v. Chicago Lumber Co., Sup. Ct. Kas., 44 Pacific Rep. 613.

NOTICE OF MEETINGS.

BUSINESS MOSAICS.

Mr. James, the Pacific Coast representative of the J. L. Mott Iron Works can congratulate himself upon the fact that his company being established in 1828 has done more advance and improve the various branches of manufacturing in which they are engaged than any firm in their line of business. In proof of this statement we have only to examine the stock of goods in their show room 27, Flood Building, and compare it with that of others in the same line of business—for both room or kitchen—you will find what you want of the best. The motto of the firm appears to be "We take the front rank let others follow." Call and examine for yourself and you will be convinced of the truth of this statement.

Mike—I want to buy a hat. CLERK—Fedora? MIKE—No, not for Dora for Dinny.

Dixon's Silica Graphite Paint—In an examination of the Maria Kip Orphanage a few days since we could not but reflect what an improvement would have been made in the appearance of the building had the above paint been used for the roof instead of a bright red paint that has already faded. The lasting quality of the roof would doubtless have been greater to say nothing of the improved appearance.

"Why do you laugh at his jokes? It isn't possible you understand them, is it?" "No. But if I don't laugh, he'd try to explain them."—*Brooklyn Life.*

Bradley Bros.—Cement Laundry Trays, manufactured of the best Portland Cement, guaranteed not to leak, crack or sweat, can be found at their factory, 53–57 Tehama street between First and Second, San Francisco.

She—I don't know what makes her so positive? HE—Her sex.—*Puck.*

One can hardly walk in any direction in this city but they will find the use of cement has increased to an enormous extent in the past few years—sidewalks, garden walks, foundations and bulkheads all demand its use. W. R. Grace & Co., 203 California street are the headquarters of this article; if you want Josson, White Star, Scale, Comet or any of the best brands of Portland cement 203 California street is the place to find it.

Man (in barber shop)—I want a hair cut. BARBER—Why not have them all cut?

P. & B. Building Paper manufactured by Paraffine Paint Co., 116 Battery street, San Francisco. By the use of this paper you not only obtain a first-class building paper, the company claim there is none "just as good," but you patronize home industry, a doctrine that is becoming quite universal in our city where there is an increased desire to build up home manufacture and thus keep our money at home stead of sending it east for the benefit of eastern manufacture.

Colma Gulch. Construction of a levee to contain 26,000 cubic yards; owner, Spring Valley Water Works; architect, Engineer of Company; contractor, A. E. Buckman; signed, July 30; filed, Aug. 2; cost 20 cents per cubic yard.

Diamond near 17th. Two-story frame; owner, Ida L. Dillon; contractors, Douglass & Co.; signed, July 30; filed, July 31; cost $1560.

Dorland near Sanchez; One-story frame; owner, J. Egan; architect, O. Everett; contractor, R. Currie; signed, July 26; filed, July 26; cost $1650.

Eddy and Franklin. Changing two-story residence into two separate buildings; owner, Callaghan Estate Co.; architect, C. M. Rosseau; contractor, G. C. Nail; signed, Aug. 3; filed, Aug. 5; cost $4975.

Turk near **Mason.** Excavation, brick work, etc., for three-story brick; owner, Geo. G. Burnett; architect, James E. Wolfe; contractor, M. V. Brady; signed, Aug. 3; filed, Aug. 4; cost $5090.

Turk near **Mason.** Steel beams, etc.; owner, G. G. Burnett; architect, Jas. E. Wolfe; contractor, California Iron Construction Co; signed, Aug. 6; filed Aug. 9; cost $1460.

Union and Vincent. Two-story frame; owner, Jas. B. Wiseman; architect, D. C. Coleman; contractor, D. P. Benson; signed, Aug. 3; filed, Aug. 4; cost $2310.

Eddy and **Mason.** Stage in the Olympia Theatre; owner, A. Walterstein; architects, Salfield & Kohlberg; contractor, H. Behrens; signed, Aug. 4; filed, Aug. 5; cost $1500.

Eighteenth near Collinwood. Cottage; owner, Mrs. Clara Bennett; contractor, G. L. Bergren; signed, June 19; filed, July 15; cost $1048.

Eighteenth near **Diamond.** Frame building; owner, M. J. Barto; contractors, Sarcander & Thompson; signed, July 10; filed, July 17; cost $1200.

Ellis near **Gough.** Two-story frame; owner, Matthew Schwamm; contractor, C. Zwierlein; signed, July 16; filed, July 16; cost $5500.

Fell and **Lyon.** One brick and frame residence; owner, T. J. Clunie; architect, Wm. Curlett; contractor, Wm. Linden; signed, July 20; filed, July 20; cost $9812.

Fell near **Cole.** Plumbing, gasfitting, etc; owner, M. Keating; architects, Cahill & Condon; contractor, G. C. Sweeney; signed, July 20; filed, July 20; cost $1439.

Filbert and **Bay.** Addition to wharf; owner, Board of Harbor Commissioners; contractor, J. A. McMahon; cost $965.

Filbert near **Steiner.** Two-story frame; owner, Mrs. Margaret McBride; contractor, H. T. Grieb; signed, Aug. 6; filed, Aug. 7; cost $2000.

Flood Ave, No. 16, Sunnyside. Cottage; owner, J. D. Moreland; builders, McCarthy Co; cost $1200.

Folsom near **23rd.** Alterations and additions; owners, John A. and Wm. McCormick; architects, Heumann & Swain; contractors, Smith & Ely; signed, July 31; filed, Aug. 2; cost $710.

Fourth Ave. near **Clement.** Cottage; owner, William Alpen; architect, L. T. Fenn; contractors, Weste & Fenn; signed, June 12; filed, July 17; cost $1536.

Francisco near **Dupont.** Cottage; owner, W. H. Milestone; contractors, Morgan & Jackson; signed, July 8; filed, Aug. 3; cost $1525.

Front and **Pacific.** Two brick reel ovens; owner, Standard Biscuit Co.; architect, H. B. Maggs; contractor, J. A. Wilson; signed, July 17; filed, July 17; cost $3085.

Geary and **Stockton.** Interior store finish, etc.; owner, City of Paris; contractors, Home Manf. Co; cost $12,000.

Grove near **Fillmore.** Two-story frame; owner, John L. Koster; architects, Martens & Coffey; contractor, C. Schutt; signed, July 15; filed, July 16; cost $10,300.

Golden Gate Ave. near **Lyon.** Two-story frame; owner, Louis Kiefer; architect, C. M. Rousseau; contractor, R. J. Facert; signed, July 15; filed, July 16; cost $3230.

Golden Gate Ave. near **1st** Ave. One-story frame; owner, Harry Simpson; contractor, A. Dahlberg; signed, July 26; filed, July 26; cost $1085.

Greenwich near **Stockton.** Two-story frame; owner, Mrs. L. Thiel; architect, G. A. Berger; contractor, J. B. Penc; signed, Aug. 5; filed, Aug. 6; cost $2400.

Hardy near **16th.** Two one-story frame cottages; owner, J. M. Comerford; cost $3000.

Hancock near **18th.** Inside finish, painting, etc; owner, T. A. Bermingham; contractor, R. Fahy; signed, Aug. 9; filed, Aug. 10; cost $510.

Harper near **30th.** Cottage; owner, M. S. Moc; contractor, Ed. Stephens; signed, Aug. 5; filed, Aug. 11; cost $1500.

Hoffman Ave. near **24th.** Two-story frame; owner, Christina M. Dettner; contractor, L. F. Williams; signed, Aug. 3; filed, Aug. 4; cost $1225.

Hyde and **O'Farrell.** Alterations and additions; owner, Mark Sheldon; contractor, C. W. Duffie; cost $1000.

Jackson near **Buchanan.** Mantels and wood finish for two-story frame; owner, L. and E. Emanuel; architect, W. H. Lillie; contractor, I. Stassberger; signed, July 6; filed, July 31; cost $1888. Plumbing; contractors, Ickelheimer Bros; signed, July 6; filed, July 31; cost $1340. Painting; contractor, J. H. Keefe; signed, July 7; filed, July 31; cost $1215.

Joost Ave, No. 42, Sunnyside. Cottage; owner, Mrs. Laura J. Woods; builder, H. H. Easter; cost $2000.

Joost Ave No. 215, Sunnyside. Cottage; owner, W. A. Hicks; builder, H. H. Easter; cost $1200.

Kearny and **Sutter.** Plastering, etc; owners, Adams Co; architect, H. A. Schulze; contractor, Jesse E. Sisera; signed, July 22; filed, Aug. 2; cost $2558. Electric lighting; contractor, Electric Lighting Co; cost $1920. Painting; contractor, R. J. Getz; cost $2750.

Laguna near **Filbert.** Two-story frame; owner, Joseph Rolch; architects, Salfield & Kohlberg; contractor, L. M. Weisman; signed, July 17; filed, July 19; cost $1540.

Leavenworth near **Filbert.** Alterations and additions; owner, F. Passe; architects, Salfield & Kohlberg; contractor, H. Behrens; signed, July 29; filed, July 31; cost $2690.

Lombard near **Gough.** Cottage; owner, H. Krause; architect, C. A. Meussdorffer; contractor, F. L. Beach; signed, July 12; filed, July 17; cost $1400.

Market and **Spear.** Carpentor work, etc., for five-story brick; owner, W. W. Young; architects, Kenitzer & Barth; contractor, A. C. Hussy; signed, July 21; filed, July 21; cost $8126. Brick and terra cotta work; contractor, Richardson & Gale; cost $14,370. Steel and iron work; contractors, Western Iron Works; cost $26,370. Terra cotta work; contractors, Gladding, McBean Co; cost $8250. Concrete work; contractor, G. Goodman; cost $11,580. Excavations, piling, capping, etc; contractors, Healy, Tibbitts & Co; cost $10,572. Cut stone work; contractors, Raymond Granite Co; cost $11,265. Plumbing and gas-fitting; contractor, W. F. Wilson; cost $1080. Fire proof floors; contractors, San Francisco Fire Proofing Co; cost $8947.

Market and **Noe.** Seven stores and a church tower; owners, Trustees Trinity M. E. Church; contractor, John O. Dyar; signed, July 15; filed, July 16; cost $3425.

Market near **Taylor.** Three-story brick; owners, Silverman Bros; architect, M. J. Lyon; contractor, W. J. Field; signed, July 24; filed, July 27; cost $1000.

Market near **4th.** Alterations to Emporium Building; owner, The Emporium and Golden Rule Bazaar; architects, Pissis & Moore; contractor, F. W. Kern; signed, Aug. 2; filed, Aug. 3; cost $2515. Fixtures in stock room; contractor, Fred Miller; signed, Aug. 2; filed, Aug. 3; cost $3125.

Maple Street. Two-story frame; owner, M. Marmuth; architects, Kenitzer & Barth; contractor, G. Peterson; signed, Aug. 6; filed, Aug. 11; cost $2545.

Montgomery and **Sutter.** Plumbing, etc; for three-story brick; owner, A. L. Whittell; architects, Townsend & Wyneken; contractor, W. F. Wilson; signed, July 15; filed, Aug. 5; cost $1242. Galvanized iron work; contractor, J. Guilfoy; cost $1000.

Montgomery street No. 419. Repairs; cost $1000; days work.

Mission near **23rd.** Interior copper wainscoting; owner, Mission Masonic Society; architects, Hermann & Swain; contractor, Jas. Guilfoy; cost $1200.

Pacific Ave. and **Buchannan.** Plumbing, etc.; owner, Albert Meyer; architect, Salfield & Kohlberg; contractor, H. Williamson; signed, July 29; filed, Aug. 2; cost $2014.

Peoples' Homestead Assn. Cottage; owners, Joseph J. Magee and Eliza J. Magee; contractor, T. F. Mitchell; signed, July 30; filed, July 30; cost $1226.

Powell Ave. near **California** Ave. Alterations; owners, Lawrence Boyle and wife; contractor, A. O. Brown; signed, July 1; filed, July 15; cost $1240.

Powell and **Geary.** Galvanized iron and tin work; owner, Mrs. Charlotte F. Clark; architect, P. Schwerdt; contractor, J. Guilfoy; cost $1500.

Sacramento near **Spruce.** Two-story frame; owner, C. P. Fonda; contractor, P. Rive; signed, July 19; filed, July 20; cost $2009.

San Bruno Road near **Erie.** Cottage; owner, John E. Eberle; architect, D. C. Coleman; contractor, J. Kenealy; signed, Aug. 2; filed, Aug. 4; cost $1145.

Scott near **Fulton.** One-story frame; owner, R. B. Kittrege; architect, W. O. Banks; contractor, A. G. Johnson; signed, July 27; filed, Aug. 3; cost $1750.

Second Ave. near **Clement.** One-story frame; owner, Charlotte S. McLaughlin; contractor, M. C. Power; signed, July 15; filed, July 16; cost $1600.

Seventh and **Mission.** Excavation for Post Office; owner, United States of America; architect, United States Architect at Washington; contractor, San Francisco Bridge Co.; cost $36,830.

Sixteenth and **Mission.** Alterations and additions; owners, Pattolsen Co; architects, Martens & Coffey; contractor, R. Trost; signed, July 15; filed, July 17; cost $5195.

Spreckels Ave. No. 1, Sunnyside. Cottage; owner, H. H. Easter; cost $1200.

Stevenson near **13th.** Two-story frame; owner, P. Strickert; architects, Salfield & Kohlberg; contractor, L. Thoenges; signed, July 15; filed, July 15; cost $2320.

Stevenson near **3d.** Concrete work for power house; owner, Claus Spreckels; architects, Reid Bros; contractor, Gray Bros; signed, June 28; filed, July 17; cost $3020; with addition of 15 cts. per square foot for basement floor.

Stevenson near **3d.** Excavations, stone and concrete work for two-story brick; owner, San Francisco Gas and Electric Co; architect, Engineer of Co; contractor, J. H. Wilson; signed, July 28; filed, July 29; cost $6017. Carpenter and mill work; contractors, Campbell & Pettus; signed, July 28; filed, July 29; cost $1188. Roofing, etc; contractors, Henshaw Grant Co; signed, July 28; filed, July 29; cost $575.

Tenth near **Harrison.** Two-story frame; owner, Mrs. Susan McClasky; contractor, John Flaherty; signed, July 26; filed, July 26; cost $1700.

Thirteenth Ave. near **Lake.** One-story frame; owners, Henry and Augusta Pape; architect, H. Hess; contractor, A. G. Anderson; signed, July 17; filed, July 24; cost $1304.

Thirteenth near **Stevenson.** Two-story frame; owner, Mrs. Julia E. Spinney; architect, C. M. Rousseau; contractor, P. L. Roberts; signed, July 31; filed, July 31; cost $3050.

Thirtieth near **Merced.** Cottage; owner, Chas. T. Jurges; architect, C. Koenig; contractor, Chas. J. N. Koenig; signed, Aug. 3; filed, Aug. 4; cost $1220.

Turk near **Scott.** Additions; owner H. Miller; contractor, H. Behrens; cost $1000.

The California Architect and Building News.

OFFICE, 408 CALIFORNIA STREET, SAN FRANCISCO, CAL., U. S. A.

VOLUME XVIII. SEPTEMBER 20th, 1897. NUMBER 9.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

Published on or about the 20th of each month by The California Architectural Publishing Company. The Stockholders being Architects and others interested in the profession.

SUBSCRIPTION TO THE JOURNAL, - $3.00 PER YEAR IN ADVANCE.

ESTABLISHED 1879. INCORPORATED 189
NOW IN THE EIGHTEENTH YEAR.

OLIVER EVERETT Secretary

ADVERTISING RATES:

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

A ZOOLOGICAL Garden in the City of San Francisco is no doubt a very good idea and the wish for it should be gratified at as early a date as possible. All cities of the size of San Francisco should be provided with such gardens.

But a greater desideratum yet is the provision of small gardens for recreative purposes scattered amongst the residence part of the city. Fortunately the layers out of the city were farseeing and liberal and provided a number of these in the northern half of ihe City but for some reason or accident left the Mission district unprovided for. Now this matter wants attending to at once, before the prospective rise in real estate takes place—there is no doubt there are some vacant blocks yet left, that could be had cheap—e. g., there are some steep hilly places which it is very costly to cut down so as to make possible for dwellings; these could be made very picturesque parks.

However the agitation for any grounds that involve any large amount of money now is out of place—for the wants of our sick and destitute are of paramont importance over any matter of mere pleasure or even scientific interest. The accommodation required foremost at this time is a good public hospital built with all the appliances and arrangements which characterize a modern hospital, and made such a place that citizens should be able to go there without fear and dread as they go to the present one.

Meanwhile, notwithstanding the shocking state of our present hospital, much could be done in regulating it; and those unfortunate enough to need its use should be treated humanely and courteously and not be at the mercy of any tyro of a medico who may have charge of a patient's case, neither should his recovery be jeopardized for the sake of an exhibition for medical students.

THE FOLLOWING editorial, under the title "Peddling Bids" recently appeared in the *California Contractor*.—"Sub-contractors have a very just cause of complaint in a system which appears to have recently grown up among contractors of pressing or sweating their sub-contractors in a novel and unprofessional manner. They call for bids on a certain job and receive a number from snb-contractors. They then take the lowest bid and go to the man who is next lowest and showing it to him, ask if he cannot get down a notch lower than that; this particular sub-contractor consents to give him a lower bid. This bid is then used to operate the same way on the first mentioned contractor, who figures his bid down lower still and so gets the job, not, however, till about all the profit is squeezed out of the job and the figures at which the work is taken come to be dangerously near presenting a margin of loss to the contractor.

"Of course no reputable contractor would do such a thing as this yet the fact is that it is done by some. It is difficult to see how this sort of business can be prevented except by ascertaining the identity of those contractors who do this thing and letting them become known, then securing an agreement among the sub-contractoes not to figure on any of their jobs. Perhaps if they were known, the architects might hesitate before they would award a contract, for one who would act quasi dishonestly would not have far to go to act dishonest all the way, should the opportunity be favorable. The understanding, when a bid is handed in, of course, is that each man is to stand upon what he has offered and if the sub-contractors who are solicited to give a lower bid would resolutely refuse to do so, of course that would settle it. But the severe competition in business these time forces men to take work almost for the sake of keeping at doing something and they are loath to let any opportunity go however scant such may be. Peddling bids is one of the products of the times. In good times men would neither attempt it, nor respond to the solicitations."

The evil complained of by our contemporary is an evil inherent in our system of so-called civilization. It is the logical and inevitable result of competition, and as long as competition rules our business life as it does to-day, there will be no hope of a better condition of things.

The work undertaken by the original contractor is frequently obtained only through similar means to those he in turn is forced to use towards his sub-contractors. Business is done on the principal of "Do your neighbor, or he'll do you." A modern novelist has just written a book to prove that a christian life cannot be lived under existing conditions. The fact is too self-evident to need argument. Such being the fact, is it just to blame the individual instead of the system of society that is the true cause of the trouble. Suppose nine-tenths of the contractors and a similar proportion of the sub-contractors should agree to change their methods and stand out for a proper price, what would be the result? Simply that the other one-tenth would secure a practical monopoly of the work. Nor is this true of any one line of business only; it is universal. Read the following statement by John P. Altgeld as another illustration:

"During the strike of 1894 one of the largest operators in Illinois stated that he had some excellent men in his employ, who had families to support, who were sober and industrious, and who had not beeen able to make over $8 a month for a year past. The majority of the operators were not to blame; they had to compete in the market in order to sell their coal; they had their money invested in mines and in mining machinery; they found that a few unscrupulous and conscienceless men had taken advantage of the hunger of the miners and got them to go to work at starvation wages, and were thus able to put their coal upon the market at greatly reduced prices. This forced the honest, humane, honorable men engaged in the mining business to sell their coal at a similar price or go out of the business, and the result was they likewise had to reduce wages. So that it was the unscrupulous and conscienceless men who fixed the wages."

PORTLAND CEMENT.

BY RICHARD TAYLOR—READ BEFORE THE GORDON COLLEGE SCIENCE CLUB.

ALTHOUGH Portland Cement is the subject I intend making a few remarks about, I will, in the first instance, leave the word *Portland* out, and say a few words about cement. Cement is a substance which is capable of assuming a liquid form, and of being applied between the surfaces of bodies so as to unite them firmly when solidifying, such as glue, paste or shellac, bnt the cement I wish to speak about is one which has for its chief constituent carbonate of lime; in fact carbonate of lime and cement are so closely allied that it is impossible tc speak of one without touching upon the other; therefore I will first of all direct your attention to carbonate of lime.

Carbonate of lime occurs as a mineral in all geological ages, and it is very widely and abundantly distributed all over the globe. In its natural state it is largely used for building purposes, and when burnt it becomes quicklime, which is used for hundreds of different purposes in our arts and manufactures.

Limestone is divided into many qualities but for the present purpose I will only make three divisions :—

1st. The fat or rich.
2d. The poor.
3rd. The intermediate or hydraulic.

1. Fat or rich lime is that which is most free from foreign matter; when water is poured on a piece it hisses, crackles, and swells, gives off a quantity of hot vapor, and quickly falls to pieces. It increases two or three times in bulk, and if placed in a vessel of water, it falls to the bottom and always remains soft.

2. Poor lime does not increase in bulk when water is poured over it, in fact water scarcely affects it at all; neither does it harden the water.

3. Intermediate or hydraulic lime develops no heat when water is poured over it, nor does it increase in bulk; when, however, it is placed in a vessel of water it becomes a hard solidified mass after a few days, and will continue to harden for months.

To summarise these classes, we have

1. The fat or rich, which does not harden in water, and which will contain over 90 per cent of carbonate of lime.

2. The poor, which is in no way affected by water, and contains less than 50 per cent of carbonate of lime.

3. The intermediate or hydraulic, which when burnt and ground sets in a hard mass when put in water, and contains from 70 per cent to 80 per cent of carbonate of lime.

Smeaton is undoubtedly the engineer to whom we are mostly indebted for our knowledge of hydraulic lime. His great work in rebuilding the Eddystone Lighthouse necessitated him using a lime that would set and become hard in water, and up to that period it was a somewhat doubtful point as to which limes did set in water; one of the commoner ideas was that the harder the limestone, the harder the mortar would ultimately become. Smeaton first tried experiments with a rich lime of undoubted repute for building purposes, but he found that when it was exposed to the action of water it was quite useless. During his searches in the various lime districts he stayed one day with a farmer who told him that the lime in his district was quite unfit for agricultural purposes, and what they used had to be carted a distance of forty miles. On enquiring as to the reason he was told that when the local lime was ground and put on the land it became quite hard after the first shower of rain. This was sufficient to give Smeaton a clue to work on, and he was not long in carrying out a series of experiments, which satisfied him that it was only the intermediate or hydraulic lime which became hard in water. He soon found that limestones containing about 70 parts of carbonate of lime were best suited for hydraulic purposes, and that the remaining 30 parts were an argillaceous clay. Further experiments were then made to see if it were possible to make an artificial hydraulic lime, and for this purpose a fat rich lime was taken and clay added until it became an intermediate lime—in otner words, clay was added to a limestone of 90 per cent until it only contained 70 per cent of carbonate of lime. This, on being burnt and ground, set hard under water and gave a proof to Smeaton that the hydraulic properties of lime were due to its containing certain proportions of clay. These were the experiments that formed the foundation of our present knowledge and method of manufacture of cement and Portland cement.

About this time Roman cement came into use, and this is nothing more or less than an intermediate lime containing, perhaps, rather an excess of clay. It is made from a natural stone found on the east coast of England near Harwich, and called Septaria. There are large deposits of this stone all over England, and there is a small quantity of it to be found in Port Phillip Bay, at Mornington. Lias lime or Lias cement is another intermediate lime, which probably more closely resembles Portland cement in its constituent parts None of these natural hydraulic limes were burnt at a high temperature; they were usually burnt at about the same temperature as ordinary lime. If by any chance any of the material was overburnt, it was thrown on one side as useless, so it was the aim of the burner to get as little overburnt material in his kiln as possible.

About the year 1824, a bricklayer name Aspdin, of Leeds, carried out a number of experiments with artificial hydraulic lime; by chance he ground up some of the overburnt parts—pieces which were burnt to a cinder and which, up to that time, everyone had been careful to exclude. He was surprised to find that these pieces not only set when put in water, but that they set infinitely harder than when only burnt to the same degree as ordinary lime. He was so satisfied that he immediately took out a patent for the manufacture of artificial hydraulic lime, and in his specification, when describing the process, he calls it "Portland cement." This is the first mention we have of Portland cement, and this industry, started in so small a way some sixty years ago is now one of the great commercial industries of the world In its early days it had many difficulties to contend with., especially from the makers of Roman cement, who opposed it by every means that lay in their power. Cases occurred where it failed to do its work, and in more than one instance it gave disastrous results, houses and walls that were built with it collapsing, until people were suspicious and afraid to use it. However, difficulties and troubles were one by one overcome, and many engineering feats which have since been executed, could never have been carried through without its aid.

Portland cement as manufactured to-day is in principle the same as that made by Aspdin, the only difference being in the details, but it is these details which constitute the difference between a good and a first-class cement. The name Portland cement is altogether misleading, and a better term would have been hydraulic or water cement. The name comes from its similarity in color and texture to a building stone extensively quarried at Portland, in the south of England.

To briefly summarize the process of manufacture, I will describe the method carried out at Fyansford as being in our immediate neighborhood. A rich lime containing about 90 per cent of carbonate of lime is thoroughly and carefully mixed with clay, and water is added for the purpose of moulding it into bricks. These bricks are dried and burnt in kilns until they become vitrified; the vitrified bricks or "clinker" are ground, and the resulting powder is cement.

Having roughly gone through the mode of manufacture, we now come to the point when it is delivered to the consumer, and also to the time when testing is requisite.

The tests generally specified are :

1st. Tensile strain.
2d. Soundness.
3rd. Fineness.
4th. Chemical test.

There are other tests, perhaps as equally important, but these fourlare the commonest.

The first test is carried out by making briquettes, which have a sectional area of one inch in the smallest part. These briquettes have to stand a breaking strain of 350 lbs. in 7 days, and 550 lbs. in 28 days. Some engineers require only 300 lbs., while others demand 400 lbs. in 7 days, but 350 lbs. and 550 lbs. will represent a fair average of the standard requirements. Care and manipulation are requisite in making briquettes, and I am sorry to say that instances have come under my notice in this colony where so-called experienced testers have not been able to get a breaking strain of one single pound out of a briquette, while, with proper handling, briquettes made from the same bulk, on the same day, in the same room, and with the same appliances gave a strain of over 400 lbs.

Briquettes are made in the following way :—the cement is gauged with a minimum of water, say from 15 per cent to 20 per cent, and it is put in brass moulds with all speed : the more quickly this operation is performed the better will be the results. For the first 24 hours they are covered with a damp cloth or put in a zinc-lined box—in any case they must not be put in the sun, or wind, or before the fire, so that the moisture can be dried out of them. At the end of the 24 hours they are put in water, where they remain until broken. When removed from the water for the purpose of testing, break them at once; if this operation is delayed an hour or two the breaking strain will be reduced. Such items as the temperature of the air, and of the water used, and the

speed with which the briquettes are made, affect the breaking strain.

I expect some gentleman present will say what is the use of all these tests; it is impossible to use cement in actual practice under such conditions, and it is unnecessary to get a cement giving a breaking strain of 550 lbs. to join two bricks together, when the bricks themselves are not half as strong. Now the object to be gained is to find out the very best results that can be obtained from a certain cement under the most favorable conditions. The foregoing are the standard tests, and provided ever sample is used in the same way, and under the same conditions, it is easy to get at the comparative values of the different brands.

It is a mistake to think that because a cement gives a high breaking strain at an early date it is therefore of more value than one which gives a low or moderate strain, for very often it is just the reverse. A cement that gives 650 lbs. in 7 days only gives 600 lbs. in 28 days, 550 lbs. in three months, and in this way gradually lose strength, until at the end of twelve or eighteen months it has all crumbled away, and has no more cohesion in it than sand. It is far safer to have a sample that will show a moderate strain at an early date, and slowly but continually increase in strength; say 350 lbs. in 7 days, 550 lbs. in 28 days, 700 lbs. in three months, and so on. High breaking strains are obtained by the admixture of a heavy percentage of lime; but it is quite possible to overstep the limit, and if your cement contains more lime than can be neutralized by the silicas, etc., you get free lime, which, while showing great strength to start with, ultimately disintegrates and rots the bulk away.

The test for soundness is an important one; it is carried out by making a small round disc, termed a "pat," about three inches in diameter and a quarter of an inch thick. Mix it with a minimum of water, work it up well, and put it on a piece of glass. This like the briquette, must be kept away from the sun, fire, or any hot dry place. At the end of 24 hours it is put in water and examined from day to day. If at the end of 7 days it shows no signs of cracks or blowing, you can pass it as sound; if, however, there are cracks, further examination is necessary to ascertain the cause. The chances are that the cement is too new and fresh, and if it is allowed to mature for a few days by spreading a sample out in a thin layer, these cracks will not appear with the next pats. If the cracks do occur again, be very chary about using the bulk.

Test for fineness. The usual specification is that it shall be ground so fine as to leave no residue on a sieve having 2500 holes to the square inch, and that not more than 10 per cent will remain on passing it through a sieve having 3,600 holes to the square inch. As a rule manufacturers grind to a far greater degree of fineness than this standard. The fineness of grinding largely determines its usefulness as a constructive material, for it is well known that the finer a cement is ground, the better will be the result obtained when mixed with sand. There is a growing demand for finer cement, but it must be remembered that finer grinding means extra wear and tear on the machinery, and consequently an increased cost.

The chemical test is often of corroborative value in estimating the properties of a sample; at the same time it is a test which is of more use to the manufacturer than to the consumer. The chief constituents of a cement are about—

Lime, 60 parts.
Silica, 24 parts.
Alumina and iron, 12 parts.

The remaining four parts are composed of alkalies, magnesia, and carbonic acid. The alkalies will not average more than 0·75 per cent, and although present in so small a quantity they play a very important part, as they form a flux for the lime and the silica.

You often hear the term "set" applied to cement. It is a very ambiguous one. "Set" usually means the ultimate hardness due to its nature attained by a substance originally in a liquid state. Cement, however, does not attain its ultimate strength for years, so the word in this case has a different signification. Cement sets in a few minutes, or hours; after that it hardens. A very common test to apply to cement to see if it is set is to press the pat with the thumb nail. The proper method is to use the Vicat needle, which is a weighted steel rod of about a quarter of an inch in diameter. The rod is suspended over the pat and allowed to fall on it like the monkey of a pile-driving machine, penetrating the sample until such time as it is sufficiently set to withstand any impression. With regard to a quick or a slow setting cement, this must be determined by the nature of the work for which it is intended. The characteristics of each are that a quick cement will probably attain a fair strength in a short time, but will not improve much afterwards, while the slower setting sample will not do so well as the quick one at an early date, but will eventually attain much greater strength. Cement may be rendered slow in setting by exposing it to the air, but such treatment does not give to a quick-setting sample the characteristics and the ultimate strength of a naturally slow one.

The uses Portland cement is put to are numerous, but in any case it is seldom used in its neat state. For the engineer it is in constant demand for foundations, piers and harbor works, in the shape of concrete. Concrete is composed of an aggregate (such as broken stone), sand and cement in varying proportion according to the class of work to be executed. A very small specification is three parts of aggregate to two of sand and one of cement. This, when set, makes an extremely hard and compact mass. The builder more often uses the cement mixed with sand only, for laying bricks or plastering walls in the proportion of two or three parts of sand to one of cement.

It is sometimes contended that there are instances in which the addition of sand in small quantities improves the cement. Such instances are however quite the exception, for sand can but be regarded as a diluent, and the only reason that can be urged for its use is on the score of economy by the admixture of so much cheaper a material.

These are the chief uses, and I should like to enumerate a few of the abuses, for cement is often asked to do work it was never intended for. One of the most frequent causes of failure in making concrete is the use of unsuitable aggregates, such as a soft sandstone, or a half decomposed basalt or stone overgrown with vegetable matters. Another great trouble is the sand. Sand for concrete or mortar should be entirely free from both loam and clay. Do not take sand out of the road or ditch, or a fine drift sand; neither let it be round-grained or soft. To obtain the best results use a coarse, sharp, angular sand such as one gets from quartz rocks. The greatest enemy to cement is loam, clay or dirt, and it is of the utmost importance that the aggregates or sand should be washed perfectly clean before being used. Too much importance cannot be laid upon this point. A very common practice on the mining fields in this colony is to use the so-called sand or sludge from the mullock heaps. At the best of times this sand is quite unsuitable, having been ground to a very fine state by the stampers, and to use it direct from the heap without washing is throwing good money away, for ordinary lime would answer just as well.

Again in hot weather cement commences to set very quickly, and to get first class work it is necessary to have it in its allotted place as soon as possible after the water has been added. This necessitates mixing a very small quantity at a time, a practice workmen do not care about, and often a larger quantity is gauged than can be used before the setting action commences. The result is that more water is added, to the detriment if not the total destruction of the setting properties of the cement. When cement begins to set crystals are formed, which, when united, becomes one solidified mass, and when the setting action once commences the less the mass is disturbed the better. Another evil is in not having the walls thoroughly wetted when plastering. The water that is added to cement is put there for a purpose—to make it set; now if you put this mortar on to a dry wall the bricks readily absorb a great deal of the water, and deprive the cement of what it requires in order to set and harden.

In the summer months, in a hot climate, plastering and even brickwork in cement, should be well hosed down with water every day or so after the work is done, and on a north wind day no outside plastering should on any account be allowed.—*The Wombat.*

TESTS OF THE WEARING QUALITIES OF FLOORING MATERIALS.

MR. FRANK Furness, the well known architect of of Philadelphia, lately carried out an extremely valuable series of tests to determine the relative durability of various flooring materials. The experiments were made on May 15th, by Messrs William Gray & Sons, large contractors for stone work in Philadelphia, says *Pacific Coast Wood and Iron*. All kinds of material possible for use in flooring were tested and the results proved very interesting as well as instructive. The samples were all placed face downward upon a horizontal iron rubbing wheel 10 feet in diameter, which was run for a space of one hour at a speed of 75 revolutions per minute. A suitable frame held the blocks loosely in place ahd prevented them from rotating with the wheel, care being taken to let the full weight of the blocks bear upon the wheel. The face of the wheel was freely supplied during the test with sharp rubbing sand and water and the friction produced was most intense. The results were all important and many extremely peculiar, the behavior of the marble and mosaics especially. They could not withstand the action of the wheel and their average resistance, indeed, was not as high as that of the woods.

One of the most curious results is shown in the action of the woods, where teak lost nearly double as much as the softer white pine, the wear being respectively 13-16 and 7-16 of an inch. Yellow pine showed the same wear as white pine, and the oak specimen lost the same amount as its great rival Oregon pine, which was reduced by 5/8 of an inch.

FIRE PREVENTION.

FIRE Prevention, an article on this subject in the *Pacific Coast Wood and Iron*, says it is well to have at hand a simple contrivance for extinguishing a small fire at its start, making the suggestion that the use of bottles filled with the following solution to serve as hand grenades:—Take twenty pounds of common salt and ten pounds of Sal Ammoniac (Nitrate of Ammonia to be had at any druggist)and disolve in seven gallons of water.

Sal Ammoniac is, as any druggist will tell you, Chloride of Ammonium, an entirely different substance from Nitrate of Ammonia which would rather add to the danger of a conflagration than surpress it.

THE EMERY SUPPLY.

THE bulk of the world's emery is obtained from the island of Maxos, in the Mediterranean. Its hardness prevents it from being dug out or even blasted, so fires are kept burning around the blocks until they crack, when they are pried open with levers, the process being repeated until the blocks are reduced to a cubic foot or less. Three hundred men are engaged in the work, but no bachelor miner can be admitted to the fraternity, which is composed exclusively of benedicts.—*Architecture and Building.*

Preachleigh—What do you expect on the day of judgment? Spendthrift—Supplementary proceedings.—*Truth.*

VANDERBILT'S FORESTS.

THE BILTMORE WOOD DOWN IN NORTH CAROLINA—HINTS BY WHICH LUMBERMEN MAY PROFIT.

WHERE is no doubt that the Vanderbilt forest and arboretum in North Carolina constitute together one of the greatest undertakings that have ever been attempted by individual enterprise the world over; and ex-Secretary Morton of the United States Bureau of Agriculture, has himself declared that nothing owned by sovereign or subject will compare with it.

There are 110,000 acres of woodlands on the Biltmore estate, says *Milwaukee Journal*, according to the report of the North Carolina State Board of Agriculture, just issued, and the plan and endeavor will be to carry out only those exact principles of forestry which apply as well to Government forests as to timber owned by lumbering firms.

Mr. Vanderbilt has undertaken to furnish the highest possible example of the science of tree culture in every one of its branches; and to this end he has divided his immense tract into two distinct parts, each to be treated by entirely different methods. The first, containing 10,000 acres, lies in the valley of the French Broad river, and is known distinctively as the Biltmore forest. The merchantable timber has been cut out in former years, and so it was decided to grow only firewood there, an ample market being wide open in Asheville, and other near-by towns. The trees are chiefly oak and pine, and as the pine grew the fastest, the oaks were given a start when sapplings by growing them in separate groups, or by cutting back the pines when they

threatened to overtop and kill the oaks. A sufficiently dense covering has to be kept at all times so that the soil may not deteriorate. The other, and larger tract of nearly 100,000 acres, lies almost entirely in the mountains; and is known as Pisgah forest, so called from Mt. Pisgah dominating, which has an elevation of over 5,000 feet.

These are virgin woods and the timber is of large size, some trunks attaining seven feet in diameter, with frequent groups of yellow poplars averaging three or four feet in diameter. There are cherry, curly walnut, hickory and various valuable furniture woods in great abundance.

On this division the forestry department is growing only timber trees, and under this system the amount of eith timber or firewood which shall be cut is fixed by what is known as the "sanctioned annual yield." From the amount of wood fiber added to a tree each year it is quite possible to deduce the amount of wood added to the whole forest each year. If no more than this increment is cut, the forests cannot be diminished. No trees are taken under a specified diameter. The mother trees are left to seed the ground again, which they do most liberally in that particular climate and location. Add, most important of all, the undergrowth is especially looked after. Every tree is felled carefully, the smallest possible amount of danger is done and the uuderbrush is sedulously cleared away.

Here are hints by which the lumbermen of the big woods and north shore might profit. Inordinate gain will alone tempt inordinate haste, else we could all secure from now on a lasting revenue. But odd-zooks! It is so much less trouble just now to haul out the logs this year, let the toppings lie and the fires run! And for the hereafter? Well, we discover simply a charred and unproductive waste.

Up to date the United States has been behind all other nations in the care and management of their timber lands but under the prospects of the great emoluments which this beginning in forestry forecasts (all praise to the genius who inspired it), the country may well congratulate itself that the scheme of segregating large forestry areas of the public domain, to be cared for by the Government, has not miscarried after all; and that the superlative reservations are to stand as defined by the Forestry Commission, except that entries may be made for milling purposes—a provision which is eminently proper and satisfactory.

Within six years a tree nursery has been established on the alluvial flats of the Swannanoa river, near Asheville, and since the erection of the first propagating house, between 3,000,000 and 4,000,000 of forest trees and shrubs have been turned over to the planters, and the annual output may now be estimated at something over 2,000,000 of plants. These are almost inconceivable figures, and yet they constitute only some of the preliminary steps toward the establishment of a vast museum, of living trees and shrubs, to be called the Biltmore Aboretum, in which will be living examples of every species and subspecies of woody vegetation, indigenous and introduced, that will thrive unprotected in the soil and climate of the locality. The line of display will appear like a continuous highway or drive traversing the valleys and slops for a distance of twelve miles, including loop roads; and on either side, extending back for 200 feet or more, will be arrayed the trees and shrubs on permanent exhibition in their fullest perfection and pride of life, in isolated specimens in small masses and in bulk.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

SKETCH of Residence on Clay street, Samuel Newsom, Architect.

RESIDENCE for Mr. Parker, Marinita Park, San Rafael, Samuel Newsom, Architect.

HOLY CROSS CHURCH, Cahill & Condon, Architects.

AT THE request of Mr. Cuthbertson we state that through a mistake of the lithographer the title of his "Study of a Church" in our last number was wrong. W. J. Mathews is the architect of St. John's Episcopal Church, Oakland.

WOLSEY AND ARCHITECTURE.

WOLSEY'S taste and knowledge of architecture must have been great. Who can see the tower of Magdalen College and doubt it? And Christ Church and Hampton Court, though mutilated, bear sufficient testimony to his knowledge and love of that excellent art of architecture which none but superior minds should venture to meddle with, for if it makes greatness and wisdom conspicuous to the world, it makes folly so too, and therefore the more contemptible. Architecture is the natural constructive instinct of a great mind, the throwing off into palpable form of high thoughts. It is part of that noble constructiveness which would build up institutions, the practical language of a governing mind. It is an empire in itself, in which genius

loves to reign and be supreme. It was highly characteris- of Wolsey. We believe all really great men love architecture. A man who builds to himself a notable palace or house, and by his arrangements adequately shows forth and appropriates a fine estate, makes to himself at least a centre of the world, to which all things come or seem to come, and from which all thoughts radiate by enclosing apparently so much of the world's wilderness as he wants; all within his eye's reach is his real, and all without his imaginary domain. He creates the happiest delusion of space, regulates it by his own ideas, making it what he would have it and ornaments it to charm him. In a fair and noble mansion a man must, in some degree, feel himself a king, for his will has sway and room to move in. It has a tendency to elevate, to give him character, decision and that dignity which ever arises from repose within one's self; that need not be shoved and hustled from meditation and reflection by the too near proximity of ill-assorted things and persons. We look upon the taste for architecture as a national good. It is the means of raising families to a visible responsibility, giving them something to keep up and to hand down to others, greater than the littleness of uncultivated, unadorned republican man. The other arts require it, and all arts thus assisting each other, build up and constitute all that is beautiful in the world, visible and moral. How hard is it to give up anything we make and call our own. Now in nothing was Wolsey's superior greatness more shown than in the readiness of so large a sacrifice as Hampton Court. Had he pride, he had enthroned it here, but his pride was a part of him. Driven out forcibly from one palace, it had a sure refuge in himself. Nothing, no outward act of malice or tyranny, could rob the world's history of Wolsey. He knew it, and even in his fall was greatest. The noble fabric of Hampton Court was, however, readily resigned by Wolsey into the king's hands, who subsequently seized, too, his palace afterward called Whitehall. It is a curious fact, and one that marks a visible retribution upon things, names and persons, whereby a sort of moral history of the world is written by a divine hand and carried on in continuance by striking incidents; it is a curious fact that these two palaces of Wolsey, as they are monuments of the rapine of royalty, so they are of the humiliation of royalty.—*Tesseræ, in London Architect.*

THE PLACE OF RESEARCH IN EDUCATION.

ALTHOUGH the advice given below is from an Englishman's point of view in regard to education it is nevertheless applicable to our own schools.

From an interesting article entitled "The Place of Research in Education" published in the last report of the Smithsonian Institution we extract the following:

"There can be no question that the future of this country is very largely in the hands of its schoolmasters and schoolmistresses, and there are many among us who are convinced that our progress is much hindered by their failure to feel the pulse of the times—who think, indeed, that they do not suitably prepare the material which we subsequently are called on to mold into its final shape. We look to the new commission to recommend drastic changes which will enable us to utilize to the full the marvelous ability latent in the English race, and which will help parents in solving the truly terrible problem with which they are confronted in these days of unreasoning and unreasonable competition when the time comes to secure a career for their children. English boys and girls at the present day are the victims of excessive lesson learning, and are also falling a prey, in increasing numbers year by year, to the examination demand, which threatens to become by far the most ruthless monster the world has ever known either in fact or in fable. Ask any teacher who has to do with students fresh from school his opinion of them, he will say that in the great majority of cases they have little if any power of helping themselves, little desire to learn about things, little if any observing power, little desire to reason on what they see or are called on to witness; that they are destitute of the sense of accuracy and satisfied with any performance however slovenly; that, in short, they are neither inquisitive nor acquisitive, and as they too often are idle as well, the opportunities offered to them are blindly sacrificed. A considerable proportion undoubtedly are by nature mentally very feeble, but the larger number are by no means without ability, and are in fact victims of an acquired disease. We must find a remedy for this state of things or perish in the face of the terrific competition now setting in.

"Boys and girls at school must be taught from the very earliest moment to do and to appreciate. It is of no use our teaching them merely about things, however interesting—no facts must be taught without their use being taught simultaneously; and, as far as possible, they must be led to discover the facts for themselves. Instead of our placing condensed summaries in their hands, we must lead them to use works of reference and acquire the habit of finding out: they must always be at work applying their knowledge and solving problems. It is a libel on the human race to say, as many do, that children can not think and reason, and that they can only be taught facts; early childhood is the time at which these faculties are most apparent, and it is probably through failure to exercise them that they suffer atrophy. The so-called science introduced into a few schools in answer to the persistent demands of its advocates has been in most cases a shallow fraud, of no value whatever educationally. Boys see oxygen made and things burnt in it, which gives them much pleasure; but, after all, this is but the old lesson learning in an interesting shape, and has no superior educational effect. I would here repeat what I have recently urged elsewhere, that in the future all subjects must be taught scientifically at schools, in order to inculcate those habits of mind which are termed scientific habits; the teaching of scientific method—not the mere shibboleths of some branch of natural science—must be insisted on. No doubt some branch of chemistry with a due modicum of physics, etc., is the subject by means of which we may, in the first instance, best instill the scientific habits associated with experimental studies, but it must be true chemistry of the discoverer, not the cookery-book-receipt pseudoform which has so long usurped its place. Whatever be taught, let me repeat that mere repetition work and lesson learning must give place to a system of allowing children to do things themselves. Should we succeed in infusing the research spirit into our teaching generally, then there will be hope that, in the course of a generation or so, we shall cease to be the Philistines we are at the present time; the education given in our schools will be worthy of being named a 'liberal education,' which it never will be so long as we worship the Old World classical fetish, and allow our schools to be controlled by those who reverence this alone, having never been instructed in a wider faith."

COLOSSAL BRICK STRUCTURE.

VERY few know it, but it is a fact, says the Washington *Star*, that the Pension Office Building is the largest brick building in the world. It has been subjected to much criticism, but it can stand it, for as time passes along there are many things seen about it that escaped notice when it was newer. In all there are over 10,000,000 bricks in the building.

General Meigs took liberties with bricks that no other architect had ever attempted. He not only used bricks exclusively for the building, but he used them in constructing the stairs throughout the building. In the matter of stair building bricks have often been used for the riser, but the step has alway been of iron, wood, slate or stone. In the Pension Office both riser and step are of brick. As a brick building, therefore, pure and simple, it is unique in construction, outside of the fact that it is the largest exclusively brick building in the world.

BOOKS AND PERIODICALS.

Weeping Ferry by Margaret L. Woods, is the complete novel in LIPPINCOTTS' for September, a story that had better not have been written. The other articles are of interest. The complete novel for the October number which is promised to be ready September 22d, is entitled A Knight of Philadelphia by Joseph A. Altsheler author of The Sun of Saratoga.

Journal of the WESTERN SOCIETY OF ENGINEERS for August, contained a very interesting article entitled Deep and Difficult Bridge and Building Foundations, by Geo. E. Thomas, M. W. S. E. The illustrations are very good and caenot fail to interest engineer and others engaged in like work.

THE WOMBAT, is the singular name of a little magazine that comes to us from Australia, it is published by the Gordon Technical College and the Allied Associations. An article on Portland Cement by Richard Taylor in the July number of the magazine will be found in another part of our journal.

NOTES AND COMMENTS

ONE IS glad to hear that Mr. Ruskin is in good health, and that he takes daily walks in the neighborhood of Conington. The addresses he delivered some years ago at Oxford on landscape painting are at length to be printed. The reason given for their tardy publication is that Mr. Ruskin has not until recently been satisfied with the progress made in the art of photogravure, it being of course, necessary to have reproductions of those pictures to which he referred. The volume will contain eighteen large plates, including some reproductions from Turner.

CHARLES KNORR, a Chicago architect, killed himself so his creditors could get their pay out of his insurance policy. This is a most delightful system. It certainly equals the suttee custom of the natives of India—where the wives burned themselves on the funeral pyre of their husbands.

"One of the troubles of this period," said the ever-confident politician, "is that we have too much labor-saving machinery." "That's true," replied the ordinary citizen. "There are too many political bosses with schemes to save the people the trouble of thinking for themselves.—*Washington Star.*

FIGHTING FIRES IN TALL BUILDINGS.

AT THE recent convention of the fire chiefs, held in New Haven, Conn., the principal matter under consideration was fighting fires in tall buildings. The large number of these buildings erected of late years in our cities has made this a vital question in case of fire, and while but few of these buildings have actually been destroyed in this way, yet what has been done has shown the utter inadequacy of the departments to meet the demands made upon them in such cases. The general opinion expressed was that laws should be passed restricting the height of such buildings. Legislation against such structures was strongly advocated. It was also advocated that the insurance companies make concessions in favor of buildings of moderate height. No other branch of the city service appreciates more fully the danger from fire that goes with buildings of such immense height, and it was claimed that some day there will be a fatality in a sky-scraper that will appall the world. The part of wisdom is to prevent by law the erection of any structure beyond the number of stories that is consistent with safety and the capacity of fire apparatus.—*Architecture and Building.*

CORRESPONDENCE

The Editor is not responsible for any opinions of Correspondents.

To the Editor of the California Architect and Building News.

I had a few moments to spare while waiting for the San Rafael boat this morning and I strolled along in front of our new depot. I admired the beautiful proportions and the good construction, I thought what a credit it was to the architect, the late A. Page Brown, other works of whom I had often admired; I came to the main entrance and on a huge stone my eye caught some lettering which I found was a statement that the building was build by the present Board of Harbor Commissioners, a Mr. Holmes, engineer, and Mr. Swain the architect; the intention seems to be to ignore the real architect altogether. I do not think this ought to be allowed and I do not think it will be when the matter is understood. Yours truly,

SAMUEL NEWSOM, Architect.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

SUIT FOR QUANTUM MERUIT.—On a quantum meruit—for the amount of work done—on the erection of a building, the owner is entitled to an allowance for attorney's fees incurred in consequence of the failure of the contractor to defend a mechanic's lien filed against the building by a subcontractor.

Dempsey v. Schawacker, Mo., 38 Southwestern Rep. 954.

If a contractor seeks to recover on a quantum meruit, after being denied the opportunity to finish his contract, he must prove what work he did, its value, and that it was not paid for; he cannot throw on the one sued the burden of showing what he omitted under consract.

Wyckoff v. Taylor, 43 N. Y. Supp. Rep. 31.

EVIDENCE AS TO HEATING APPARATUS.—On an issue as to the sufficiency of a heating apparatus to properly warm a building, where it was claimed that its failure was due to the faulty construction of the building, evidence of the comparative results obtained from such plant and another subsequently placed in the same building is admissible.

Kramer v. Messner, Iowa, 69 Northwestern Reporter, 1142.

WHEN COTRACTOR IS NOT LIABLE FOR INFERIOR BRICK.—A building contractor's right to recover the contract price is not defeated by the fact that the bricks purchased by him, in good faith, and used in the building, were made of inferior clay; the defect not being discovered by careful inspection, nor until developed by exposure to the weather after the building was completed.

Wis. Red Pressed Brick Co. v. Hood, Minn., 60 Northwestern Rep. 1091.

NOTICE OF MEETINGS.

OSCAR LEWIS, Pres. JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday even ing of each month.

ADAM BECK, Pres. M. V. BRADY, Sec.

BUSINESS MOSAICS.

If we look backwards to the year 1828, it is surprising to see how little was required in the plumbing line to make homes comfortable. Now this was the year that the J. L. Mott Iron Works was established in the State of New York; ever since that time this firm has been striving to increase the good qualities of articles so essential to the health, comfort and happiness of our people until it appears impossible to make a further advance; still we never can predict certainly of the future, and know not what may be in store in the way of improvements. Nevertheless, those who may be about to fit up their dwellings for health and comfort would do well to call upon Mr. M. S. James who is the Pacific Coast representative of the above named company. A glance at his advertisement on page v of this journal will convince the most prejudiced that they cannot do better than call and see Mr. James at his office, room 27 in the Flood Building.

"Spicer must be fearfully superstitious—he never comes near his office on Friday." "Superstitious nothing! That's the day he tells the collectors to call."—*Chicago Journal.*

Roche Harbor Lime for sale by all the principal dealers, said to be the purest in the world—first-prize awarded at the World's Fair as well as from various other fairs from New Orleans to Washington. For particulars address Tacoma and Roche Harbor Lime Co., box 289 Builders' Exchange, 40 New Montgomery street, San Francisco, Cal.

She—I wonder who first said "It is better to be born luckg than rich?" He—Some old fool whose wife married him for his money, I guess.—*Cleveland Leader.*

The Rischmuller Door Opener and Closer is so well and favorably known that it is hardly worth while to call attention to its merits, nevertheless it may be well to give some of the advantages claimed for this contrivance. As there are two wires used, one for opening and the other for closing the door, it will be seen that the door is under full control. It is perfectly burglar prof as the wires do not run below the floor, and therefore the door cannot be opened from the basement.

A full seized working model can be seen at 320 Nineteenth street, orders should be left with Geo. Rischmuller, at that address.

She—Mr. d'Auber is wedded to his art. He—Well, there's nothing mercenary about the union.—*Life.*

It looks as if before this century is out that the swearful wobbling door knob, which rattles when touched will be a thing of the past—for now come the Patent Screwless Door Knob which is as firm as the rock of Gibralter—immovable and unrattleable.

As well as being a Godsend to the householder and tenant, it is also to the carpenter who will now be saved that niggling handling of small screws which tries his patience; it is labor saving and money saving which says it is in line with modern progress.

Does away with washers and screws and can be adjusted at once to any thickness of doors, fits all locks, and can be removed almost instantaneoesly by any one. It is worthy of all attention.

"Me an' Billy don't have to study 'bout Alasky this year." "Why not?" "Pap's done wore th' map o't our gogafy."—*Free Press.*

Joseph Budde, the manufacturer of sanitary appliances in the plumbing line can be found at his old stand 575 Mission street—architects and others are cordially invited to call at his sample room. He claims that home industry is encouraged when employment is given to this establishment every dollar remains at home.

Mr. Budde is successor to Wm. Smith late of 21 Montgomers street, also of W. B. Rustemeyer & Co., known as the Pacific Water Closet Works, 126 Main street. His motto "First-class work, low price and two years guarantee of all my work!" should make him popular with his customers.

He—What strain is that? She—(playing on the mandolin)—That was no strain; only an ordinary effort.—*Examiner.*

The color effect in Cabot's Creosote Shingle Stains has been very ingeniously illustrated in a colored chart preparod by Samuel Cabot of Boston, Mass. This might be called a movable chart as by turning the leaf the same building is shown in different colors. This chart, like all the work turned out of Mr. Cabot's establishment, is first-class. Nothing could be more convincing of the merits of Cabot's Shingle Stain as the division of the plates allows sixteen separate and distinct combinations to be seen—enough to give a very clear idea of the blending of the various colors.

Subscribe for California Architect and Building News—$3.00 Per Year.

The Pacific Refining and Roofing Co., 113 New Montgomery street, San Francisco, advertise on page vii of this journal, W. P. Shingle Stains and also W. & P. Creosote Paints. The stain is in soft and pleasing tints, of the highest grades of materials, specially adopted to use on redwood, is a Pacific Coast product.

The Creosote Paints are an excellent wood prevervative, for use on surfaces new or old. A first class wood and shingle covering in soft shades resembling state.

Minnie—Nellie is a regular genius. She put her frizzes up in tin foil off champagne corks. Madge—And way off champagne corks? Minnie—Because it makes 'em tight.—*Judge.*

Joseph Dixon Crucible Co., Jersey City, N. J., are always having something new on hand, the latest novelty is Brazing Graphite. Not a little of the expense in brazing is due to the cost of removing the brass which has stuck to the metal where it is not wanted, The removal of this brass is usually attained only by patience and diligent filing. Now comes to the aid of the brazier that unique mineral, graphite, which is not affected by acids, alkalies, heat or cold. Braziers who have made use of Dixon's Pure Flour of Graphite pronounce it worth its weight in gold. A sample will be sent without charge by the Joseph Dixon Crucible Co., Jersey City, New Jersey, who are the only manufacturers.

Sierra Lumber Company corner of Fourth and Channel streets, manufacturers of and dealers in doors, windows, and blinds, also sugar pine, yellow pine, spruce and fir lumber to order.

She—I know that I am not good-looking, but people forget my face when I sing. He—Won't you sing now?—*Fliegende Blatter.*

Dunham, Carrigan & Hayden Co., 17 and 19 Beale street, San Francisco. In their advertisement on page ix of this journal is shown an illustration of their American Sliding Door Hanger for which they claim unusual advantages—great saving of time and expense, and superior excellence in operation. It is trackless, no wheels and also no noise, what more can be wanted of a door hanger? This firm are dealers in the Yale & Towne Manfg. Co's. Celebrated Yale Locks.

"Johnie, I hope you are not beginning to swear?" "Oh, no, not till I am as big as papa!"—*This Wittie World.*

Samson Cordage Works, Boston, Mass.—manufacture Samson Spot Cord, it can be told at a glance and is warranted free from waste and imperfections of braid. Send for samples, 115 Congress street, Boston, Mass.

CITY BUILDING NEWS.

Ashbury near Fredrick. Cottage; owner, T. Wollweber; architects, Kenitzer & Barth; contractor, C. Schutt; signed, Aug. 18; filed, Aug. 19; cost $4880.

Brazil Ave. and Lisbon. Cottage; owner, Mrs. C. Murphy; architect, Thos. McKee; contractor, D. R. Perry; signed, Aug. 28; filed, Aug. 30; cost $1237.

Broderick near Sacramento. Two-story frame; owner, T. G. Cockrill; contractor, E. W. Hyde; signed, Aug. 11; filed, Aug. 13; cost $2700.

Buchanan near Broadway. Two-story frame; owner, Chas. H. Huffman; architects, Percy & Hamilton; contractors, Thomas H. Day & Son; signed, Aug. 13; filed, Aug. 14; cost $4650.

Buchanan and McAllister; Excavation, brick work; owner, Mrs. Louis Junker; architect, C. Haupt; contractors, Gray Bros; signed, Sept. 8; filed, Sept. 8; cost $1596.

Brighton near Holloway. To build; owner, Employee of the branch jail; builders, McCarty Co; cost $3000.

Capp near 24th. Two-story frame; owner, Sarah A. Lawson; architect, F. B. Wood; contractor, Allan De Lair; signed, Aug. 12; filed, Aug. 13; cost $3395.

Capp and 19th. Two-story frame; owner, C. F. Wm. Fahrenkrug; architect, E. J. Vogel; contractor, I. W. Coburn; signed, Sept. 8; filed, Sept. 8; cost $3276.

Chelsea Place near Busn. Three-story frame; owner, Babette Federlein; architect, C. A. Meussdorffer; signed, Aug. 17; filed, Aug. 18; cost $3400.

Church and Clipper. Cottage; owners, Jas. Linden and wife; contractor, John Kenally; signed, Sept. 7; filed, Sept. 13; cost $1060.

Clay and Pierce. Excavation, brick and iron work; owner, Caroline Wingerter; architect, A. C. Lutgens; contractor, Fred Wagner; signed, Aug. 30; filed, Sept. 2; cost $1500.

Clay and Pierce. Carpenter work for two-story frame; owner, Caroline Wingerter; architect, A. C. Lutgens; contractor, J. B. Cogswell; signed, Aug. 30; filed, Sept. 3; cost $4800.

Clayton near Hayes. Two-story frame; owner, Mrs. Wilhelmine English; architects, Hill & Bowers; contractor, F. W. Kern; signed, Aug. 11; filed, Aug. 14; cost $3850.

Clement near 7th Ave. Cottage; owner, R. E. Donohue; contractors, Marcuse & Remmel; signed, July 28; filed, Aug. 31; cost $1400.

Clementina street No. 525. Alterations; owner, Mary Menihan; architect, A. J. Barnett; contractor, Chas. Alsup; cost $1000.

Devisadero near Washington. To build; owner, Frank Kayser; architect, C. M. Rousseau; contractor, W. R. Kenny; signed, Aug. 25; filed, Aug. 27; cost $2800.

Diamond near Sussex. To build; owner, Mrs. F. Smith; contractor, D. Ross; signed, Aug. 18; filed, Aug. 19; cost $1540.

El Dorado and Rhode Island. Office building, bins, etc; owner, Sanitary Reduction Works; architect, Chas. Thackery; contractor, Maccono & Rosso; signed, Aug. 12; filed, Aug. 13; cost $4722.

Ellis near Mason. Brick work, etc., for six-story brick; owner, L. H. Sly; contractor, Thomas Butler; signed, Aug. 28; filed, Sept. 1; cost $9965.

Eighteenth near Castro. Two-story frame; owner, W. C. Johnson; contractor, W. B. Helbing; signed, Aug. 31; filed, Sept. 1; cost $3050.

Eugenia near San Jose Road. One-story frame; owner, Wm. Henly; contractor, C. M. Lee; signed, Sept. 7; filed, Sept. 8; cost $1195.

Fell near Masonic Ave. Two-story frame; owner, B. F. Hawes; contractor, C. Zwierlein; signed, Aug. 21; filed, Aug. 25; cost $4500.

Foerster, Lakeview. Cottage; owner, W. B. Peel; builders, McCarthy Co; cost $1200.

Fredrick near Cole. Two-story frame; owner, Susan Jaenicke; architect, C. F. Robertson; contractor, T. T. Pottinger; signed, Set. 8; filed, Sept. 8; cost $3254.

Golden Gate Ave. near Baker. Cottage; owner, S. G. Seovern; architect, John McHenry; contractor, Thos. Kinread; signed, Aug. 16; filed, Aug. 23; cost $1500.

Golden Gate Ave. near Buchanan. Alterations and additions; owner, Samuel Rainey; contractor, P. Rive; signed, Sept. 10; filed, Sept. 11; cost $1375.

Grove near Fillmore. Plumbing, etc; owner, John L. Koster; architects, Martin & Coffey; contractor, W. F. Wilson; signed, Aug. 27; filed, Aug. 30; cost $1477.

Green near Polk. Cottage; owner, I. H. Goldmeyer; contractor, Geo. M. Salsbury; signed, Aug. 18; filed, Aug. 21; cost $1650.

Guerrero and 26th. Two-story frame; owner, D. J. Shine; architect, C. M. Rousseau; contractors, Thayer & Hughes; signed, Aug. 17; filed, Aug. 19; cost $3673.

Haight near Scott. Two-story frame; owner, G. F. Hanekamp; architect, J. E. Kraft; contractor, J. Wuelfken; signed, Aug. 18; filed, Aug. 21; cost $3240.

Howard near 25th. Alterations; owner, Geo. L. Payne; architect, N. Blaisdel; contractor, Geo. Harris; signed, Aug; 12; filed, Aug. 16; cost $8075.

Jackson near Centeral Ave. Two-story frame; owners, Frieda Stauf and C. C. Dohrmann; architect, N. Blaisdell; contractor, C. Krecker; signed, Sept. 11; filed, Sept. 11; cost $6840.

Jones near Lombard. Three-story frame; owners, Caroline E. G. Jacques and Thomas G. Jacques; contractors, A. W. Pattiani & Co.; signed, Aug. 14; filed, Aug. 16; cost $4639.

Jones near Chestnut. Two-story frame; owner, Peter H. Fleming; contractor, N. G. Chadwick; signed, Aug. 30; filed, Aug. 30; cost $3500.

Jones near Greenwich. Three-story frame; owner, Conrad J. Bill; contractor, H. T. Grieb; signed, Sept. 8; filed, Sept. 8; cost $3530.

Juniper near Folsom. Two-story frame; owner, Mrs. Mary J. Anic; architect, F. P. Rabin; contractors, W. Horstmeyer & Co; signed, Aug. 28; filed, Aug. 28; cost $1200.

Laguna near Washington. Grading, brick work, etc; owner, Dr. A. Barkan; architects, Plasis & Moore; contractor, F. W. Kerr; signed, Sept. 1; filed, Sep. 2; cost, $13,240.

Lakeview (Ingleside). Cottage; owner, Chas. Zissig; contractors, McCarthy & Co.; day's work; cost $3000.

Lee Ave., Lakeview. Cottage; owner, G. G. Unsworth; builder, McCarthy Co; cost $2000.

Lyon near Golden Gate Ave. One-story frame; owner, J. P. Simmons; architect, M. G. Bugbee; contractor, W. Sorensen; signed, Aug. 18; filed, Aug. 19; cost $1200.

Lyon near McAllister. One-story frame; owner, Janet Sutherland; contractor, T. A. Born; signed, Aug. 25; filed, Aug. 27; cost $1618.

Liberty near Castro. Cottage; owner, Jacob Bauer; contractor, W. W. Redhall; signed, Aug. 31; filed, Aug. 31; cost $1830.

Market near Kearny. Alterations; owners, S. N. Woods & Co; architect, M. J. Lyon; contractors, Campbell & Petus; signed, Aug. 14; filed, Aug. 17; cost $2700.

Maple and California. Steam power, etc; owner, Hospital for children, etc; architect A. C. Schweinfurth; contractor, J. G. Grannis; signed, Aug. 23; filed, Sept. 13; cost $3585.

Mission and Precita. Two-story frame; owner, John Collins; contractor, E. N. Jones and J. A. Cotter; signed, Aug. 26; filed, Aug. 27; cost $2550.

Mission and Second. Excavations, bulkhead, etc; owner, Wells, Fargo & Co; architects, Percy & Hamilton; contractors, Buckman Contracting Co; signed, Aug. 27; filed, Aug. 27; cost $1700.

Mission near 2d. Concrete work, etc, for four-story brick; owner, Robert Dalziel; architect, J. W. Mathews; contractor, Geo. Goodman; signed, July 28; filed, July 31; cost $5570. Brickwork, etc; contractor, R. W. Beattie; signed, July 28; filed, Aug. 31; cost $3169. Cast iron work; contractor, Judson M'f'g. Co; signed, Aug. 19; filed, Aug. 31; cost $4700. Carpenter work; contractors, Bignami & Masow; signed, July 17; filed, Aug. 21; cost $5183.

Ninth near Bryant. Two-story frame; owner, Wm. Garms; architects, Salfield & Kohlberg; contractor, H. Munster; signed, Sept. 8; filed, Sept. 8; cost $3270.

Oak and Devisadero. Moving a building; owner, Mrs. S. Mish; architects, McDougall Bros; contractor, John H. McKay; filed, Aug. 12; cost $1700.

Pacific Ave and Buchanan. Painting; owner, Albert Meyer; architects, Salfield & Kohlberg; contractors, J. St. Denis Co; signed, Aug. 7; filed, Sept. 13; cost $10197.

Plymouth near Patton. One-story frame; owner, Martin T. Cooney; contractor, Cornelius March Lee; signed, Aug. 10; filed, Aug. 20; cost $1280.

Post near Lyon. Two-story frame; owner, John Mahoney; contractor, J. T. McInnes; signed, Aug. 28; filed, Aug. 30; cost $2650.

Richmond Ave, block 8 lot 26. Cottage; owner, W. A. Hicks; contractor, McCarthy Co; cost $1000.

Sansome and Pine. Alterations and additions; owner, Royal Insurance Co; architects, Percy & Hamilton; contractors, A. J. Forbes & Son; signed, Sept. 3; filed, Sept. 3; cost $1644.

Sanchez near 17. Dwelling and stable; owner, Martin Nolan; architects, Townsend & Wyneken; signed, Aug. 17; filed, Aug. 18; cost $2055.

Seventh and Mission. Fence around Post-office block; owner, U. S. Government; contractor, J. A. Smilie; cost $1445.

Seventh Ave, near M street. To build; owner, Patrick Hallinan; architect, M. J. Welsh; contractor, J. B. Quinn; signed, Aug. 21; filed, Aug. 21; cost $2650.

Stevenson near 4th. Steel and iron work; owner, Claus Spreckels; architects, Reid Bros; contractor, Pacific Rolling Mills; signed, July 14; filed, Aug. 20; cost $6421. Brick work; contractors, Peacock & Butcher; signed, Aug. 2; filed, Aug. 20; cost $5515.

Stockton and Geary. Grading, concrete, etc; for 6-story brick; owner, Union Trust Co; architects, Pissis & Moore; contractors, Cushing-Wetmore Co; signed, Sept. 1; filed, Sept. 4; cost $2300.

St. Mary's Ave, near Mission. To build; owner, Rev. Peter D. Brady; architects, Shea & Shea; contractors, Barrett & Leahy; signed, Aug. 28; filed, Aug. 31; cost $5505.

Sutter near Kearny. Alterations and additions; owner, A. W. Rose; architects, Percy & Hamilton; contractor, B. F. Ellis; signed, Aug. 21; filed, Aug. 23; cost $1532.

Tenth Ave, near Clement. Cottage; owner, George Hensel; architect, A. J Barnett; cost $1500, day's work.

Third and Market. Marble and slate work; owner, Phoebe A. Hearst; architect, A. Schweinfurth; contractor, Vermont Marble Co; signed, Aug. 27; filed, Sept. 3; cost $9989. Plastering, cementing, etc; contractor, J. R. Tobin; signed, Aug. 31; filed, Sept; 3; cost $13,200. Metal stair case work; contractor, Western Iron Works; cost $3885.

Third Ave. near Lake. Cottage; owner, E. D. Feil; architect, H. D. Munson; contractor, W. R. Kenny; signed, Aug. 13; filed, Aug. 14; cost $1545.

Third near Market. Alterations and additions; owner, Hyman Bros; architect, Percy & Hamilton; contractor, B. F. Ellis; signed, Aug. 13; filed, Aug; 13; cost $4321.

Turk near Mason. Carpentry, etc; for 3-story brick; owner, Geo. G. Burnett; architect, James E. Wolfe; contractor, John Furness; signed, Aug. 5; filed, Aug. 13; cost $4558.

Turk and Taylor. Wood mantels, etc; owner, A. W. Wilson; architects, Shea & Shea; contractors, Lowrey & Daly; signed, Aug. 17; cost about $8000.

Twenty-third and Valencia. To build; owners, Carrie L. Dick and W. M. Cowie, trustees; architects, McDougall Bros; contractor, D. Currie; signed, Aug. 19; filed, Aug. 20; cost $2734.

Twenty-third near Noe. Cottage; owner, E. A. Knowles; contractor, Wm. Plant; signed, Aug. 21; filed, Aug. 27; cost $1900.

Twenty-fourth near Castro. Alterations and additions; owner, Catherine Sullivan; architects, Shea & Shea; contractor, Allen De Lair; signed, Aug. 10; filed, Aug. 12; cost $2000.

Twenty-seventh near Church. To build; owner, James Murphy; architect, M. J. Welsh; contractor, V. G. Goodin; signed, July 19; filed, Aug. 25; cost $1155.

Union near Devisadero. To build; owner, John Martinon; architect, N. Blaisdal; contractors, Campbell & Pettus; signed, August 24; filed, August 26; cost $2725.

Union and Marion Place. Alterations and additions; owner Catherine Hatfield; contractor, L. C. Berger; signed, Sept. 3; filed, Sept. 8; cost $1156.

Valley street near San Jose Ave. To build; owner, Daniel Carmody; architect, M. J. Welsh; contractor, R. Fahy; signed, Aug. 30; filed, Sept. 1; cost $2522.

Van Ness Ave, near Green. To build; owner, Jennie Schonwasser; architect, M. J. Lyon; contractors, Hannah Bros; signed, Aug. 14; filed, Aug. 19; cost $4718.

Vermont near Yolo. To build; owner Mr. Balz; contractor, Casper Zwierlein; cost $1700.

Washington and Baker. Excavation and brick work; owner, Clinton Henry Ball; architects, Laver & Mullaney; contractor, H. H. Larsen; signed, Aug. 26; filed, Aug. 27; cost $1380.

Washington and Baker. Carpentry work; owner, Clinton Henry Ball; architect, Laver & Mullany; contractors, R. Weeks and Son; signed, Aug. 26; filed, Aug. 28; cost $8085. Plumbing and gas fitting; contractor, W. F. Wilson; signed, Aug. 25; filed, Aug. 28; cost $1320.

Yerba Buena near Clay. Two-story frame; owner, Daniel Carmody; architect, M. J. Welsh; contractor, Ed. Mooney; signed, Aug. 30; filed, Aug. 31; cost $2450.

PALO ALTO.

Palo Alto. Cottage; owner, M. D. Hall; architects, Cuthbertson & Williams, contractors, Powell & Dean; signed, Aug. 18; cost $1325.

Remittances should be in the form of postal orders, payable to THE CALIFORNIA ARCHITECTURAL PUBLISHING COMPANY, and all communications addressed to the office of the Company, 408 California Street, San Francisco, Cal.

OUR WORTHY Mayor of San Francisco, with the laudable purpose of securing for the government of this city a suitable organic law, appointed some weeks ago a committee of one hundred citizens representing all shades of political opinion, and requested that they prepare or formulate a new charter on progressive lines, in the hopes that a non-partisan board of free-holders could be elected to officially submit the same to the voters of the metropolis, for their acceptance. This committee has been steadily at work on the task, and has outlined a charter which they hope would be approved by the voters and give a better and more economical government for this city than is possible under the existing antiquated and complicated hodge-podge of special enactments that have from time to time during the last thirty or forty years been enacted by the legislature for the government of San Francisco. The committee has proposed many features that are in line with modern ideas of Municipal government, among others the acquisition and control by the city of public utilities. This naturally would arouse the active opposition of the corporations that profit annually to the tune of millions of dollars by conducting these utilities, and there are signs that they have already begun to lay wires to defeat the charter that will be proposed by the committee of one hundred. Bear in mind that the present committee is unofficial, and that the charter as submitted to the voters must be (at least nominally) prepared by the duly elected freeholders chosen for that purpose. It is the intention of the committee to present to the electors a board of free-holders pledged to the support of the instrument now being formulated. Should this plan be allowed to mature without opposition, there is little doubt that the charter would be ratified by the electors, as the need of a proper and definite governing authority is becoming more and more imperative. But this is dealing with the question

and leaving the corporations and politicians out. The politicians and corporations do no wish to be left out however, and it is dollars to doughnuts that they will make themselves felt. Suppose the regular political machines combine forces and nominate a set of free-holders conjointly; they would certainly have a fighting chance to elect their men in opposition to the candidates proposed by the committee of one hundred, and the result would be that the charter submitted by them to the people for the adoption would be no more like the committee's charter than chalk is like cheese. The developments in the game during the next month will be full of interest to all public spirited citizens.

WITH THE death of one woman and the awful experience of many others, the recent terrible explosion and fire at the California Fuse Company's works, has demonstrated very strongly the necessity of Legislation prohibiting completely the use of any kind of light or fire in any building used for the manufacturing or storing of combustibles and explosives. This fire started from an electric lamp, conclusively corroborating what has been said before. There are plenty of hours during the position of the Sun above the horizon for any employe to work, and any building for the purposes stated above can be planned and built so that the Sun's light penetrates to all corners and places. The only explanation that work has to be done by artificial light or that buildings are built so as to need the same during the daytime, must be therefore the infernal greed for pelf which seems to possess almost all humans, and which should be made a criminal offense when endangering others.

WITHOUT arrest and without trial by judge or jury, twenty workingmen were shot to death the other day by order of the Courts of this country for disobedience to a Court decree. But they were poor men, ignorant of the implicit obedience that all good citizens render to the voice of the constituted anthorities. Thus does the MAJESTY OF THE LAW compel the respect of cringing foreigners. By the way! Some years ago the proper authorities of San Francisco ordered several miles of unused railroad track on Bush street to be torn up: the Courts decided that the order was a lawful order and must be obeyed. Yet the rails still rust peacefully on Bush street and none of the recalcitrant directors of the corporation have as yet been shot. It is high time that San Francisco awoke from her slumbers and took a lesson from the more progressive Eastern States, as to the most effective methods of compelling respect and obedience to the mandates of the Courts. It is really disgraceful that this city should be so much behind the times, and we sincerely trust our sheriff will at once take the necessary steps to secure the number of rifles and gattling guns that may be necessary to place us on an equality with our sister cities, that our citizens may hold their heads erect, proud in the consciousness that San Francisco is no longer a jay town.

IT AFFORDS us considerable satisfaction that verdicts have been given by Juries in at least two recent cases in San Francisco, in favor of architects as against clients. The decision in these cases indicates that in the opinion of the Jury the client desired and tried to effect the robbery of the architect he employed. The opinion of a large class of the building public that an architect is a safe man to mulct is still very rife, and we hope the eminently just decision of the jury in the two cases referred to will serve to make people think twice before attempting to get something for nothing; another name for robbery.

In the first case Laver & Mullany *vs.* Hotaling—the defendant had used the time, labor and talent of the plaintiff in obtaining means by which he could judge of his ability in getting an income out of certain property and offered some petty sum for the experience and advice offered him. When the defendant goes to a physician or lawyer for advice he expects to be called upon to pay a good fee for it, but the plaintiff being only an architect with no organization to back him, he was considered safe prey—the jury luckily thought otherwise.

In the last case that of Deprosse & Meusdorffer *vs.* The Eagle Distilleries the attempt at thievery was just as palpable. The defendant had made working drawings and partly superintended the building, when they were dismissed and payment for their services refused. The Jury evidently could find nothing in the evidence showing why they should not be paid the value of their services and decided accordingly.

We would advise architects in the future to have jury trials, as a body of twelve ordinary men are not swayed by legal quibbles and technicalities as we generally find to be the case when a matter is tried by a judge, as some architects have found to their cost, but look at the honest rights of a case, and when they see an attempt at squirming out of paying for things clients order, give verdicts accordingly.

If the architects had a protective association like all other businesses, giving mutual help and protection against the unconscionable conduct of those who sneak around to get their labor and brains for nothing—such things would not be so ready to attempt it.

PROSPECTUS FOR THE PHEBE HEARST ARCHITECTURAL PLAN OF THE UNIVERSITY OF CALIFORNIA, BERKELEY, CAL.

THE UNIVERSITY OF CALIFORNIA has undertaken an enterprise which it is hoped to make one of the most notable in the history of architecture; and in this hope it asks, through the wise and loving kindness of Mrs. Phebe A. Hearst, the co-operation of the architects and artists of every land and clime, in the preparation of a plan for an ideal home of education.

The purpose is to secure a plan to which all the buildings

that may be needed by the University in its future shall conform. All the buildings that have been constructed up to the present time are to be ignored, and the grounds grounds are to be treated as a blank space, to be filled with a single beautiful and harmonious picture as a painter fills his canvas.

The University of California was founded under an Act of the Congress of the United States, passed in 1862. It received a large land-grant and subsidies, and still receives, in addition, a yearly income from the United States. The Charter of the University was granted to it by the State of California, in 1868, and a part of its income is derived from a tax of two cents on each $100 of the taxable wealth of the State, which income is, of course, constantly increasing in amount.

It will thus be seen that the University has both a National and State character. Its present resources are valued at about nine million dollars and, in addition to the revenue derived from part of such resources, it has a yearly income of about $40,000 from the United States, and of about $250,000 from the State tax. The University has trebled its number of students in six years. It has 777 in 1891: it has 2300 now, and it will probably have 5000 after ten years, which is the number of students for whom the architectural plan should be calculated.

The site of the University of California, at Berkeley, California, comprises two hundred and forty-five (245) acres of land, rising at first in a gentle and then in a bolder slope from a height of about two hundred feet above the sea level to one of over nine hundred feet. It thus covers a range of more than seven hundred feet in altitude, while back of it the chain of hills continues to rise a thousand feet higher.

It has a superb outlook over the Bay and City of San Francisco, over the neighboring plains and mountains, and the ocean. It is the desire of those who have charge of this enterprise, to treat the grounds and buildings together, landscape gardening and architecture forming one composition, which will never need to be structurally changed in all the future history of the University. It is thought that the advantages of the site, whose bold slope will enable the entire mass of buildings to be taken in at a single *coup d' oeil*, will permit the production of an effect unique in the world, and that the architect who can seize the opportunity it offers, will immortalize himself.

It is seldom in any age that an artist has had a chance to express his thought so freely, on so large a scale, and with such entire exemption from the influence of discordant surroundings. Here there will be at least twenty-eight buildings, all mutually related and, at the same time, entirely cut off from anything that could mar the effect of the picture. In fact, it is a city that is to be created,—a City of Learning,—in which there is to be no sordid or inharmonious feature. There are to be no definite limitations of cost, materials, or style. All is to be left to the unfettered discretion of the designer. He is asked to record his conception of an ideal home for a University, assuming time and resources to be unlimited. He is to plan for centuries to come. There will doubtless be developments of science in the future that will impose new duties on the University, and require alterations in the detailed arrangement of its buildings, but it is believed to be possible to secure a comprehensive plan so in harmony with the universal principles of architectural art, that there will be no more necessity of remodeling its broad outlines a thousand years hence, than there would be of remodeling the Parthenon, had it come down to us complete and uninjured.

In the great works of antiquity, the designer came first, and it was the business of the financier to find the money to carry out his plans. In the new building scheme of the University of California, it is the intention to restore the artist and the art idea to their old pre-eminence. The architect will simply design, others must provide the cost.

About five million dollars have already been pledged for a beginning, and such a general desire to contribute has been manifested, that it is thought that all the funds required will be forthcoming as fast as the work can be carried on.

Mrs. Phebe A. Hearst, widow of the late United States Senator George Hearst, and a lady well know for her philanthropy and public spirit, and her interest in and taste for all things artistic, has provided ample funds for securing the architectural plan. For this purpose she has appointed a Board of Trustees consisting of the Governor of the State, James H. Budd, representing the State; one of the Regents of the University, J. B. Reinstein, representing the Board of Regents, and one of the Professors of the Faculty, William Carey Jones, representing the University.

While the method of obtaining the architectural plan has not been decided on in detail, it is thought that it will be done by an international *concours*, open to all the architects of the world, with an international jury of five members, who will have full charge of the *concours* and of the award of all the prizes. This *concours*, while partaking in some degree of the nature of the usual competition, will possess all the main features of an actual co-operation of the best architectural and artistic talent available for the purpose, as will be seen from the programme which has been prepared with that idea as a controlling one.

There will be two competitions, and ample prizes will be provided. Maps, casts and photographs of the gronnd will be placed at various accessible points in Europe and America, for the convenience of architects desiring to enter the *concours*, and the programme thereof, prepared by Professor Guadet, of the School of Fine Arts of France, is now under consideration by the Trustees, and it is hoped to distribute the same within the next sixty days.

Copies of this programme, when issued, may be obtained by architects from the various architectural societies in America and Europe, or upon application to the Board of Trustees, at their office, 217 Sansome street, San Francisco, California.

The University of California is destined in no long time to be one of the great seats of learning of the world, and the architect who plans for it a home worthy of its future, and of what a famous authority has called "the most beautiful site on earth for the purposes of a University," will make his name imperishable.

San Francisco, California,
August 31, 1897.

ALTERATIONS.

PERHAPS the most troublesome and vexatious of the duties of the architect is that of planning and supervising the alterations of old buildings and premises. We have heard many architects say that they would rather have to do with two new houses than to alter one. In the preparation of designs for a new building, the whole is plain sailing. The requirements understood, the plan and elevations made, the architect has to execute them. There is the site, free and unencumbered by any other buildings, there are no heights and levels to arrange; but, both in area and vertical dimension, there is an unrestricted field for the carrying out of the design which has been previously worked out to scale in plans and sections. The artist feels, too, that he has a *carte blanche* to do what he pleases; he has the instructions and a free scope for his talents without limit. Like the painter with a clear canvas, or the sculptor with a block of marble, he is master of the situation, and can use his own discretion in making the best of his opportunities.

There are two general kinds of architectural alterations. One is when the existing building or premises has to be altered internally or be remodeled; the other when a new portion has to be added, and the parts simply connected without any interference with the older part. More correctly, the latter is an addition. When a partition is erected to divide one into two rooms, or a passage has to be thrown into a room, a staircase altered, we have an alteration coming within the first class. A new wing to an old house, a bay window, a chancel or transept to an old church, or the erection of a spire, all come within the second class of alteration. We all know which of these two classes of work the architect would sooner have to deal with. Take a badly arranged or an old, dilapidated house: several internal alterations are necessary to be made to it: a plan and specification are prepared, and tenders are invited. The first difficulty of those who tender is to know exactly what has to be done. Men of little experience guess at the amount: those of long experience in alterations hesitate—they are careful to make a personal examination before committing themselves to price. Where to stop? How will this wall or that floor or roof bear cutting into or patching? What are the risks and contingencies to be incurred?—these are the sort of questions which arise in the mind of the cautious builder before signing a contract for alterations. A wide margin is the only safeguard, for every one conversant with building alterations knows the utter impossibility of discovering beforehand what a certain alteration will entail, or what lead to, by the time the work is finished. The record of specifications for this class of work and actual experience, as furnished by practical builders, will remove any doubt in the mind of those who think that alterations and building are to be regarded in the same light. Take, for example, an old floor. A partition below it has to be removed to make a room larger. The architect specifies for the shoring up of the floor and ceiling, and the insertion of a beam or rolled girder to carry the ends of joists of the old floor. Actual experience discovers that the plan is impracticable. The joists are found to be too decayed at the ends to be reused; or, what is more probable, the binding-joists are quite incapable of doing duty after they have been disturbed by the operations. Instead of a few new joists or a single girder, the work entails a new floor. Even greater risks attend the alteration or raising of an old roof. The timbers, which might have lasted for years if undisturbed, quickly crumble and the joints of the framing are found to be rotten. Old leadwork is the same; often it will not bear disturbance, such as would be the case in the raising of a flat. Between patching and thoroughly making good the difference is exceedingly great, and there is a strong temptation among small builders on this account to evade the terms of the specification. To remove the old timber or lead and to credit the value of the materials is no easy matter.

Allowance for old timber that may turn out to be rotten is almost impossible. Restorations or repairs are generally involved in contracts for alteration; and in these works credits make a considerable item in the bill. Thus, we constantly find in specifications for alteration the phrase "remove and credit" when the extent of removal may be uncertain, and the condition of materials still more so. In church restoration the difficulties are often great. Thus we find such an item as the following, "Remove roof of aisle, comprising two bays, and make good work disturbed." This may involve the removal of a few squares of boarding, roof-timbers, and lead. Unless the exact quantity of lead is stated the item is a very doubtful one. It is hardly necessary to urge the importance of giving the quantities of the old materials and their position in the building. With regard to such material as lead, it is better to measure the same as it is removed, the contractor stating in his tender how much per cwt. he will allow for it. Much difficulty, however, is avoided when the old materials are sold at the onset, which can only be done when the building is pulled down. But, whichever mode be adopted, there is an element of uncertainty and doubt in tendering for work of this description—one which can only be reduced by a careful and analytical examination of the building before the prices are affixed. As we occasionally find, there is a great difference in work of this kind under architects. One will enforce the terms of the specification, another will allow of a loose interpretation. Hence work executed from the same specification under one man's supervision may cost 50 per cent more or less than under another. For instance, what a divergence of opinion will be found among builders in such matters as cutting out to insert new windows, or in repairs to stonework. In the repair of an east window, which included cutting out decayed stones, inserting new, and the removal of saddle bars and glass, one tender was £10, and another nearly £30: but instances may be multiplied proving the various interpretations placed by builders upon items. Nor can such divergencies be materially lessened by the ordinary methods of practice; the good sense, moderation, and judgment of the architect, and the careful examination of the contractor, are the only means of diminishing the contingencies. In bills of quantities and specifications for alterations, more accurate results would be arrived at by a preamble describing clearly what was intended to be accomplished, so that those who tender may understand the motives and objects of the architect and client, instead of being compeled to grope in the dark, and to find out how best they can meet the liabilities that they will have to incur in the execution of the work. Instead of clearness, vague descriptions are given, and the aim appears rather to throw the interpretation upon the contractor.

But the architect's difficulties do not end with the specification. In the first place, he is tied to existing conditions. He is restricted to certain levels and to a certain style. Structural difficulties are also great, and then when he has done his best the work is unsatisfactory. It is only a compromise after all. Such in brief is the experience of those who have had much to do with alterations of old houses of inferior type. The desire to do what is best and right is constantly interrupted by some existing circumstances, so that very little can be done thoroughly. But the chief troubles commence when the work is begun. Unexpected things are discovered directly the old work is touched, and these often render a different method of procedure necessary. An order for extra work is generally the consequence, needing an incessant attention to details which have perhaps never been thought of before. Much of the trouble and anxiety which interfere with the architect's peace of mind arises from inaccuracies in the drawings, which sometimes are found to disagree with the old work. However careful the dimensions may have been taken, discrepancies will occur; and it may perhaps be worth while to remark that if in such cases architects in furnishing drawings were not to figure dimensions, such as heights, but to direct on the drawings that these are to be taken by the contractor from the actual building before commencing the work, a good d of risk and labor would be saved. We have known of s ta cases being made to agree with a section, which, turning out to be inaccurate in the levels as figured, have had to be altered. Sometimes an additional window has had to be added, much to the detriment of the staircase. But the increased labor and trouble entailed is not estimated by the employer.

It is seldom architects charge more than the customary percentage for alterations, which is miserably inadequate as a remuneration. The drawings may be few—and correct plans and elevations are the chief requirements—but a very full and complete specification is absolutely essential, requiring a close and accurate survey of every part of the structure. In short, the proper plan is to write the specification, or to make notes for it in the building itself, so that no point or detail may escape notice. Quantities for such work can be only accurately prepared from a personal inspection. The greatest task of all is the supervision of alterations. To meet contingencies and difficulties when they appear, and to be able to cope with them, is a trying ordeal for the young practitioner. So much depends upon discovery in the progress of pulling down or removal, that nothing less than a vigilant inspection and watchfulness on the part of the clerk of works or the architect will be of much good. To be forewarned is to be forearmed, and to be able to apply an alternative method to any problem is one of the tests of the resources of the architect. Yet a great deal of uncertainty as well as anxiety might be spared if architects and builders intrusted with alterations were to be permitted to make experimental examinations before plans or estimates were prepared. Superficial surveys, such as making plans, are quite inadequate to discover hidden construction or the actual condition of materials. These ought in all instances to be supplemented by examinations of those parts which are affected by the proposed alterations.—*The Building News.*

WHILE repairing the Heidelberg Castle ruins some workmen found a window group, the style revealed the fact that the castle was not begun in 1411 but about 200 years earlier

EGYPTIAN MONUMENTS.

UPON looking at the monuments of ancient Egypt anterior to the eighteenth dynasty we find two great groups belonging to distinct ages, which are in a certain measure connected, but certainly not linked together by other minor groups which can be proved to stand between them. The first of these groups is that of the pyramids of Gizeh and of the tombs surrounding them. These are unquestionably the oldest monuments of Egypt, and probably of the world. Their massive architecture, which wears an air of primæval antiquity, the similarity of their form to primitive structures in various part of the world, and the archaic style of the sculptures of the tombs, alike prove their remote age. The subjects of the sculptures also differ greatly from those of later Egyptian art. One of the most striking and remarkable distinctions is the absence of representations of divinities and funeral rites, which are constantly found in tombs of a later period. The manners and customs belong to a primitive age. Laboring men are usually represented naked, which is not usual in other monuments; the chief occupations are connected with agriculture and the tending of cattle, and there is no trace of an army. The language appears in a more primitive form, and the inscriptions, which are for the most part merely descriptive of the sculptures, are very difficult to read.—The secsnd important group of monuments bears the names of kings of Manetho's twelfth dynasty. They consist of a small temple, remains of other temples, tombs, obelisks and statues. The architecture is very different from that of the Pyramids, being less massive and more elegant. The sculptures, though still resembling in style those of an earlier date, exhibit a considerable advance. Separate statues have a better form and superior finish. The animals are admirably represented. There is still an absence of religious representations in the tombs, but divinities are portrayed upon other monuments. The subjects are of a less simple character than previously. The arts appear to have been more advanced, and life to have been more refined and luxurious. Soldiers are represented, and the laborers are usually clothed. The language is more developed, and perhaps may be considered to have reached its perfect state. Such is the impression which an intelligent observer would receive upon examining the monuments on the spot. He could have no doubt of the relative age of the two groups, but he would find no means of determining the period of time which intervened between them. He could see that no one in Egypt could possibly confound two such different epochs, and that therefore the priests would place, as a matter of course, the kings of the first group in an earlier dynasty than those of the second group. So far Manetho's account is confirmed by the monuments, but further than this we cannot venture to go before the eighteenth dynasty. Our real knowledge of the most ancient history of Egypt is almost entirely confined to the Pyramids and their builders.—*The Architect.*

TESSERÆ.

DETAIL IN PAINTING.

THE contempt expressed for paintings of fruit, flowers, and what is called still life, is, like most other general and unqualified expressions of the kind, unjust; for though it be true that an artist may be able to paint such things

well without possessing sdill in any of the higher branches of the art, the converse is not so, no artist having been able to paint great things well who could not also paint little things. In the grandest and most perfect production of the pencil, the *Peter Martyr* of Titian, all the trailing plants, spreading leaves and flowers which decorate the foreground are painted from nature, with all the accurate truth of a botanist, though with all the light, airy, playful brilliancy and harmony of effect of a great master. We are aware, indeed, that Sir Joshua Reynolds has hastily denied the fact, and the merit of it if it were so; but the picture, though injured, is still exisiing to attest it; and if significant and entertaining objects can be employed in such decorations, common sense proclaims them to be preferable to unmeaning blots and random flourishes, which, like all other ornaments

yin g nothing, have an offensive character of obtrusive affectation. Hence, so far from despising skilful and elegant imitations of such objects, all the great masters of the art have studiously practised and successfully employed them; and, in proportion to their general excellence in the whole, has been their particular excellence in these subordinate parts. The leaves, fruits and flowers of Titian and Rubens are far superior to those of any professed and exclusive painter of such subjects, and their vases, phials and implements to those of any other artist whatsoever. Even the patriarchs of the truly grand and severe style, the founders of the Roman and the Bolognese schools, found it expedient to pay no less attention to these matters of decoration as the fruit in a picture of Ludovico Caracci, in the Earl of Ashburnham's collection, and the writing-desk, inkstand, books and hour-glass in a portrait of Cardinal Ribbiena by Raphael, publicly exhibited some years in London, may sufficiently evince. Teniers might have envied the fidelity, delicacy and transparency with which the latter are finished. Neither did Salvator Rosa, the most bold, negligent and sketchy of the great painters, think it beneath him to attend to such matters, as appears by the admirable truth, force and brilliancy with which the weathered leaves, tattered volumes and bones of fishes and animals are finished in his picture of Democritus.

COLOR IN THE ARTS.

The thing in the sense of art called "color" is never absolute in itself, but derives its value, like the varying lots of human life, from comparison with what is next and around it. The same tint will be bright or dull, according to its environments. As a rull, no color in a fine work will be found so bright as it looks, and inversely, no color in bad or oadinary work will look so bright as it is. A tawny sail oh a gray sea and sky by Ruysdael will shine like a ruby, wnile all the reds, blues and yellows, indiscriminately shuffled together, as in some of the painted glass of the present day, will fail to produce the effect of brilliancy, and, indeed, each of them will destroy its neighbor. In this principle of interdependence in the scale of his palette the true painter becomes more and more conscious, his chief art being to work it out in practice. But no similar consciousness can be attributed to unreasoning races. Therefore, for such evidences of the prevalence of fine color as are found among them, a different operation of the same principle must be sought. In countries where there is much light we shall invariably find rich and harmonious coloring in the costumes of men and the trappings of animals. Much light bleaches the landscape, and for the greater part of the year, and, in some localities, for the year round, the eye rests only on an arid and neutral-colored world. This monotony renders all color, as such, both precious and nistinct. Nature sets the example by the brilliant plumage of her birds, and the hues of smaller creatures—a brilliancy never raw or crude; and nature derself gives the materials as well as the example for the same harmonies in the accessories of human life. Eastern races have for ages been aware that only the rich and true colors supplied by their native dyes—the madders, indigos, etc.,—and their combinations, will stand the hot and nazzling conditions of their climate. The use of these colors has therefore become such a mere habit that the reasons for their preference may be said to be forgotten. The selection of the fittest has been made for them by nature herself; it being reserved for the Englishwoman in India, who ignores this law, to discover with dismay the dirty mixture to which her fresh Parisian dress in the last tint of the fashion is promptly reduced. Even in their fadings the dyes of India and Arabia—aided by the quality of the native wools, which have an affinity for them—maintain their relative harmonies; and the painter will often prefer the worn rug or robe to the new one. Nor must we overlook another another reason for rickness and depth of tone, equally independent of the taste of man: namely, the use of color as an ingredient of distinctness. Seen from afar, across the neutral mass of the ocean, the brilliant hues of the ship's flag or pennon are no matter of mere taste or fancy, but of necessity. In the same way the robe and the turban of the traveler in the desert, and the housings of his horse or camel, have their allotted purpose. Thus it happens that the harmonious combinations of the Persian carpet or Indian shawl are hardly to be credited so much to the "feeling for color" of the native weaver as to the light and heat which render all false tints fugitive and which these combinations alone resist; the providence of nature having also bestowed materials in which he can hardly go amiss. Not that we would deny to the Eastern weaver, who in such countries offers the only approach to the position of a painter, the exercise of taste, and that sometimes of a high kind, the result of culture of the eye under long-continued traditional arrangements; but he moves and works, to a great extent, in a groove formed for centuries before him. To turn now to our own land, where, far from having the light and heat and consequent neutral monotony of landscape to which we have endeavored to trace the use of the rich coloring of the East, our native landscape presents, more or less, all the year round, a mass of that color most foreign to the Oriental eye and most grateful to our own, namely, that of a soft and refreshing verdure. We sigh not nothing better, nor for more harmonious correlative than the time-worn hues of stone or brick—the gray church tower and the old brick mansion—the neutral yellows and grays of the cornfield, whether in ear or stubble, and the ever-changing varieties of gray and luminous cloud, all of which receive a relative value from the surrounding green. Other forms of so-called "color," such as masses of sparkling mosaic, patches of enamel, painted architecture, even precious marbles, are not what the prevalent tones of English landscape and sky really relieve. The lady's Indian shawl is known to be the true and choice thing by a limited jury, but, in her heart, the lady's maid thinks it a dull afair to have cost so much. For we have not light, and therefore neutral tint enough to set it off. That under these differing and even unfavoring conditions English art, from the period of its revival, should have been pre-eminent in the quality of "color," may be

said to be in some degree also the natural consequence of our external world. Dingy cities and gloomy skies engender the desire for mimic scenes of greater brightness. It is characteristic that modern Italian painters frequently choose those misty effects they seldom see—we have too much of them.—*The Architect.*

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

CITY FLATS, Oliver Everett, Architect.

AN OLD SWITCHBACK RAILWAY.

THE switchback railway, which has become so popular of late years, is a very old invention, and was a favorite recreation of the Parisians in the beginning of this century. An entertainment garden on much the same lines as Cremorne was opened by a manager named Beaujon. It was situated in the suburbs of Paris, and cost its projector one million and a half of francs, for he had raised the ground till it formed a hill as high as the Vendome column, and on this he built his switchback. It was a peculiarly arranged edifice of two semi-circular flights, commencing at the entrance to the arena. From this point they rose, each with an undulating sweep, to the elevation of a hundred feet, and united under a turret, thus forming on each side a slope of seven hundred feet in length.

The wheels of the car ran in a double groove. The passengers entered it at the turret, and it was launched on the inclined rails, down which it swept till it reached the bottom. It was then drawn by peculiar mechanism up the straight track in the centre till, arrived at the turret once more, it had carried the voyager over a thousand feet in one minute. The turret was surmounted by a lighthouse, which had been made for the port of Toulon, but the enterprising Beaujon secured it as a decoy light to his beautiful garden. At first it was called "Beaujon's Folly," but the magnificence and elegance of the place ultimately earned for it an established success as the most luxurious and fashionable resort in Paris.

NOTES AND COMMENTS

AN ARCHITECT AND BUILDER who was very proud of his efforts in designing a house which he had just planned and built met a well known architect in front of the said house. The architect and builder could not resist the impulse to show the architect his creation—and asked him to step in and have a look round and tell him what he thought of his effort. This happened only just lately and the architect had nothing to do that morning so he obliged the architect and builder by viewing his house. "Well, what do you think of it, pretty good isn't it?" said the A & B—when they had got outside and were looking up at the jig sawed front. "Yes," said the architect, but it seems to me you have got too many rooms." "How can that be?" replied the A & B, "there is the parlor, dining room, kitchen and three bed rooms—I can't for the life of me see where any of these could be left out." "How about that large room for improvement?" said the architect, leaving the A & B scratching his head and trying to locate that room.

LONDON IS SOON to be the richer by another hospital, the members of the Architectural association finding yesterday on a visit to the New Grove Fever hospital of the Metropolitan Asylums Board, that the place was fast nearing completion. The hospital is intended for cases of scarlet fever, enteric fever, diphtheria, and general fever cases. It occupies a site of some 27 acres, and there are 36 blocks. There will be accommodation for 518 patients and 324 persons connected with the medical, administrative, domestics, and nursing staffs.

BASLE, SWITZERLAND, will celebrate the 400th anniversary of Hans Holbein's birth by an exhibition of his paintings and drawings, to which other Swiss museums will contribute what pictures of his they possess. Solothurn cannot send its Madonna, as the risk is too great. The exhibition will be opened early this month and will last through the winter. It will be preceded by an exhibition of the works of Arnold Boecklin, who is a native of Basle and this fall is seventy years of age.

BOOKS AND PERIODICALS.

AMERICAN TRADE is the title of a small paper which is published by the National Association of Manufacturers, at No. 1751 North Fourth street, Philadelphia, Pa. The first issue bears the date of October 1st, and it is announced that it will appear on the first and fifteenth of each month. The purposes of the paper are thus editorially explained in the first issue:

"The publication of a small newspaper has been undertaken by the National Association of Manufacturers of the United States in pursuance of recommendations made by the Executive Committee over a year ago. This little paper is started with no journalistic pretense and with no ambitions save the promotion of the interests of the Association, and, through this organization, the welfare of the industries of the United States. Its establishment is due, also, to the need for some frequent and convenient medium of communication between the members of the Association, who now number more than 1,000.

American Trade has been chosen as a title for this publication because these two words embrace all that comes within the scope of the work of the National Association of Manufacturers and all that the paper itself aims to promote. Whatever the manufacturers of the United States are striving to do in a business way—either individually or collectively in their various organizations—looks to a single end—the promotion of American trade. The enactment of better laws bearing upon American manufacturing interests, the betterment of conditions in the home market, the broader opening of foreign markets for American products, the negotiation of treaties of commercial reciprocity, the establishment of a federal Department of Commerce and Industry, the better protection of patent rights, the restoration of American shipping, and the numerous other branches of public work in which the manufacturers of the United States have an interest.

Journal of the WESTERN SOCIETY OF ENGINEERS August, 1897, gives the Papers, Descriptions, Abstracts and Proceedings of that Society.

Among other articles of interest to the engineer "Limestone Screenings in Cement Mortar" by Arthur N. Talbot, is fully explained and the result of his experiments is given in favor of its use.

"Internal Hydrostatic Pressure in Masonry" as related to the building of dams called forth some description of interest.

We are indebted to J. F. O. Comstock, Superintendent of the UNDERWRITERS' FIRE PATROL of San Francisco, Cal., for the Twenty-second Annual Report for the year ending December 31, 1896. Mr. Comstock recommends if it is possible in the near future that the Patrol Force be increased to twelve permanent and six auxiliary men, including officers.

The directors of the Fire Patrol state that as heretofore the San Francisco Fire Department and the "Patrol" are pulling together without the slightest impairment of friendly relations, the result be successful co-operation.

Annual Report of the Superintendent Physician of the CITY AND COUNTY HOSPITAL for the fiscal year ending June 30, 1897. Together with the report of the Steward and the estimate of expenses of the Hospital up to June 30, 1898.

This report shows what reckless dishonesty has been common among the contractors, as an illustration of this dishonesty Paul Edwards, Steward of the Hospital says it costs the present Administration $3,795.09 to repair the damage incident to the corrupt expenditure of the $10,923.27, that melted in the hands of the past one and for which there was nothing to show but gaping trenches, disconnected sewers, some kalsomining daubed on a few wards and a few dollars worth of carpenter work.

UNITED STATES DEPARTMENT OF AGRICULTURE, Circular No. 16, Division of Forestry, contains a very interesting article upon the "Age of Trees and of Blazing Determined by Annual Rings—full illustrations are given. The conclusion arrived at by B. E. Fernow, Chief of Division of Forestry is that the age of a tree can be ascertained within perhaps one year with proper equipments, time, and preparatory training. This is interesting as it has been frequently stated that the age of a tree could not be ascertained by the annual rings.

HOW TO BUILD A HOME—The house practical being suggestions as to safety from fire, safety to health, comfort, convenience, durability and economy: by Francis C. Moore. Published by Doubleday & McClure Co., New York. 1897. The price is $1.00.

This book deals thoroughly with the practical building of a house, going into the hundreds of details the amateur builder usually learns about through expensive experience. It contains specimen contracts, specifications and plans, and a study of it will save omissions and extras.

Many authorities among architects, builders and contractors have assisted by advice and suggestions in its preparation. An extract from the preface will give a good idea of the nature of the work:

"One builds a home, as a rule but once in a lifetime. Unless an architect or builder by profession, he is liable to make serious mistakes, and to overlook many things which would conduce to the comfort and safety of himself and family. Even if he be an architect and builder, he will do well not to rely entirely upon his own knowledge, but consult others. While he will be likely to escape oversights in proportion as he has had experience, especially if he has been systematic in preserving notes from time to time of discoveries and details for which the memory cannot be relied upon, it is safe for him to assume that some of his acquaintances, especially if experts, may know some things which he does not."

A good Index which adds so much to the value of any book will be found very complete.

THE RISK OF PREMATURE BURIAL.—The following resolution was unanimously passed at the meeting of the Executive committee of the London Association for the Prevention of Premature Burial:—"That taking into consideration the generally admitted unsatisfactory state of death certification at the present time in this country, it is imperative that the State should appoint special officers for the purpose of granting death certificates, as is the custom in Munich, Heidelberg, Stuttgart, and other places, and that no such certificate should be allowed to be issued until the reality of death has been established by careful examination of the body."

A STEEL FLOATING DOCK.

A STEEL floating dock said to be the largest of its kind in the world was recently launched at Wallsend, England. Its length is 450 feet, with a beam of 109 feet, giving a depth of pontoon to the deck of 11 feet, 9 inches. The dock consists of five pontoons and two walls, the former being connected to the walls by a movable joint. The pontoons, which form one immense dock, are of two types—the terminal or end connections, two in number terminating in points, whilst the inner three are rectangular structures. The lifting power of the dock is set down at 10,000 tons, vessels and ironclads of that weight being raised clear of the water in a remarkably brief space of time, whilst with the aid of two large steel caissons, one under each wall, the lifting power can be increased to upwards of 12,000 tons.

The pumping and other machinery is of the latest and most improved class. The pumps are driven by electric motors placed on the engin deck, and connected to the pumps by vertical shafting, the flyers being slung on improved steel ball bearings. Other motors are placed on the side of each wall. The dock throughout will be lit up with electricity, five large arc lamps being arranged on the inside of each of the dock for for the lighting of the well. Special attention has been given to the docking gear, the principal parts of which consist of two self-centering shears, two patent steam winches, rolling and spring tumblers. The bilge blocks, to the number of forty-six, are all made of steel and portable, being controlled by chains form the upper deck. The comfort of the men employed in the working of the dock when in use has been well provided for, a large steel house, tastefully fitted with teak furnishings, having been placed on each side of the upper deck, with direct connections between all the branches of mechanical work, a separate lever being attached to every pump.

This huge dock is to be towed across the Atlantic to Havana, it having been built for the Spanish Government. —*The Age of Steel.*

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street,
SETH BABSON, Pres. H. A. SCHULTZ, Vice-Pres.
OLIVER EVERETT, Sec. JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.
THEO. A. EISEN, PRES. ARTHUR B. BENTON, Vice-Pres.
WILLIAM C. AIKEN, Sec't. AUGUST WACKERBARTH, Treas.

WASHINGTON CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.
JOS. C. HORNBLOWER, Pres. JAS. G. HILL, Vice-Pres.
E. W. DUNN, JR., Sec. W. J. MARSH, Treas.

ASSOCIATION OF ARCHITECTS OF ARIZONA, meetings held at Phoenix, Arizona.
D. W. MILLARD, Pres. T. H. MADDOX, Vice-Pres.
W. R. NORTON, Sec. and Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.
E. J. MOLERA, Pres. W. F. C. HASSON, Vice-Pres.
OTTO VON GELDERN, Sec. EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.

ADAM BECK, Pres. M. V. BRADY, Sec.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

LIABILITY FOR WORK OF INDEPENDENT CONTRACTOR.—Where persons who took the contract for tearing down a brick building, and constructing a new one, let the brickwork, including the tearing down of the old walls, to a subcontractor, the former were liable to a stranger for injuries caused by a hole in the sidewalk in front

of such building, made and left at night ungarded and unlighted by such subcontractor.

Baumeister v. Markham (Ky.) 39 S. W. Rep. 844.

Building Limit.—Where an ordinance prohibits the erection of buildings of combustible material within certain limits other than such as are provided for the ordinance, the removal of a building constructed of combustile materials from some other portion of the fire limits to another place within such limits is unlawful.

Eureka v. Wilson (Utah) 48 Pacific Rep. 150.

What is not Negligence of Roofer.—The owner of a building, or his contractors, while putting on a gravel roof, is not negligent in failing to clear the sidewalk every hour of gravels which fall on it.

O'Reilly v. Long Island R. Co., 44 N. Y. Supp. Rep. 264.

Credit for Payment to Laborers.—A lot owner who pays money due from the contractor to laborers who are seeking file liens on the property is entitled to credit therefor when sued for the contract price.

Kocher v. Mayberry (Tex.) 39 S. W. Rep. 604.

Contract Price Less Damages.—The measure of recovery is the contract price if the work was properly done, less the damages shown to have been sustained by the owner by reason of delay of contractor.

Orem v. Keeley, (Md.) 36 Atlantic Rep. 1030.

BUSINESS MOSAICS.

W. P. Fuller & Co., Pine and Front streets, San Francisco, are always prepared to furnish you with facts about paint. They claim that the best paint is made of white lead, zinc and linseed oil to make pefect paint these materials must be finely ground and thoroughly mixed with heavy machinery, Phœnix Pure Paint is made in that way which accounts for its good qualities.

But you can obtain facts about other things than paint at their establishment as they can tell you all about the new wall finish, or washable water color that petrifies on the wall and will not crack or chip off.

L. E. Clawson& Co., 1340 Market street, San Francisco, Clawson's Patent Hood or Throat and Arch-Bar Combined is well recommended to those that want the best in this line as it complies with the New Fire Ordinance. Every thing in the way of a safe chimney can be obtained at this establishment.

Biggs—That man Mixer reminds me of a horse. Diggt—In what respect? Biggs—You can lead him to drink but you can't make him take water.—*Chicago New.*

W. H. Wickersham, Building Contractor, at 1128 York street is a man that if you employ him once, you are sure to employ him the next time you want work done in his line—what better recommodation can a man have.

W. D. Hobro plumber and gas-fitter, 728–730 Washington street. San Francisco, has an enduring monument in his favor in the work that has been done in this city. From Richmond to the water front can be found his work that will prove the old saying that "Actions speaks louder than words."

Now that the stormy season is approaching it is a good time to look out for leaks—those who are wise will call at 116 Battery street and order Paraffine Paint or perhaps paint and paper as the case may be.

An ounce of prevention you know is worth a pound of cure—see that your gutters are clear and coated with Paraffine Paint.

Snodgrass—The world has a place for everybody. Micawber—Yes; the only trouble is there's generally somebody else in it.—*Boston Traveller.*

Campbell & Pettus, contractors office, Builders' Exchange, 40 New Montgomery street—a glance at the Building News published in this journal will often show their names as successful bidders on contracts.

Old Gotrox—Am I, with all my millions, too old for you? Miss Mabel—Oh, no. That would be impossible. *Life.*

Sampson Spot Cord is what you want to use on your window sash, 115 Congress street, Boston, Mass., samples sent upon application warrented free from waste and imperfections of braid.

"Have you read 'The Choir Invisible?'" "No, what I want to learn about is 'The Choir Inaudible.'"—*Chicago Record.*

A. Zellerback & Sons.—The up-to-date paper house. In order to "ship when we promise" have put on two special delivery wagons. They are prepared to fill orders, big or little, the same day as received. For Fall announcements, opening cards and circulars, with full line of Bristols and Art Papers, including the Strathmore Deckle Edge.

To those who deal with this concern it is needless to say how prompt and reliable it is. To others our advice is to give them a trial look at their warehouses filled with paper at 416–418–420–422 Sansome street, 419–421–423 Clay street as well as 418–420 Commercial street and where all the paper can be consumed.

Kodak—I succeeded in developing a splendid negative in a strong light yesterday. Lens—How did you manage it? Kodak—Asked Miss Richleigh to marry me.—*Chicago News.*

Our attention has been called to a new idea in the joist hanger line. This hanger is made of forged steel and in all sizes so that when a high joist is used the hanger is correspondingly high and as a result the full strength of the header is retained. Architects and owners can appreciate the importance of this manner of supporting a joist. The hanger referred to is The Van Dorn and is for sale by C. J. Waterhouse, 35 New Montgomery street, San Francisco. He has all sizes in stock.

M. S. James, room 27 Flood Building, San Francisco, is the Pacific Coast representative of the J. L. Mott Iron Works, established in 1828, in New York. We take pleasure calling attention to their new advertisement in this number of our journal. It will be seen that Renaissance Design is now coming into fashion both for bath room interior as well as for lavatory and water closet.

Parties are especially invited to call at their show room, No. 27 Flood Building, where the sanitary specialties can be seen. Circulars upon application.

Found in an album: "Visitors invariably give pleasure—if not when they arrive, then when they leave."—*Figaro.*

Smith & Young, 723 Market stseet, San Francisco, 230½ S. Spring street, Los Angeles, Cal., have a stock of almost everything the builder requires, from foundation to exterior finish. See their aduertisement on page ix of this journal as space will not allow us to give details.

"Mabel, is it a fact that you serve refreshments to all the young men who call on you?" "Well, you must think I have money to burn, feeding flames that way."—*Detroit Journal.*

Attention is called to the advertisement of C. J. Waterhouse in this journal—representing such well known firms as Sam'l Cabot of Boston, The Van Dorn Iron Works Co. of Cleveland and The N. & G. Taylor Co. of Phila. Mr. Waterhouse can be depended on to give the best goods for the least money. In addition to the goods he has in stock—he sells from the east the "Pancoast Ventilator" and roofing slates. Call and see him and get circulars and prices of all goods.

VOLUME XVIII. NOVEM 20th, 1897. NUMBER 11.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

A SPECIAL Election will be held in the City and County of San Francisco on the twenty-seventh of December for the election of a Board of fifteen freeholders who will be charged with the duty of framing a New Charter for the future government of the City and County, which will go into effect after ratification by the voters of the City and approval by the legislature of the State. Probably little interest will be taken by the average voter in this election, though as principles and not men are concerned, it is really of more vital importance than the usual run of general elections. The Republican and Democratic parties are so sure of their following that they do not even take the trouble to outline the general principles of government that will be advocated by their candidates. The Populist party has made the following statement of principles:

"The People's party is, by organization and principle, opposed to centralization of power in the hands of a Mayor. City Charters granting such power have in practice proved the source of bossism and corruption in its worst forms in the City of New York and in other Cities which have such Charters.

"We favor good sanitary conditions, improved sewers, streets and public places, and such Charter provisions as will enable the people to secure public utilities.

"We favor localiself-government by a Charter wherein the powers shall be so blended between representation and direct legislation that it shall be truly a government of, by and for the people. We favor also maintaining the control of the people over the affairs of the City."

The Socialist Labor Party has adopted a platform containing the following demands:

I. The board of Supervisors to be a large body, to whom shall be given full executive powers. They shall be

elected according to the principle of Proportional Representation from the city at large.

II. The veto power of the Mayor to be abolished, and direct veto by the people (sometimes called the Referendum) be substituted therefor.

III. The people to have the right to initiate legislation by petition.

IV. The acquisition by the municipality at the earliest possible date, of all public utilities now carried on under franchises; the employees to operate the same co-operatively under control of the municipal administration, and to elect their own superior officers, but no employee shall be discharged for political reasons.

V. The board of supervisors to be prohibited from extending any existing franchise or granting any new franchise without the approval of the people, expressed at a general or special election.

VI. The profits arising from the conduct of public utilities by the municipality to be used for the following purposes:

First—The establishing of a fund for pensioning sick, aged, or disabled employees and other citizens.

Second—The enlarging and extension of the service as required by the growth of the city.

Third—The increase of the compensation of the employees.

VII. The abolition of the contract system on public works, and the substitution therefor of the direct employment of labor by the municipality. Eight hours to constitute the maximum day's labor, and two dollars per day the minimum pay.

VIII. The establishment of public halls and public parks, where public meetings may be held without expense to the participants.

IX. The abolition of the license tax on any business, industry, or occupation.

X. School book, as a necessary part of the educational system, free, and free meals to be furnished all school children. Clothing to be furnished free upon application.

Besides the candidates of the regular political parties, the Charter Convention of one hundred, an unofficial body appointed by Mayor Phelan, will have a set of candidates who will support the general policy outlined in the work of the Convention now being carried on. As the Convention has not yet completed its labors it is too soon to comment on its work. Civil service in the administration of the Municipality will be insisted on as of great importance.

REPORT ON THE CLASSES IN ARCHITECTURE.

CONDUCTED UNDER THE AUSPICES OF THE SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS.

To the Members of the San Francisco Chapter A. I. A.

GENTLEMEN:—Having been requested by the President to make a statement as to the origin, progress and present condition of the classes in architecture, now connected with the Hopkins' Institute of Art and usually designated in our proceedings, the Chapter Classes—I beg to make the following report:

In the year 1870–71, shortly after the establishment of the San Francisco Chapter of the A. I. A. in connection with the parent society, in accordance with a suggestion made in the inaugural address of Mr. John Wright, President on that occassion, measures were taken to establish a school of architecture in connection with the Chapter for the benefit of the articled pupils, draughtsmen and assistants, of the members thereof.

The first regular class as formed were in free hand drawing and practical architecture, modelling and mathematics; the students meeting in the afternoon of Saturday and during week evenings in the offices or studios of some of the teachers, volunteers as teachers for the above departments having been found. Wood carving was also to be included in the list of studies but was never really carried into effect. Ultimately modelling and mathematics were dropped, and finally the classes in practical architecture were also abandoned—the free hand drawing along surviving. Much good work was done, however, under all the different departments and it seemed to be purely adventitious causes which led to their cessation—mostly on account of the irregular nature of the efforts made and the want of proper rooms for the use of the school.

Ultimately however a strong movement arose amongst the draughtsmen in the several architects' offices in the City, having the Chapter Class for a nucleus. The practical architecture was reviewed—and for a time the movement seemed to promise success. A sketch club was formed and several competitions were arranged and much fine work resulted amongst the higher class draughtsmen in the City. The Chapter appointed committees of award—and several money prizes, books, and on one occasion medals of bronze and silver were dispensed to the successful students. On many occasions the walls of the Chapter room blossomed forth in lines, tints and touches of great beauty and fine execution. The association however of the high class draughtsmen of experience with the articled pupils of little or none failed to produce the efforts looked for. The former finally separated themselves from the students taking with them some of the most competent of the latter class—forming an organization of their own—and the Chapter Classes soon resumed their former status and practice which seemed to better meet their needs and aspirations.

During the year 1893—Mr. Alfred Colin, graduate of the Ecole Polytechnique of the Department of the Marine, France, offered his services to the class as teacher of free hand drawing, which were accepted and much good work was accomplished under his directions.

About this time, however, owing to the donation of the Hopkins' house to the University of California, for the use of the San Francisco Art Association—an arrangement was affected with the latter whereby, at a reduced rate, the students were admitted to the privileges of the associations together with the use of appartmenis in the mansion—and thereby became a subordinate part of the Mark Hopkins' Institute of Art, (and practically an affiliated branch of the Art Department of the University) securing at the same time the services of Mr. W. B. Mabeck, an instructor in department, who was made Director of the school.

As to the classes in particular, in connection with the above result, and actually leading to it; in the early part of 1895, a strong movement was inaugurated by one or two energetic students of the school, amongst the pupils and draughtsmen of the various city offices, this eventuated in several meetings at the Hopkins' house, one of which was addressed by several of the professors of the University, and others, and finally resulted in the election of a Committee of Directors and the establishment of classes as above mentioned under the direction of Mr. Maybeck, who became instructor in practical architecture and design.

In this class the pupils are exercised in the study of elemental forms and proportions, being led to determine for themselves the possibilities of each subject of design assigned for consideration. The progress of the class under this system has been eminently successful, much good work has been accomplished, and the students become to a large extent their own and each others critics.

The class in construction was undertaken by Mr. Percy (of the firm of Percy & Hamilton), who lectures the class on the nature and use of Materials in Building Construction once a month—supplemented by the weekly technical instruction of Mr. Dutton, of the School of Technology, Boston, one of his able assistants.

The class in history under the writer of this report, finds with satisfaction that it has been following unwittingly the general course or method adopted by Professor Ware of Columbia College—viz: a system of progressive studies of the development of architecture from prehistoric times to the present day. The students make their own investigations from such works as they find in libraries or private collections—in fields mapped out by the teacher, supplemented by drawings and lectures when necessary; and finally summing up the whole in essays accompanied by text illustrations and drawings of their own. Essays on prehistoric architecture, Egyphian, Babylonian and Assyrian architecture have been received so far some of them of much general excellence.

These essays are examined by the Committee of Directors, and awards of merits tabulated, and the results returned with the essays to the pupils.

The class originally numbered about thirty members, but now consists of about a dozen pupils who seem to be really serious in mastering the many intricacies of their adopted calling.

Respectfully submitted,

George Sanders.

[The Directors hope, that while continuing the present class in more advanced studies, to commence the new year with a freshmen's class in all departments—together with such new developments as may seem practicable, with the limited time and means of study, which, under the circumstances, are found to be available.

Intending pupils are hereby notified that applications will be received at the San Francisco Art Association—where further information is obtainable.—Ed.]

The Slate Output of the Country in 1896 aggregated $2,746,205 in value, according to a special geological survey report submitted to the Secretary of the Interior. This is an increase of $47,505 over the previous year. Of the total, all but $482,457 was roofing slate. The value of products by states was: Pennsylvania, $1,726,318; Vermont, $609,506; Maine, $124, 086; Virginia, $107,883; New York, $82,492; Maryland, $72,142; Georgia, $20,388; Tennessee, $1,420; Massachusetts, $1,200; New Jersey, $700.

THE LEGAL STATUS OF THE PENNSYLVANIA CAPITOL COMPETITION.

THE PLAINTIFFS' CASE.

By the Court—The averments of the bill are substantially as follows:

That defendants are members of a commission appointed as provided by the act of April 14th, 1897 (P. L. 19), entitled: An act to provide for the erection of a new Capitol building for the use of the General Assembly, and to secure plans for said building and such other buildings to be erected in the future as may be necessary for executive and departmental purposes, and making an appropriation therefor." That pursuant to the powers and authority vested in them by this act, said Commissioners devised a method for the selection of an architect by competition and specially invited plaintiffs, who are architects, to take part in this competition; and that plaintiffs accepted the invitation. That the Commissioners published a programme, stating the terms of the competition, one of which provided for the selection of a board of experts to pass upon the merits of plans submitted, and that such experts were selected.

That by article 15, part two of the programme, it was provided that the Board of Experts should select from among the designs submitted to them, which should not have violated any of the requirements of the competition, those eight which in the judgement of the board were best, and should give to each a rank in accordance with its merits. That by article 20 of part two of the programme, the Commissioners undertook and agreed, after examination of the designs so presented by the Board of Experts and due consideration of their report and recommendations, to select one of the eight designs most satisfactory in their opinion, and upon ascertainment, in the manner provided for in article 21 of part two of the programme, of the name of the designer of the plan thus chosen as the most satisfactory, to award to such author the prize of the competition by designating and appointing him as the architect of the legislative building on the terms stated in the programme governing such appointment.

That they further undertook and agreed to award a first and second medal to the authors of the designs which should be placed respectively second and third in the competition.

That plaintiffs, at great labor and expense, prepared drawings, designs and specifications which conformed in all respects to the conditions and requirements of the programme, and duly delivered them to the secretary of the Commission.

That the Board of Experts selected the eight designs which in their judgment were best, assigning to each one its respective rank of merit, and presented these eight designs to the Commissioners, with a report of the proceedings of the board conforming in all respects to the requirements of the programme.

That thereupon it became the duty of the Commissioners under the provisions of the programme, after examination of the designs so presented and due consideration of the report and recommendations of the Board of Experts, to select the one of the said designs, in their opinion the most satisfactory, and to designate it as the first choice; and thereupon to identify the author of this design in the manner provided for in the programme, and to award to him the prize of the competition by designating and appointing him the architect of the legislative building. And that it was their further

duty, under the procedure provided for in the programme, to award the first and second medals to the authors of the designs which were respectively second and third in the competition.

That the commissioners have refused to carry out the procedure of the programme and to select an architect from among the authors of the eight designs which the Board of Experts reported to them and have notified plaintiffs that they have cancelled and annulled the provision of said programme.

The bill further alleges that the plaintiffs will sustain great and irreparable injury by this action of the Commissioners, that they have no adequate remedy at law for the injury thus done them and prays the Court to restrain the defendants from selecting an architect in any manner save that provided in the programme, and to decree them to specifically perform the provisions thereof for the selection of an architect, and to select as architect the author of one of the eight designs reported to them by the Board of Experts under the provisions of the programme, with a prayer for further relief.

THE DEFENDANTS' CONDITION.

To this bill defendants (all except Daniel H. Hastings) have demurred, assigning as grounds of demurrer that the court has no jurisdiction; that plaintiffs have no such interest in the subject matter as will entitle them to relief; and that the commission provided for by the act of April 14, 1897, is a deliberative body invested with discretionary powers in respect to the selection of an architect and the adoption of plans, and that the matters complained of in the bill are wholly within the discretionary powers of the Commissioners and a bill will not lie either to review or control the exercise of their discretion.

HISTORY OF THE CASE.

At the hearing on October 2, 1897, before the argument began, the counsel for the respective parties agreed "that the argument of this case upon demurrer shall go upon the understanding that: in the determination of the demurrer, the court shall be entitled to consider the report of the Board of Experts to the commission, and the resolutions passed by the commission under said report; and that a supplemental circular of invitation, dated the 10th of June, 1897, was mailed by the commission to all competing architects, although the complainants have no recollection of ever having received such report."

Looking at these documents thus brought on the record, we find that on July 31, the Board of Experts reported to the commission that they had given to the 30 designs submitted to them the most careful consideration and study, and had selected the eight designs, from among the 30, which in their judgment were the best, grading them from first to eighth, according to their respective merits: discussing these eight designs somewhat in detail; especially commending three and stating that "these three designs, numbers 21, 12 and 18, as already stated, seem to us the only ones worthy of your serious consideration. None of the remaining ones possesses the some order of ability in their authors."

That on September 9, 1897, the Commissioners met, and after consideration of the report of the Board of Experts, adopted certain preambles and resolutions, among which was the following:

"*Whereas*, The said Board of Experts have presented eight designs, which they report cannot be constructed without modification for the amount of the appropriation, thus disregarding the mandatory provision for the programme limiting cost, and none of which are for this reason, as also for reasons relating to light, air and other matters, satisfactory to the Commissioners: Now, therefore, after due consideration, the Commissioners do disapprove of the action of the Board of Experts in excluding from the competition the two designs referred to in their report and in not examining said designs, as also all designs submitted to them, and making report as to the relative merits of the same; and do also, for the reasons stated in the foregoing preamble, decline to approve the report submitted by said board." The Commissioners further resolved and directed that after the names of the several authors of designs submitted by the several architects had been ascertained, their secretary should "return the several designs to their respectiue authors," with the information (inter alia) that "none of said designs have been prepared in accordance with the mandatory provision of the programme limiting cost," and all of the designs were accordingly returned to their respective authors.

Dissatisfied with this action of the Commission, plaintiffs subsequently filed the bill now before us, to which, for the reasons already stated, defendants demurred.

DUTIES OF THE COMMISSIONERS AS PRESENTED IN THE ACT.

Upon the authority vested in, and the duties imposed upon the Commissioners must be ascertained from an examination of the act of April 14, 1897, above referred to. After declaring who shall be members of the Commission, the act provides that they "are hereby authorized and instructed to proceed with the least possible delay to procure the construction of a new Capitol building upon or near the site of the old Capitol building in the City of Harrisburg, of such size and form as may in their judgment be adapted to the present and future use of the General Assembly, its officers, committees and employees." It further enacts that "the said Commissioners shall, with the least possible delay, advise with and employ an architect or architects and adopt plans for the construction of said building, and such other buildings to be erected in the future as may be necessary for executive and departmental purposes," and that "the said Commissioners shall not, in the erection and construction of said new Capitol building, including the architect's services, contract for any expenditure in access of the sum of $550,000."

It thus appears that certain of the provisions of the act are mandatory upon the Commissioners. Thus the site of the building is expressly designated, and the style of architecture and the limit of price are prescribed. Other matters are left to the discretion and judgment of the Commission, such as the size and form of the building and its adaptability to the present and future use of the General Assembly, its officers, committees and employees; the employment of an architect or architects, and the adoption of plans for the construction of the building.

AS TO DELEGATING DISCRETION.

This act is the charter of the rights and duties of the Commissioners; and as it is a public act, not only they, but all persons dealing with them, are bound by its terms. Whatever it commands them to do they are bound to do; whatever it forbids, they cannot do; and whatever judgment and discretion is committed to them must be exercised by them alone, and cannot be committed to any other board or person.

The law on this subject is thus stated in Lyon vs. Jerome, 26 Wend., at page 494: "In all cases of delegated authority, where the delegation indicates any personal trust or confidence reposed in the agent, and especially where such personal trust or confidence is implied by making the exercises and application of the powers subject to the judgment or discretion of the agent or attorney, the general rule is that these are purely personal authorities, incapable of being again delegated to another unless a special power of substitution be added. From an early period of our law this rule has been laid down as to powers given by will or deed to executors, trustees and attorneys to sell land, make leases, etc.; and modern decisions have extended the principle to the less formal appointments of factors, brokers and other lawful agents. How much more strongly, therefore, must the rule apply to the delegation of authority by the State to its high public officers made with the solemnity of a legislative act?"

REGARDING PROGRAMME OF COMPETITION.

The provisions of the programme relied upon by plaintiffs must therefore be considered in the light of this principle. The programme is elaborate and voluminous, and after examining carefully its numerous parts and paragraphs, we are not surprised that a difference of opinion as to its purpose should have arisen between the Board of Experts and the majority of the Commissioners; and that this difference should be emphasized by the counsel on the opposite sides of this case. That this difference of opinion did exist as early as September 3 is apparent from the statement of one of the experts at the meeting of the Commissioners on that day, that "the whole purpose of the competition had been misunderstood; that it had been established solely with the view to the selection of an architect and not the selection of plans. It also appears from the tenor of the action of the Commissioners, which shows that they were looking for and passing upon the merits of plans with a view to obtain such as would, in the language of the act constituting the Commission, secure "a new Capitol building of such size and form as may in their judgment be adapted to the present and future use of the General Assembly, its officers, committees and employes." And as we have said, this difference of opinion was emphasized on the argument when counsel for plaintiffs contended that the competition was designed to secure the selection of an architect and not of a design or plan for the building; while the opposite counsel maintained that its purpose was to obtain a satisfactory plan, with the understanding that the author of the plan satisfactory to the Commission was to be employed to supervise its execution.

There certainly are paragraps and clauses in this elaborate programme which give color to each of these constructions. The programme is entitled: "Programme of a competition for the Selection of an Architect for the New Capitol Building to be Erected by the Commonwealth of Pennsylvania in Harrisburg." Paragraph five of part one states that "the object of the Commissioners in instituting this competition is to select and appoint an architect to design and supervise the new legislative building to be erected in Harrisburg, Pa." Paragraph seven of the same part that "the prize of this competition is the award of a commission to design and supervise the erection of said legislative building." These paragraphs and some others give plausibility to the argument that the design of the competition was the selection of an architect.

To be continued.

ILLUSTRATIONS.

ELEVATION of Proposed Club House for the San Francisco Yacht Club, Havens & Toepke, Architects.

THE DESIGN for stables and coach house at "Monte Robles" San Mateo County is the work of Architect Wm. F. Smith, and was erected for the late millionaire Col. C. F. Crocker who had the same love for fine horseflesh as the late Senator Stanford, whose breeding farm in the same county was celebrated the world over.

The foundations and walls of the building are of concrete, and show what can be done in this material to present a handsome attractive finish. The exterior walls present the appearance of rockfaced sandstone, laid in courses, while the inside is finished with a smooth surface, lined off, and forming the interior finish of the first story, and rendering the building virtually fire proof. The concrete work was done by Carl Griese whose address is 1318 Stanyan street, San Francisco. The carpenter work was done by a contractor residing at San Mateo, Mr. C. W. Wescott. For the plumbing and painting San Francisco men were employed. The former work was done by Mr. R. Rice of 107 Geary street, and nothing but standard open work plumbing was put in, every fixture having an independent cutt off to the sewer, as well as each stall, thus combining elegance and durability with fitness for service.

The painting was done by Mr. J. H. Keefe of 317 Sutter street, who is well known here for the excellence of the work done under his supervision. The exterior of the building was finished entirely with Cabot's stains, and the interior woodwork with shellac and varnish. There is no doubt that the completed building is one of the finest in the country for the purposes it is designed to fill, and reflects credit on both the designer and the mechanics whose ability and skill co-operated with the architect, to carry out his conception of how a perfect stable should be built and equipped.

TWO HOUSES for a large lot in the suburbs of San Francisco which can be built for twenty-eight hundred dollars each. The effort has been in the plan here presented to get the effect and convenience of an expensive house for a small amount of money by combining the two houses which will cost about $2800 each on a large lot and by omitting the usual fence between, a charming garden court can be had.

The arrangement of the rooms are such that plenty of sun can be had and porch space. The rooms are large and well arranged, the outside to be covered with iron lath and cemented. The main arch was to be of red brick, the roof of white cedar shingles. The cement work to be stained cream color and all sash to be white. All the rooms are bright and there are two fire places in each house of red brick, wide and open. The second story rooms have cove ceilings so as to fit the roof but are nine feet high and large and sunny. There is no waste room nor are the corners of the rooms cut

much by the roof as might be expected by the low eave lines, the space where such cut occurs being used as closet space or cupboards; the interior finish to be of Oregon pine or redwood. But novel and charming schemes for the rooms may be worked out with simple, cheap paper in quiet tones, burlaps, etc. The Oregon pine will take stains as good as as oak and some startling and pleasing effects can be had at small expense, plain clean pine vertical grain floors waxed make a good floor for rugs. There is a small cellar with cement floor and steps to same. The open court arranged between the houses would protect the garden from our summer winds and the wide porches facing same would be sheltered also, but would also get the sun. These houses are well adapted for two families who can work together and develop the gardens, etc., in their spare time changes in the plans such as adding sliding doors or closing up same can be easily made without disturbing the scheme.

THE BUILDING shown in our half-tone engraving this month is the handsome home of the Spring Valley Water Company, just completed by Architect Clinton Day. The many thousand stockholders in this company who have for years past been enjoying the dividends distributed with commendable regularity, by this company, do not need to be told of the firm and enduring base on which their prosperity rests. From small beginnings the growth of the company has kept pace with the growth and development of the metropolis of the west, and every native son and every native daughter, as well as those who are not native sons and daughters, have reason to be thankful for the abundant and unfailing supply of pure cold water with which San Francisco is blessed. That the public are fully convinced of the desirability of Spring Valley water stock as a safe and paying investment is shown by the frequency with which the stock is quoted above par. It is only fitting that such a successful enterprise should be housed in quarters befitting its importance and we think we will be pardoned if we devote more space to a description of the building and its builders, than we have lately given to our illustrations.

To begin with the building is six stories in height, of fire proof construction, and being situated on the south east corner of Geary and Stockton streets is very effectively viewed from Union Square. The main entrance is in the center of the Geary street facade, and leads the visitor through a finely tiled vestibule wainscotted with beautiful marbles to the rapidly running elevators whose ample service conducts to the commodious apartments on the upper floors of the building. The basement stories are of granite contrasting well with the buff brick and terra cotta finish of the upper portion of the structure. No modern improvements have been omitted in making the building a model of its class; in fact the architect seems to have vied with the engineer of the company as to which could construct the more enduring monument to his skill. (In this connection, and by way of parenthesis, we want to say a few words about another remarkable construction that owes its being to the president of the company, Mr. Charles Webb Howard: we refer to the remarkable crystal springs dam, the largest mass of solid concrete in the world, and which will remain for centuries to come a more enduring monument to the professional ability of its engineer Mr. Schusler, than any merely commemorative monument that could be erected.) This passing thought gives rise to the idea that possibly the architect of Spring Vallye's new building designed it with the intention to rival in his own profession the achievements of the rival profession of Engineering, as exemplified in the monster dam that successfully retains behind its ponderous mass, billions of gallons of clear sparkling water, always "on tap" for the hundreds of useful purposes to which it is daily and nightly applied by the thousands of men, women and children, the permanent inhabitants and transient guests of the western metropolis.

STEAM HEATING.

The contract for the steam heating apparatus was awarded to the Geo. H. Tay Company on account of the superiority of the system introduced by them. It is the Single Pipe Overhead System of low pressure steam heating, which is acknowledged to be the best, as by this method the basement is kept free from large pipes and the steam and condensation flow in same direction rendering the system entirely noiseless. The steam is taken from the boilers in the basement direct to the attic first, and is then led downwards to the floors. The steam descending heats the various rooms, halls and corridors. The boilers adopted are the Root Water tube boilers, which obtained the prize at the World's Fair at Chicago. The Geo. H. Tay Company are sole agents for these boilers on the Coast. The radiators used are the "Perfection," manufactured by the American Radiator Company, who are the largest manufacturers of radiators in the world. These radiators were also prize winners at Chicago. The Tay Company is also installing this same system at the present time in the Nevada Block, Flood Building, Alliance Assurance Building and W. T. Somers Building.

TERRA COTTA VS. CONCRETE.

Messrs. Gladding, McBean & Company the contractors for the Terra Cotta work in the Water Co's. Building endorse the following letter as expressing their views as to the relative merit of Terra Cotta vs. Concrete:

The debate between the advocates of terra cotta and concrete resembles the mighty competition of a circus and "side show." While one is considered a legitimate entertainment, the other is contented to be called a 'side show,' and gather its patronage by the lights which illuminate the mammoth tent. But when the circus moves, what happens?

"Peace be to their ashes," seems a peculiar fitting blessing for the advocates of both these systems. Yet could either be subjected to the thorough treatment of their respective methods, "ashes" would no longer express their future state, but in its place would be used terms of "terra cotta" or "concrete," and if concrete dared hope for complete converts 'ashes' would become obsolete.

Thoughtfully, what lesson has been taught by the Pittsburg fire, from which the lengthy argument got its initial momentum? Simply that terra cotta did all that was claimed for it; that no other system ever had such a test; that concrete, where used in a building with a fire that is commonly called a "blaze," protected by wind, time, isolation and the whole fire department, showed unusual weakness, and that the architects having the restoration of the Home Store Building in charge are satisfied with the test, and are to use terra cotta for the reconstruction, and that the weakness show up by the concrete with this incipient fire displayed its faults, and none of its advocates would have cared to have

had a general inspection immediately after the fire, as such would have caused a lasting injury.

It has shown one thing, however, and that is the shrewdness of the business men who have taken to the advocating of concrete as a business venture. Many, to read their letters to-day, and not knowing the facts relative to this Pittsburg fire, would suppose that all this contention originated from equal tests in an actual fire. They have created among the laymen whom they defend the impression that their system has actually demonstrated fire-resisting qualities under a severe trial.

There have been many reports from chiefs of several different professions—engineers, fire underwriters, building experts and fire-proofing concerns—and all agree that terra cotta was eminently successful. The last report, however, made by a commission of capable engineers and sent to adjust the loss, to condemn all the seriously injured steel and suggest means of using that which has received slight injury, and approve that which was considered proper to stand, after thorough inspection, is to the effect that all iron work not displaced or deformed by the falling of an immense water tank was not seriously enough injured to require removal. Then comes the crumb from which the concrete advocates try and feed the multitude. These same engineers, after making so favorable a report, suggest that some other system should be adopted to more thoroughly protect the steel from heat and a consequent expansion, and recommend concrete. Why a change if the steel is all right? Why concrete, even though a change be desirable? This fire demonstrated no qualities for concrete, but instead, quite the reverse. Where were the weak points of protection to the steel where the construction was with terra cotta? Not where terra cotta was used, but where it was omitted. If more protection for the steel is needed, why not more terra cotta? This material has stood the test in the worst conflagration known for years, and why change for one that an ordinary fire so completely injured that it should and probably will be replaced?

Terra cotta is siill supreme, and concrete will have to prove further than a simple claim that it stands within "hailing distance" of this superior material. Cannot the users, builders and owners see for themselves whether claims are set forth for terra cotta that it cannot fulfill as well as any body of men whose trade or profession is as distinctly different from fire-proofing as dry goods are from groceries? Concrete has been too long in the field not to have known its qualities, and nothing new has been added to it that makes it better to-day for fire-proofing than many years ago. —*F. F. Fernald in Clay Worker.*

CONCRETE VS. TERRA COTTA.

The following extract from a letter published in *Cement and Engineering News*, expressing the views of Mr. L. B. Jenny on what he terms "The Best Fire Proof Construction for Buildings Occupied for Mercantile Purposes," meets the views of Mr. Geo. Goodman, who had the contract for the Concrete Work in the Water Co's Building—and who sends in the following estimate of Mr. Jenney's standing as an architect:

Mr. W. L. B. Jenney of Chicago is one of the most celebrated architects in the United States, and the inventor of the modern steel office building. He has revolutionized th system of high building construction and speaks with authority upon the subject of fireproof construction.

Mr. Jenney says the most important lesson taught by the fire of last May in Pittsburg was the lack of strength displayed by the fire-clay fire-proofing. The buildings were permitted to move in any direction without any material restriction by the fire-proofing. The floor arches showed by the scaling off of the lower webs that they were unable to offer any sufficient force to counteract the tendency to lateral motion. The column protection although composed of the very best obtainable kind of fire-clay tile was also not of sufficient strength.

Owing to the fact that steel columns or girders or beams after being subjected to a long continued fire will assume the same temperature as fire-proofing, and owing to the fact futhermore, that the rate of expansion of the steel is much greater than that of the fire-clay tile, destructive movements are permitted which, as shown in this experience, will result in considerable damage and which damage will increase in direct proportion to the heighth of the building.

In view of these important developments, it is our opinion that important structures of this class thould have a radically different method of fireproofing. The fireproofing should be in it self strong and able to resist severe shocks, and should, if possible, be able to prevent the expansion of the steel work.

There seems to be but one material that is now known that could be utilized to accomplish these results and that is first-class concrete.

BOOKS AND PERIODICALS.

A SYSTEM OF EASY LETTERING by J. Howard Cromwell, Ph. B. Published by Spon & Chamberlain, 12 Cortlandt street, New York, price 50 cts.

The simplicity of this system should recommend it to the student of architecture. The preface of this volume gives the system as follows:

"The formality of a preface may seem scarcely necessary for the supplementing of a system as simple and comprehensible as the one herewith presented. We have but to divide any surface we may wish to letter into squares (or parallelograms as the case may be), in pencil lines; form the required letters, in ink or paint, and according to the style chosen; erace the pencil lines, and the lettering is complete."

LIPPINCOTT'S Magazine for November, 1897, has for a complete novel "The Price of a Wife" by John Strange Winter (Mrs. Stannard).

It is a tale of English domestic life, and one of the best

which the author of "Bootles Baby" has written of late years. To those who have read "Bootles Baby" this novel will be welcome, and to those who have not they will be sure to want to do so after reading "The Price of a Wife". The other contents are as interesting as usual.

LABORATORY OF TESTS AND TECHNOLOGY of the Philadelphia Commercial Museum. Instruction for submitting samples, general information and schedule of official fees. Philadelphia, 1897.

This Laboratory has been established as an adjunct of the Scientific Department of the Philadelphia Commercial Museum. It has for its main object the examination and analysis of raw and manufactured products, which may be sent to it from any of the countries represented in its collections, or from private individuals, who wish to determine through chemical and other tests the commercial value of the materials presented.

UNITED STATES DEPARTMENT OF AGRICULTURE. Division of Forestry. Circular No. 17. Recent Legislation on State Forestry Commissions and Forest Reserves.

In Circular No. 13, of this division, the existing forest fire legislation of the several States and Territories was summarized. Since it appeared, in March 1896, several States have enacted legislation for the erection of forestry commissions and the establishment of forest reservations, and public interest in these important subjects has been greatly stimulated. This increased interest is evidenced in the many requests which reach the Division of Forestry for aid in formulating legislation affecting forest conditions, and it is believed this summary of the more important recently enacted laws will be of material service in work of this kind.

FINAL REPORT OF THE WORLD'S FAIR COMMISSION, including a description of all exhibits from the State of California, collected and maintained under Legislative Enactments, of the World's Fair Columbian Exposition, Chicago, 1893.

This handsome volume of over 300 pages, fully illustrated with views of the California Building as well as the various exhibits from various parts of the State, certainly does much credit to the State, as well as to the following gentlemen who composed the California World's Fair Commission:

Irving M. Scott, President; James D. Phelan, Vice-President; R. McMurry, A. T. Hatch, S. W. Fergusson, L. J. Ross, W. P. Mathews. The fact that of $300,000 appropriated by the State to this Commission over $20,000 was returned to the State should stand to the credit of this Commission as gentlemen who have certainly been faithful to this trust.

LABOR QUESTION IN CHINA.

WHERE is no place in the world where the labor question is so easily solved as in China. There are no lockouts or strikers, nor have there been any for upwards of 2,000 years. The bricklayers, plasterers, carpenters and tinsmiths form lines on either side of the public square and wait until they are wanted. The master builder comes along and puts a chalk mark upon those whose services he requires. They follow him and go to work. No quarrel about wages or overtime. The least sign of discontent calls for the head of the kicker. All are glad to see it fall into the basket, for it gives place for one more to work. The master builder, however, does not have things his own way. There is a fixed rate of wages for each trade, which he must pay, and a certain number of hours defined, above which the employers must not go, only by special permit from the government, and overtime must be paid for accordingly. Once a man employed, he receives his daily pay whether he works or not, so long as the work he is engaged on is not completed, so that if the work is "outside" and rain prevents it going on with, he receives his pay just the same. Loss of time by rain is borne by the owner, so the contractor suffers no loss on this account. Failure to conform to the contract, or to pay wages due his workmen, render the contractor liable to decapitation. The owner, too, is liable to the workmen and material men equally with the contractor. This is a lien law with a vengeance, for in case of failure to pay the workmen, the government pays the debts, confiscates the property, makes headless the culprits, and the whole thing is settled in a few days to the satisfaction of every one but the widows and orphans of owner and contractor. How nice it must be in China to have the labor question settled so promptly!

MARINE SALT IN PLASTER.

ONE of the causes of the decay of the frescoes in the Houses of Parliament is supposed to arise from the use of plaster which was prepared from limestone from Durdham Down, near Bristol. All the beds of Durdham Down limestone are of marine origin, being full of marine shells; and, although in the long lapse of ages since they were deposited, the marine salt, whith which the stone must have been saturated, has for the most part been washed out, yet still a trace of it remains, insensible to an ordinary analysis. It is the general practice to burn this stone into lime with braize (or cinder taken from the scavenger's yard), and this braize always contains sulphur. In burning the minute quantity of marine salt in the stone is coverted, for the most part, into sulphate of soda, or the salt well known in commerce as "Glauber salt." On most of the walls that grow cold in winter needle form crystals are found, varying from a bloom 1-100 of an inch to needles of an inch in length, and in some instances, in damp old walls, such as the cloister walls of a cathedral, the crystals stand out to the length of 1½ inch. They are generally composed of sulphate of soda, in rare instances mixed with nitrate of potash, and sometimes with small quantities of muriate of lime and magnesia. When the weather becomes dry all these bunches of crystal effloresce and are converted in to a lose white powder, much of which drops from the wall, carrying with it shales of plaster, or flakes of paint, or film of whatever material the surface of the wall is covered with. Moisture will condense on the wall if allowed to grow cold in damp weather; the white powder is then dissolved and the liquor, a solution of sulphate of soda, is absorbed by the mortar or plaster. Architects are in the habit of proving the value of the various kinds of stone presented for their use, for the endurance of frost, by a saturated solution of sulphate of soda, similar to this liquor, which on crystallizing imitates the heaving and splitting action of ice forming from water. Accordingly, this liquor is no sooner absorbed as the wall dries than it aggregates into ice like crystals and the plaster is disintegrated and heaved by the dynamical force developed in their formation. The plaster having sustained this injury, the salt transforms itself and shoots out into bunches of needle form crystals, only to fall again into the terrible white powder, as the air becomes warm and dry. Thus a constant succession goes on of solution and desiccation, with the changes of the weather and temperature; and if the wall be permitted to cool with the frost, the ruin of the plaster is insured. Sulphate of soda exists not only in Durdham Down limestone, but unfortunately also in much abundance in all the lias motars, in London clays and in many other stones. In fact, it may be doubted if any London wall is free from its presence. We may, therefore, observe this kind of action of destruction going on more or less almost everywhere. In Rome and Florence, indeed, many frescoes have remained entire, with their colors smooth and in good order, for hundreds of years.—*Architecture and Building*.

PATENT CHIMNEYS ON THE MILLS BUILDING.

CHIMNEY TOPS.

CHIMNEY TOPS extending from the flues in Jas G. Fair's Building to the top of the Mills Building. This work was done by L. E. Clawson & Co. of 1340 Market street, using Gladding, McBean & Co's flue linings and tops. Each joint of pipe was double braced four inches into the wall with wrought iron strong enough to support each joint, the whole being earthquake proof. The joints were wet when placed into position and grouted together with Portland Cement which makes the whole breast as solid as though it were part of the building. The offsets in the chimney are made so as to clear the windows and also the iron frame work that supports the cornice of the Mills Building, which projects five feet. The tops above the cornice are Gladding, McBean & Co.'s no. 143. They are braced with wrought iron bolted to fire wall, thus making a perfectly secure chimney. The manager and master mechanic of the Mills Building, are so well pleased with the work that they suggested that it be photographed. The cost of this kind of work exceeds that of galvanized iron but a trifle. L. E. Clawson & Co. make a specialty of all kinds of chimney work and are experts in the curing of smoky chimneys and are prepared to do work in their line at short notice.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street,

Seth Babson, Pres. H. A. Schultz, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Theo. A. Eisen, Pres. Arthur B. Benton, Vice-Pres.
William C. Aiken, Sec't. August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

Jos. C. Hornblower, Pres. Jas. G. Hill, Vice-Pres.
E. W. Dunn, Jr., Sec. W. J. Marsh, Treas.

Association of Architects of Arizona, [meetings held at Phoenix, Arizona.

D. W. Millard, Pres. T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

E. J. Molera, Pres. W. F. C. Hasson, Vice-Pres.
Otto Von Geldern, Sec. Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

S. H. Kent, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Bilck, Pres. M. V. Brady, Sec.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

Rights of Adjoining Landowners.—Where a lot owner erects a building on one side of same, he cannot enjoin the adjoining lot owner from erecting a high board fence on his line, although it shuts off the light and air from such building.

Triplett v. Jackson, App. Ct. Kans., 48 Pacific Rep. 931.

Precedence of Contractor's Orders.—A contractor having given a bond providing that, before he can receive his pay, all claims against him for labor and materials entering into the construction of the building must be paid, orders given by him upon the owners of the building do not constitute an equitable assignment of the funds owing him in their hands, and they have the right to first pay subsequent orders given by him in favor of laborers and material men.

Hall Co. v. Lloyd Bros. Co. Ohio Cir. Court, 7 Ohio Dec. 203.

Iowa Party Wall Valid.—The law of Iowa (Code sec. 2019) which provides that a party wall may be built on an adjoining lot to the extent of nine inches, without the consent of the owner, but that he shall not be liable for any of the expense for building same, unless he makes use of it, is not unconstitutional as not being taken under due process of law, or as taking private property without compensation.

Swift v. Calnan, Supreme Court Iowa, 71 Northwestern Rep. 233.

Owner's Dealings with Subcontractor.—An owner may contract with a subcontractor for extras, without regard to the provisions relating to extras in the contract between him and the general contractor; and the furnishing of extra labor and material by a subcontractor at the direction of the owner creates a contract on sufficient consideration to render the owner liable to him for such extras.

Foley v. Tipton Hotel Co., Supreme Court Iowa, 71 Northwestern Rep. 236.

When Architect's Certificate Cannot be Required.—Where a builder's contract provides that for all payments a certificate, signed by the architect, as the owner's agent, shall be obtained, a discharge of the architect excuses the contractor from furnishing such certificate.

Fitts & Co. v. Reinhardt, Supreme Ct. Iowa, 71 Northwestern Rep. 227.

Amount of Damages Must be Proven.—Though an owner has been put to extra expense on account of failure of contractor to finish his work as required by the contract, yet if the evidence fails to show how much he had to expend to complete such work, he cannot have same effect as a counterclaim.

Fitts v. Reinhardt, Supreme Ct. Iowa, 71 Northwestern Rep. 227.

BUSINESS MOSAICS.

Parties in want of handsome fixtures for bath room, lavatory or water closets would do well to call upon Mr. M. S. James who represents the Pacific Coast for The J. L. Mott Iron Works. Mr. James has his office at the Flood Building, room 27, where various Sanitary Specialties can be seen, circulars sent on application.

The Titus Patent Improved Gas Trap, Tide and Flushing Gate. This Improved Trap is highly recommended by the most competent authority. See the following certificate:

This is to certify that the Titus Sewer Trap has been in use in building occupied by us for the last twelve years—during which time it has given entire satisfaction.

Baker & Hamilton, by F. Dassonville.

This is to certify that that are three Titus Sewer Traps on this property—Cosmopolitan Hotel, Fifth and Mission streets—for twelve years and they have given perfect satisfaction during that time.

N. Irvine, Engineer for Donahoe Estate.

Mr. G. C. Dallamore the practical plumber, gas and steam fitter, can be found at his office, 414 Devisadero street, bet. Oak and Fell, tel. Pine 1405. Sanitary plumbing and sewerage ventilation a specialty. Personal supervision given all work.

Black Daddy—"Didn't I tole yo' not to go in swimmin' wif a white boy?" Son—"He wasn't white, daddy, when he fust come in."—*Ex.*

The rapid advancement that has been made within the past few years in architecture, and the varied styles now in vogue, have made the question of house painting of greatest importance.

As the cost of applying paint will average twice the cost of material it is of the first importance that the paint employed should be of the best obtainable quality—as the trifling additional outlay for materials will be many times repaid by the superior durability and satisfactory appearance of a first class article.

All prepared or liquid paints which in addition to the usual grinding and mixing, should be ground while in the liquid state as the second grinding brings the oil and pigments into more intimate combination, and gives a uniformity of consistency not to be obtained by mere mixings.

The H. W. Johns' Manufacturing Company in writing on this subject make the broad claim that their liquid paints are so prepared furthermore that they are the only manufacturers who give to their goods the second grinding in the liquid state.

The subject is certainly worthy of special study and as all our readers are interested and Messrs. Henshaw, Grant & Co., the special sales agents, 46-48 Fremont street, are well supplied with literature which can be had for the asking. The H. W. Johns' Manufactured Liquid Paints are now the U. S. Government Standard of purity and durability.

Mr. Ferd. L. Pfingst, 94 Chronicle Building, importer of Hardwood Lumber and Veneers, Maple and Oak Flooring, is prepared at all times to figure on any size contracts.

CITY BUILDING NEWS.

Baker near Vallejo. Two-story frame; owner, A. J. Ferguson; architects, Coxhead & Coxhead; contractors, Hannah Bros; signed, Oct. 2; filed, Oct. 15; cost $2812.

Broadway and Scott. Two-story frame; owner, W. F. Herrin; architect, J. E. Kraft; contractors, Mallory & Swenson; signed, Oct. 25; filed, Nov. 8; cost $8071.

California and Scott. Alterations and additions; owner, Mrs. Hettie M. Redfisch; architect, Albert Sutton; contractors, Walker Bros. & Co; signed, Oct. 11; filed, Oct. 12; cost $2000.

Castro near 18th. Two-story frame; owner, Andrew Spalding; contractor, Wm. Helbing; signed, Nov. 6; filed, Nov. 8; cost $3870.

Cedar Ave. near Larkin. Additions and alterations; owners, Seymour and Ester Attell; architects, Townsend & Wyneken; contractor, F. V. Acker; signed, Nov. 15; filed, Nov. 15; cost $1800.

Clay and Baker. Stone work for basement; owner, Mrs. Ellen Session; architects, McDougall Bros; contractor, Gray Bros; signed, Nov. 13; filed, Nov. 13; cost $1100.

Clay and Baker. To build except stone work; owner, Mrs. Ellen Sessions; architects, McDougall Bros; contractor, J. H. McKay; signed, Nov. 13; filed, Nov. 15; cost $6200. Painting; contractor, John Quadt; cost $804.

Clipper near Church. To build; owner, Gus. Bronig; contractor, C. Erikson signed, Oct. 7, filed, Oct. 12; cost $1580.

Eddy and Mason. Carpentry, mill work, etc., for six-story brick and iron building; owner, Farbizio Nigro; architects, Mooser & Son; contractors, Campbell & Pettus; signed, Oct. 30; filed, Nov. 6; cost $30,034. Granite and brick work; contractor, D. J. Brennan; signed, Oct. 30; filed, Nov. 6; cost $14,700. Wrought iron work, etc.; signed, Oct. 29; filed, Nov. 6; cost $6980. Wiring for incandesent light; contractors, Will & Finck Co; signed, Oct. 30; filed, Nov. 6; cost $1275. Marble wainscoting; contractors, A. Pallinghi & Co; signed, Nov. 4; filed, Nov. 6; cost $1246.50. Cast iron work; contractor, Vulcan Iron Works; signed, Oct. 30; filed, Nov. 6; cost $5390. Elevator work; contractors, Cahill & Hall; signed, Oct. 30; filed, Nov. 6; cost $8265. Mosaic floors, etc; contractors, W. W. Montague & Co; signed, Oct. 30; filed, Nov. 6; cost $2300. Plumbing, etc; contractor, H. Williamson; signed, Oct. 30; filed, Nov. 6; cost $2500. Plumbing, etc; contractor, H. Williamson; signed, Oct. 30; filed, Nov. 6; cost $2100.

Eddy near Hyde. Two-story frame; owner, T. N. Holm; architect, E. J. Vogel; contractor, I. W. Coburn; signed, Nov. 2; filed, Nov. 3; cost $3150.

Eddy near Van Ness Ave. Three-story frame; owner, Ann Smith; architect, Thomas J. Welsh; contractor, J. E. Mooney; signed, Oct. 5; filed, Oct. 20; cost $7700. Sewering, etc; contractor, W. F. Wilson; signed, Oct. 5; filed, Oct. 20; cost $1400.

Eighteenth near Church. Two-story frame; owner, Charles Wagner; architect, B. R. Van Deusen; contractor, Thos. B. Goodwin; signed, Nov. 3; filed, Nov. 3; cost $3190.

Eighteenth near Church. One-story frame; owner, Lorentz Entzminger; architect, B. R. Van Deusen; contractor, T. B. Goodwin; signed, Nov. 3; filed, Nov. 3; cost $1615.

Eighteenth and Harrison. Addition to factory; owner, Mission Soap and Candle Works; architect, T. Schmittacher; contractor, Thomas O'Connor; signed, Nov. 11; filed, Nov. 12; cost $1132.

Eleventh near M. Cottage; owner, Mrs. Julia Sweeney; architect, M. G. Bugbee; contractor, W. Sorenson; signed, Oct. 13; filed, Oct. 15; cost $1013.

Ellis and Anna Lane. Plumbing, marble work, etc; owner, W. J. Somers; architects, Percy & Hamilton; contractors, Gulick & Wetherbee; signed, Oct. 15; filed, Oct. 20; cost $4810. Marble wainscoting and stairs, etc; contractors, Ruffino & Bianchi; signed, Oct. 16; filed, Oct. 20; cost $3464.

Ellis near Mason. Plastering; owner, L. H. Sly; contractor, W. C. Watson; signed, Oct. 20; filed, Oct. 26; cost $4600.

Flood Ave., Sunnyside. Cottage; owner, Walter Bassett; builders, McCarthy Co; cost $1300.

Fillmore near Clay. Concrete, brick and iron for alterations; owner, Gertrude S. Bowers; architects, Hermann & Swain; contractors, Gray Bros; signed, Nov. 1; filed, Nov. 1; cost $1600.

Fifteenth near Howard. Two-story frame; owner, Margaret Keane; contractor, C. J. Antwiber; signed, Nov. 6; filed, Nov. 9; cost $2870.

Franklin and Locust. Additions and alterations; owner, Charlotte Windhauer; architects, Salfield & Kohlberg; contractors, Bucher & Frahs; signed, Nov. 13; filed, Nov. 13; cost $2450.

Geary near Powell. Additions and alterations; owner, Mrs. Golda Alexander; architects, Havens & Toepke; contractor, Jas. Geary; signed, Oct. 11; filed, Oct. 22; cost $4550.

Green street wharf. Widening wharf; owners, Board of Harbor Commissioners; contractors, Healy, Tibbits & Co.; cost $17,382.

Haight near Octavia. Three-story frame; owner, Barbara Schaletzer; architect, J. J. Laferme; signed, Nov. 2; filed, Nov. 3; cost $3490.

Howard near 9th. Additions; owner, Mr. Ambrose; day's work; cost $1000.

Howard near 16th. To build; owner, C. H. Randall; contractor, W. W. Redmall; signed, Nov. 3; filed, Nov. 3; cost $4500.

Hyde and Bay. Two-story frame; owner, Adam Ulm; contractor, Frank Steinman; signed, Oct. 29; filed, Oct. 30; cost $3000.

Hyde near Green. To build; owner, Patrick Dugan; architects, Shea & Shea; contractor, P. G. McIntyre; signed, Nov. 3; filed, Nov. 8; cost $2500.

Jackson near Gough. Two-story frame; owner, Henry Lund; architect, W. H. Lillie; contractor, J. G. Adams; signed, Oct. 25; filed, Oct. 27; cost $8700. Plumbing, etc; contractor, G. C. Sweeney; signed, Oct. 25; filed, Oct. 27; cost $1355.

Laguna and Olive Ave. Painting; owner, L. Kutner; architect, W. J. Cuthbertson; contractor, W. Shafer; signed, Nov. 19; cost $735.

Lake near 13th Ave. To build; owner, Rose B. Gddard; contractors, Marcuse & Remmell; signed, Nov. 4; filed, Nov. 4; cost $1800.

Larkin near McAllister. Two-story brick; owners, Jacob and Jeremiah Browning; architects, Townsend & Wyneken; contractor, R. Parker; signed, Oct. 14; filed, Oct. 14; cost $6100.

Larkin and McAllister. Two-story brick; owners, Jacob and Jeremiah Browning; architects, Townsend & Wyneken; contractor, Rufus Parker; sub-contractors, Miller & Beck; signed, Oct. 18; filed, Oct. 18; cost $2084.

Larkin and Jackson. Three-story frame; owner, Elizabeth W. Baldwin; architect, E. J. Vogel; contractor, J. W. Coburn; signed, Oct. 19; filed, Oct. 20; cost $7300.

Market and 3d. Mosaic work; owner, Mrs. P. A. Hearst; architect, A. C. Schweinfurth; contractor, Campomenosi & Co; signed, Nov. 5; filed, Nov. 6; cost $4122.

Market and 3d. Prismatic sidewalk lights, etc; owner, Claus Spreckels; architects Reid Bros; contractor, P. H. Jackson & Co; signed, Oct. 17; filed, Oct. 20; cost $4536. Kitchen apparatus; contractor, W. W. Montagne & Co; signed, Sept. 28; filed, Oct. 20; cost $1215.

Market and 3d. Finishing wood work for bank; owner, Claus Spreckels; architects, Reid Bros; contractor, West Coast Furniture Co; signed, Oct. 8; filed, Oct. 26; cost $1786. Interior finish for "Call" office; contractors, Fink & Schindler; signed, Sep. 28; filed, Oct. 26; cost $2457.

Market and 3d. Electric light fixture; owner, Mrs. P. A. Hearst; architect, A. C. Schweinfurth; contractor, Cal Art Metal Co; signed, Oct. 22; filed, Nov. 1; cost $3750. Electric elevator; contractor, Sprague Electric Elevator Co, N. Y.; signed, Oct. 1; filed, Nov. 1; cost $10,850.

Market street. Clock for Ferry Depot; owners, Board of Harbor Commissioners; contractor, Howard Clock Co; cost $3630.

Maple near Clay. Two-story frame; owner, C. Beckmann; architect, P. H. Bosworth; signed, Oct. 16; filed, Oct. 18; cost $2800.

McAllister and Baker. Two-story frame; owner, R. Wannermacker; architects Salfield & Kohlberg; contractor, Jos. Bucher; cost $2210.

Mission near 17th. Alteration and additions; owner, S. Nathan; architects, Copeland and Pierce; contractor, Paul Carnouche; signed, Oct. 15; filed, Oct. 18; cost $2615.

Noe and Jersey. Alterations and additions; owner, Peter F. Gilroy; architect, G. A. Dodge; contractors, Moore & Cameron; signed, Nov. 9; filed, Nov. 10; cost $1615.

Page near Pierce. To build; owner, W. J. Conrad; architects, Shea & Shea; contractor, B. Dreger; signed, Oct. 20; filed, Oct 26; cost $4029.

Parnassus Ave. near 4th Ave. Lathing and plastering for Affiliated Colleges; owner, University of California, architects, Martens & Coffey and Kraft; contractor, Silas Carle; sub-contractor, Charles Dunlop; signed, Oct. 12; filed, Oct. 14; cost $15,695.

Pennsylvania Ave. near 18th. Two-story frame; owner, Thomas Brady; architect, M. J. Welsh; contractor, J. A. McDonald; signed, Oct. 11; filed, Oct. 12; cost $2300.

Pine near Dupont. Alteration and additions; owner, D. Cuneo; architect, E. Depierre; contractor, P. A. Antorelli; signed, Oct. 30; filed, Nov. 2; cost $1500.

Post near Gough. Alterations and alterations; owner, Minna Goslinsky; architect, M. J. Lyon; contractor, G. H. Moore; signed, Oct. 19; filed, Oct. 20; cost $1600.

Sacramento near Drumm. Alterations and additions; owner, City of San Francisco; architect, C. Wilson; contractor, C. F. Sheibley; cost $1860.

Sacramento near Davis. Raising and alterations; owner, H. E. Bothin; architects, Percy & Hamilton; contractor, B. F. Ellis; signed, Nov. 2; filed, Nov. 4; cost $9000.

Second and Mission. Granite work for six-story brick; owners, Wells, Fargo & Co; architects, Percy & Hamilton; contractors, Raymond Granite Co; signed, Oct. 21; filed, Oct. 22; cost $48,240.

Seventh Ave. near San Francisco. Alterations and additions; owner, Mrs. L. O'Brien; contractor, Henry Behrens; bond $800.

Stockton and Geary. Granite brick and iron work for five-story brick; owner, Estate of Wm. T. Coleman; architects, Pissis & Moore; contractor, M. V. Brady; signed, Oct. 12; filed, Oct. 26; cost $9090. Sandstone work; contractor, McGilvray Stone Co; signed, Oct. 12; filed, Oct. 26; cost $11,960.99 Carpentry, plastering, etc; contractor, Silas Carle; signed, Oct. 12; filed, Oct 26; cost $10,995. Plumbing, etc; contractors, Duffy Bros; signed, Oct. 12; filed, Oct. 26; cost $4800.

Stevenson and 4th. Plumbing, etc; owner, Claus Spreckels; architects, Reid Bros; contractor, W. F. Wilson; filed, Oct. 26; cost $2982. Electric wiring, etc; contractors, Cal. Electric Works; signed, Sept. 24; filed, Oct. 26; cost $4441. Elevator; contractors, Cahill and Hall Co; signed, Oct. 7; filed, Oct. 26; cost $1975.

Taylor and Turk. Electric elevator; owner, A. W. Wilson; architects, Shea & Shea; contractor, Central Iron Works of Quiney, Ill; signed, Oct. 4; filed, Oct. 14; cost $2237.

Texas near Maraposa. Cottage; owner, W. S. Taylor; contractor, R. O. Davis; signed, Oct. 27; filed, Nov. 1; cost $1450.

Tenth Ave. near Cement. To build; owner, M. I. Cornell; contractors, Marcuse & Remmell; signed, Nov. 1; filed, Nov. 2; cost $2430.

Tenth Ave. near M. To build; owner, W. T. Beck; day's work; cost $3000.

Thirteenth near Guerrero. To build; owner, Ellen F. Kennedy; contractor, Ed. Cox; signed, Oct. 30; filed, Nov. 1; cost $2623.

Tilden near President. Cottage; owner, Miss Petranella Mickelson; architect, T. P. Ross; contractor, Fred Miller; signed, Oct. 18; filed, Oct. 20; cost $1375.

Turk near Mason. Plumbing; owner, G. G. Burnett; architect, J. E. Wolfe; contractors, Ickelheimer & Bros; cost $757.

Union and Hyde. Two-story frome; owner, Catherine Powers; architects Shea & Shea; contractor, L. M. Weismann; signed, Oct. 7; filed, Oct. 16; cost $2497.

Utah and Center. Cottage; owner, Thomas Thompson; architect, H. A. Schulze; contractor, Henry Jacks; signed, Oct. 25; filed, Oct. 29; cost $1885.

Valencia near 14th. To build; owner, James R. Carrick; contractor, A. C. Soule; signed, Oct. 1; filed, Oct. 14; cost $9000.

Van Ness Ave, Geary. Brick building; owner, Ladies Protection and Relief Society; architect, Clinton Day; contractors, Peacock & Halliday; signed, Oct. 8; filed, Oct. 14; cost $3394.67.

Van Ness Ave. and Olive Ave. Plumbing, etc; owner, J. Frownfeldt Trustee; architects, Salfield & Kohlberg; contractors, Ickelheimer and Bros; cost $3000.

Van Ness Ave near Union. Two-story frame; owner, C. H. Rehnstrom; contractor, Wiren and Peterson; signed, Nov. 5; filed, Nov. 13; cost $5756.

Washington near Spruce. To build; owner, Livingston Jenks; architect, J. E. Kraft; contractor, Henry Jacks; signed, Oct. 11; filed, Oct. 27; cost $5400.

Wisconsin near 22d. Cottage; owner, James McKinley; architect, G. A. Bordwell; contractor, R. O. Davis; signed, Nov. 1; filed, Nov. 1; cost $1086.

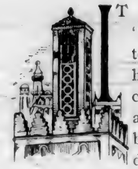
VOLUME XVIII. DECEM 20th, 1897. NUMBER 12.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

THE WAY that the devil was fooled by the Architect of the Cologne Cathedral according to the legend reminds one forcibly of the way many a poor devil of an architect has been fooled by those who wish to dispense with his services when about to build but still wishes the benefit of his brains. The devil it seems showed the architect the plans of a beautiful Cathedral thinking that he would be willing to sell him his soul for these well designed plans. But the Architect committed the salient points to memory while his satanic majesty was explaining—and therefore was able to tell such majesty that "the plans did not please him and he would not take them."

In these days he had only to get hold of a copy of the blue prints and need not have taxed his memory to such an extent—or he could have sent his wife to the building and borrowed the blue prints from the contractor on the pretense that she was about to build and if said plans suited her she would employ the obliging contractor and thus save the expense of an architect.

THE "TRUMPH" OF MODERN ARCHITECTURE—"HIGH BUILDING" IN OUR CITIES.



IT IS ASSERTED periodically that the "greatest advance of our modern architecture" is in great office buildings. It has been said by one of our architectural critics, in an article treating of modern city architecture, that the modern city office building or commercial structure may be defined as representing the "apotheosis of a cube."

We may rightly ask whether such commonplace, prosaic, structures (as many of them are) can in their riotous banality be considered as worthy of notice. While inspecting examples of such buildings and studying published designs, it occurred to the writer that it would be well to make an examination and analysis of this department of modern design, to ascertain, if possible, how much there may be in it which really counts as an *advance* in architectural evolution, and if such buildings can really be classed as architecture at all, or merely as util tarian constructions masquerading in an external disguise of architectural "features," more or less skillfully applied. Most of us have heard or read a book called "Cliff Dwellers" written by a Chicago author. The aptness of this title is obvious. These great piles certainly recall, in a sense, mountains or cliffs perforated with a huge "rabbit warren" a congeries of dwellings or rooms, such as ancient nations might have made for themselves in some situations to avoid the labor of erecting isolated buildings. The modern buildings of the class considered however, fail in an architectural sense They never could approach the Rock Cut Temples of India in point of architectural impressiveness from the mere fact that they are composed of story on story in succession, all monotonously alike.

What have we at the present day with all our boasted "progress" in architecture or otherwise to compare with the works of ancient times?

It is certainly an acknowledged fact that all of the ancient buildings which are typical, and from which architectural forms have been derived and handed down by a process of evolution, are buildings of *one story*, the modern idea of a building in stories or tiers or stages not even being hinted at until a certain period in the history of Rome, and even then the division of a building into stories by superposed "orders," as seen in the Coliseum or elsewhere, was a chance expedient for "decorative" effect, borrowed from the post and lintel system of the Greeks.

Directly the contrary principle was exhibited in other Roman buildings, as for instance the Baths, The Basilicas and elsewhere. Nearly all were buildings of practically one story with one great "order" in their height, vaulted roofs of course, adding to the height, and most buildings also possessed a basement or "socle". The Coliseum, again by the superposition of "orders" outside, belied the interior which of course was practically in "one story," or one great enclosure; though without roof, (unless the awning or "velarium" be so considered.) One would have expected the outside wall to have been designed with one great order, with the landings of the stairways or inclines marked out merely by belt courses or arches.

Would it not have been equally logical to have designed tiers of orders upon the outer walls of Basilicas or Baths when no corresponding floors existed on the interior? The mere fact of stairs or inclines being required to reach the seats in the Coliseum would not warrant the division of the outer wall into stories.

This reasoning would also apply to the arched construction, without reference to the tiers of orders, for there is to be seen an arcuated style of building developed in the Roman aquducts and bridges generally without the accompaniment of the orders.

A Triumphal Arch, or the modern "Arc de Triumphe" would appear absurd if designed with tiers of "small orders."

To come down to modern work: How would an ancient architect regard our modern buildings of fifteen or twenty stories if he could be brought back to the world to view them?

We do not usually remember, unless our attention is specially called to it, that almost all ancient buildings, whether religious or secular, were build practically in *one story*, in the case of the Greek temples the lighting being upon the "hypœthral" system, or from the roof, in almost all such buildings there is but one tier or range of windows at most, these being placed usually, at a height above the ground or floor.

It is of course only necessary to mention the Egyptian and Greek temples, or the Indian Rock Cut Temples. Most buildings of India, China or Japan which are ancient, also present the same characteristic of an interior practically in one apartment or story, any horizontal divisions into stories or stages being either avoided, or if required being subordinated so as not to affect the general design.

In ancient temples this is especially noteworthy. The restorations of Solomon's Temple and of the Parthenon show the acceptance of this idea, as if it were an inherent characteristic of such buildings.

Again in modern work: The Paris Exhibition buildings and World's Fair structures were nearly all in one height, i. e., one story.

To turn to domestic building, as noted above, the Roman and Pompeiian and Grecian dwellings were arranged in suites of spacious apartments, rarely, except for subordinate rooms, in more than one story. It is only necessary to refer to the writings of Viollet-de-Duc and others to verify this. The examples of domestic building shown at the Paris Exhibition of 1889 also in general bear out the same argument. The houses in Oriental cities and the pueblo dwellings of Mexico show a flat roof system with one, though sometimes two stories; the roof being used as a sleeping place in warm weather, or as a place of security in case of attack.

In viewing the past, one cannot help thinking that those who look upon our modern city buildings as "great monuments," "marking an epoch," constituting a real "new departure" or "new era," "the like of which never has been seen," etc. etc., must be gifted with a very modern pair of spectacles; and there are a few in whom the reverence for and admiration of the ancient examples of architecture is not yet extinct, who cannot join in the extravagant praise occorded by some contemporary writers and critics, to this phase of our city architecture. To inquire futher how the ancient types of architecture have influenced those derived from them, that is, The Medæval, The Rennaissance, and modern styles.

Ferguson gives a large share of praise to those works of the Rennaissance, most of them in the classic or Rennaissance styles, which exhibit the feature of a single large order for the whole height, whether this is used upon the exterior only or in the interior also. In these the successive stories though subordinated, are not however ignored, but given a special and appropriate treatment of their own.

It is obvious that this classification includes those structures which in design are termed "astylar," or without a specially devised scheme of orders, columns and pilasters. Such were the Florentine Palaces; and some other examples.

It is obvious of course, that the introduction of a basement, podium, or socle, an attic or a higher or lower roof, gave opportunity for a variation in proportion.

In Medieval architecture it may be noticed that the best examples of cathedrals are designed like ancient temples, in practically one height or one large apartment, the division of their height into triforium, clerestory, etc., being merely accidental, and subordinated to the general effect. This is shown by the continuation of the vaulting shafts, or in early examples, of piers, rising from floor to roof.

In Medieval castles also, we may remark that there seems to have been a dislike to exhibit the interior division in stories or stages upon the outside, the walls having usually only loop-holes, and presenting a generally blank surface, a sheer height from ground to cornice. It was not until the Renaissance, the fifteenth century, that these walls and towers began to exhibit the internal arrangements by a scheme of applied architecture, pilasters arches, etc. Thus in France especially we notice the cutting up of such buildings into stories by orders of small pilasters and string courses, though several stories were often made to appear as one by the continuation of the vertical lines, an instance of this being in the staircase at Blois, where the pilasters run from ground to roof, the sloping lines of the staircase abutting against them behind; while the landings or stories are virtually ignored; thus being exactly the reverse of that adopted in the Roman Coliseum, which makes a division into stories where they virtually do not exist, the interior consisting of one range of seats from bottom to top.

The intention, in thus enumerating examples, is to call attention, to the special characteristic of modern architecture, as contrasted with that of former periods: That it consists largely of buildings composed of *strata or layers*, instead of being in one story. This is a peculiarity often overlooked.

Seeking other examples in modern architecture and taking Paris as the acknowledged center:

It will be allowed that the most successful buildings there, those which have received most praise, are those in which the principle enunciated here has been fully and completely adopted. Not to mention those structures modeled after the works of Greece and Rome, some of the more modern works will serve to illustrate the doctrine equally well. As a contrast to recent examples of high buildings, for instance: The Arc de Triumphe; The Station du Nord; The Palace de Justice; The Library of Saint Genevieve, and others.

The necessity of building twenty stories eight or ten feet high, one above another, does not compel us to recognize each one in a design striped horizontally "zebra fashion." A new York architect recently propounded a scheme for a "revived Greek style" in which this programme was apparently advocated.

Let us suppose that it is desired to make out the best possible case for the modern "high-building." If as some writers assert the necessity for the construction of vast "rookeries" is necessary and that they form an important adjuct of modern "civilization," that they are indispensable to modern "business methods;" that they are "signs of the times," etc., does this in any way make them more "admirable as works of architecture?" should we be obliged to make all our received ideas upon architectural style and proportion conform to the limitations imposed in carrying out works of this kind, and the "dictates" of real estate operators and owners?

These are questions which have been asked more than once by both architectural authorities and "laymen" and it seems high time that a general concensus of opinion was arrived at.

As matters stand at present, there seems to be no criterion in this department of design, each worker being a "law unto himself."

Possibly there may be some changes near at hand in our social or commercial organization which would influence popular opinion upon these subjects, leading to a modification of received ideas; and "the traditions of business." Such would be for instance, changes in the real estate value prevailing in our cities, and a more uniform distribution of the best "investment property," so called. This might result from the adoption of improved methods of "transit" in cities; for both passenger and freight.

As to the rather extravagant pretensions made by the votaries of "high building." There are many, authorities critics and writers, who continue to hold different opinions. They may do so fairly, having on their side the evidence derived from scientific demonstration, also from commonsense reasoning, and from the greatly superior results secured in Europe, by enforcement of building regulations.

Those who wish for real "advancement" in architecture in this country contrive to lament that so small an area of "this goodly frame the earth" has been allotted to those charged with the administering of our urban architecture.

It is not at all improbable that the improved transit methods referred to, and changes in the distribution of business and population, may make an end of the high building "fad;" a resultant of the present system (or lack of system) of real estate valuation. Some of the French journals have from time to time published accounts of the "high building industry" of this country; speaking of some examples as "*les grandes batisses*" of America. It is not easy to believe that these works are thought worthy of praise by foreign critics. They are probably commented upon as "novelties".

It is said that high building "must go on," etc. Now supposing that the whole southern end of the city of New York were to be covered with "high building" what would be the result. Neither sunlight nor fresh air could penetrate the fastnesses and recesses of the small areas left unoccupied. It would become a "City of Dreadful Night" for artificial lighting would become imperative.

It is well at times to look ahead a little and anticipate the trend of popular ideas, hailing eagerly any of the straws which may serve to show the drift of opinion and enable us to forecast new developments at the beginning of the coming century.

THE LEGAL STATUS OF THE PENNSYLVANIA CAPITOL COMPETITION.

OUR READERS will be interested in the following continued text of the opinion of Judge Simonton, of the Court of Common Pleas of Dauphin County, Pa., sustaining the demurrer of four of the five State Capitol Commissioners and dissolving the temporary injunction in the equity proceedings brought by Messrs. Cope & Stewardson, of Philadelphia, and Alden & Harlow, of Pittsburg.

CONTINUED FROM LAST NUMBER.

On the other hand, in paragraph one of part three it is stated that "the problem before the Commissioners is therefore one of securing a general scheme for the arrangement and design of a group of Capitol buildings, in order that the new legislative building, in its arrangement, location and architectural character, may bear a convenient and harmonious relation to a complete system of which it will eventually form a part." And in paragraph two of the same part it is stated that "the problem to which the attention of architects is invited is therefore that of a general design, comprehending the legislative and several departmental structures in addition to the present Executive Building. Such design must permit the erection of a new legislative building without disturbance to either of the old departmental buildings, must accept the executive Building and the proposed Hartranft monument as fixed elements of the design and must not exceed certain limitations of cost."

And in paragraph 35 of part two, it is stated that "upon the appointment of said architect all designs not accepted will be returned forthwith at the expense of the State to their authors, and the names of those not among the authors of the eight designs selected by the Board of Experts will be publicly announced, and no use will be made of any of the drawings not accepted, nor of anything contained in them which is original as to this competition, except by written permission of its author and on payment of proper compensation therefore as determined by the Board of Experts." And section 36 declares that "none of the unaccepted drawings will be exhibited to the public or to any competitor without the written permission of its author."

These and other provisions of the programme which might be quoted certainly tend to give weight to the argument that the primary purpose of the competition was to procure plans for the Capitol buildings, coupled with the provision that the author of the plans accepted should be employed as the architect to carry them into execution.

ARCHITECTURAL COMPETITION CRITICISED.

We find it very hard to believe that this Board of Commissioners would have understandingly adopted the elaborate scheme contained in the programme for the sole purpose of selecting an architect. We do not believe that any business man of ordinary discretion about to expend the sum of $550,000 immediately, and perhaps twice that amount prospectively, would select and employ an architect to prepare plans and supervise the erection of buildings to cost that amount without ever having seen him, without any knowledge whatever of his character, his habits, his executive ability, or his pecuniary responsibility, or any other knowledge of his fitness, except that to be acquired from inspecting a plan for the buildings drawn by him. Yet this is what the Commissioners must have agreed and intended to do if the sole purpose of the competition in question was to determine the selection and employment of an architect.

The programme itself recognizes the unquestionable fact that the result of such a method of selecting an architect might be the selection of one would be "an unsuitable person to be placed in charge of this work;" and it attempts to remedy the evil of such a result by providing that in that event the architect employed "shall at the request of the Commissioners associate with himself in the performance of his duties an architect who shall be acceptable to the Commissioners. And such associated architect shall be paid a portion of the fee provided herein to be paid to such appointed architect, such portion to be as agreed upon by both architects, or in the event of their failure to agree, then as fixed by the Board of Experts." In that event the outcome of the scheme would be, that the Commissioners would have employed as their principal architect "an unsuitable person to be placed in charge of the work," and would have associated with him another architect whose compensation they could not fix. And if this were done there would certainly be danger, which no prudent man would willingly encounter, that this architect and the chief architect, being an unsuitable person, would not act in harmony in carrying on the business. For these and other reasons which might be stated, we think, if the sole purpose of this scheme was the selection of an architect, it is unfortunate that it was ever adopted by the Commissioners.

DELEGATING DISCRETION TO EXPERTS.

But in the view we take of the case, it is not necessary to determine what was the primary and what the secondary purpose of the competition. It was certainly, in some order, designed to secure both an architect and a plan. But the fundamental question, in our opinion, is whether the Commissioners have, by any of the provisions of the programme, delegated to the Board of Experts the right, in whole or in part, to control their discretion, either in the selection of the architect, whom the act requires them to employ, or in the selection of plans for the buildings.

We understand it to be conceded by the counsel for plaintiffs that the Commissioners could not delegate to the Board of Experts, or to any other person or persons, any discretion committed to them by the act, with respect to the selection and employment of an architect, or the adoption of a plan; and whether we are right in so understanding, or not, there can be no doubt that this is the law. But counsel contend that the Commissioners have not done this. They refer us for their position on this question to the opinion of the learned Attorney General reported in 6 District R. 597, wherein he says: "There is no limitation upon the powers of the Commission found in the act of Assembly, in the selection of an architect. They conld have selected one, if they had so chosen, to do the work without competition. They choose, however, to exercise their discretion for what they believe to be the best interests of the Commonwealth, and invited all architects to exhibit their shill. The Commissioners all being laymen, and architecture being a science with which they were not familiar, they ask the Board of Experts to determine the ability of the architect from the design he submitted. Of this all competitors were fully advised, and there can be no reasonable ground of complaint. I therefore conclude, first, that the Commissioners, neither in paragraph 11 of part one nor else where in the programme, have abdicated, as such Commissioners, or delegated to others, the power vested in them; second, that it is the duty of the Commissioners to select as architect of the new capitol building the author of one of the eight designs reported by the Board of Experts as exhibiting the best talent."

This is a clear and concise statement, and does not make it the duty of the Commissioners, on behalf of the plaintiffs. But we regret that after the most careful consideration, we are unable to concur in this conclusion.

ALL DESIGNS MUST BE CONSIDERED BY COMMISSIONERS.

It will be conceded that the act itself does not make it the duty of the Commissioners to select an architect from the eight recommended by the Board of Experts. Guided by the act alone, it would be their duty to select and employ, from all the architects available, the one whom they believe the best for their purpose. It is now their duty to select one of the eight; the range of their discretion has at least been much circumscribed. And this has been done, not by a process of exclusion carried on by themselves, but by a Board of Experts, to whom they have delegated the power to exclude. The learned Attorney-General says: "They ask the Board of Experts to determine the ability of the architect from the design he submitted," and he decides "that it is the duty of the Commissioners to select an architect of the new Capitol building the author of one of the eight designs reported by the Boark of Experts as exhibiting the best talent." But if it be their duty to select one of eight thus nominated by the Board of Experts, they have certainly precluded themselves from exercising an independent judgment and from giving only the weight to the opinion of the experts, to which, in the exercise of their sound judgment and discretion, they may think it entitled.

It will be seen by a reference to paragraph four of part two that the Commissioners have had nothing whatever to do with the selection of a majority of this Board of Experts. The Commissioners selected one. The second was selected by a majority of the six architects asked to compete, and the third was selected by the first and second. The result is, that instead of exercising the discretion given to them in the act to "advise with and employ an architect or architects," the only discretion which the Commissioners retained was to select and employ one of eight propounded to them by a board of experts not selected by the Commissioners, when there were thirty seeking the employment. We are wholly unable to see how it can be even plausibly argued that this does not imply a delegation or surrender of their discretion.

It is true, as it is said by the Attorney General, that, "there is no limitation found in the act of Assembly upon the powers of the Commission in the selection of an architect." It rests in their discretion to determine what information and advice they will obtain, and how they will obtain it, to assist them in making a selection. As is said in Lyon vs. Jerome, above cited, at page 495: "In cases of authority to represent private individuals, the person thus entrusted may have occasion to depend upon scientific or professional advice for the guidance of his own judgment. He may even, in matters out of the scope of his own information, rely entirely upon the authority of his adviser or assistant, yet he is still bound to form a judgment for himself and to assume its responsibility." *He cannot contract in advance that he will adopt the advice of his counselor and thus abdicate his own judgment instead of exercising it.*

The application of the principle does not depend upon the proportion of the discretionary power which is delegated or surrendered. If the Commissioners may agree that they will surrender their discretion and decline to consider the availability of 22 out of 30 architects and plans submitted, it certainly cannot be said that they could not snrrender it as to 26, and if as to 26, then certainly as to 28; yet in that case no one would, we think, contend that they had not limited or circumscribed the discretion vested in them by the express terms of the act.

Counsel contend that the Commissioners exercise the discretion committed to them by the act when they provided for the selection of the Board of Experts in the manner prescribed in the programme, and practically confided to them the selection of the architect. We cannot see the force of this argument. The discretion vested in them is to "advise with and employ an architect," not to determine the manner in which they will bind themselves to employ one named by others.

CANNOT DELEGATE DISCRETION.

It can hardly be necessary to cite authorities to show that the Commissioners cannot delegate to others the discretion vested in them by the act. We refer, however, to a few cases of the many which may be found which declare this to be a well established principle.

In Lyon vs. Jerome, 26 Wend. 485, already cited, the Court, construing an act of the Legislature decided that the authority conferred by the act upon canal commissioners to enter upon and take possession of the land of individuals for the construction of a canal, could be executed only by the Commissioners in person or under their express direction; and that an engineer or any other sub-agent of the State could not lawfully exercise such power except by their express direction, although the construction of the canal in the vicinity of the premises entered upon had been confided to the engineer. Senator Verplanck, delivering the opinion of the Court, said: "The language of the statute, as well as the nature of the trust itself, shows that this is an authority confined to the judgment and discretion of the Commissioners themselves, for the impartial discharge of which they are responsible to the State." And in conclusion he said: "I have only to add that it is of the greatest public importance to establish the general rule of agency, that delegated authority cannot be delegated again without special power so to do as governing the official powers, acts and contracts of our State officers."

In State vs. City of Paterson, 34 N. J. L. 167, it appeared that the charter of the city provided "that the mayor and aldermen of the city of Paterson are hereby authorized and empowered to purchase a city hall or other buildings, or to purchase a suitable site or sites and erect thereon one or more public markets, city hall or other public buildings, and to employ suitable architects, engineers and other persons necessary to accomplish the purpose hereby contemplated, and to pass all such ordinances, rules, regulations and by-laws for the establishment, maintenance, using, renting and governing said markets, city hall or other public buildings as they may deem proper."

The Board of Aldermen of the city, intending to put in effect the provisions of this and other sections of their charter, passed a resolution appointing three commissioners "to proceed in the premises according to law" and purchase a site and build a public market thereon." The power of the mayor and aldermen to appoint this commission being contested, the Court said: "The mayor and aldermen are to purchase a suitable site or sites and erect thereon one or

more public markets, and to employ suitable architects, engineers and other persons necessary to accomplish these purposes. They are therefore required to use judgment and discretion in determining the suitableness of the site, and also of the architects, engineer and other persons employed to accomplish the purpose. This they must use and cannot delegate to others without express legislative authority."

In Birdsall vs. Clark, 73 N. Y. 73 (29 Am. Rep. 105), where it was provided by a city charter that the sidewalks should be built and maintained at the expense of the adjacent owners, and that when the common council should order work thereon and notify the owners thereof, if it was not done within the specified time the common council should by contract or otherwise cause it to be done. The common council directed the superintendent of streets, by resolution, to cause such work to be done when the owners neglected to do so. The plaintiff brought an action to enjoin the superintendent from doing such work in front of the plaintiff's premises. The Court held that the action was maintainable; that the power conferred by the charter, involving the exercise of discretion as to the time and manner of the performance of the work, must be pursued by the council and could not be delegated. And several cases are cited in the note at the end of this case in the American Reports.

Several other questions were argued by the counsel, which it would be necessary to consider if the view which we have taken above was not decisive of the case, but as it is we shall not discuss them.

CONCLUSION.

It will of course be understood that we are concerned with the legal questions only and have nothing to do with, and express no opinion upon, the propriety of the action, professional or other, of either or any of the parties to this controversy.

We sustain the demurrer on the ground that the Commission provided for by the act of April 14, 1897, is a delibrative body invested with discretionary powers in respect to the selection of an architect and the adoption of plans for a new Capitol building; that the terms of the programme referred to in plaintiff's bill, if enforced, would limit the discretion and the duty to exercise their independent judgment committed to, and imposed upon them by the act, and therefore a court of equity will not enforce these provisions of the programme. The demurrer is therefore sustained and the bill is dismissed at the costs of the complainants.—*J. W. Simonton, P. J., in the Engineering Record.*

SHORT SERMONS.

WOE unto him that buildeth his house by unrighteousnes, and his chambers by injustice; that useth his neighbor's service without wages and giveth him not his hire; that saith, I will build me a wide house and spacious chambers, and cutteth him out windows; and it is ceiled with cedar, and painted with vermilion. Shalt thou reign, because thou strivest to excel in cedar?—*Ancient Hebrew Writings.*

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

THE residence of Capt. Thomas Mein, designed by William Mooser & Son of San Francisco has been recently completed in Oakland. This building is in the old Colonial style and is situated on the south east corner of Jackson and Lake streets on a lot 100 by 150 feet in size, and consists of two stories, basement and attic. The basement is of brick with five feet of sandstone above the ground, the main walls of the building being covered with narrow clapboards. The front entrance is reached by a flight of marble steps leading to a portico supported by columns; the floors of portico and vestibule being of mosaic. The building is heated by hot water.

The main hall is circular in form, twenty-two feet in diameter the ceiling being arched and supported by a peristyle of eight columns—the space between the arches of the ceiling are ornamented with stucco work. The floor of the main hall is laid with narrow tongue and grooved Mahogany with a wide circular border of parquetry. The stairway, posts and rails are of mahogany, and the balustrades are finished in ivory and gold, the hall hardware being dull brass.

The main stair to second story winds around the hall; the second landing forming a balcony extending into the hall and above this balcony the second story is opened, allowing a view of the ceiling light or dome on the second story ceiling.

Under the balcony there is a large corner fireplace made out of large slabs of Mono County marble and the mantle is of carved Mahogany, circular in form.

The dining-room, drawing-room, library and small hall to billard-room open from the main hall, so when the folding doors are open the whole of the main story can be thrown together making one large room.

The hall, stairway and second story hall are wainscoted to a height of five feet with ornamental panels and all the doors made to match. The walls are in blue and the woodwork in ivory and old gold; the drawing-room is twenty feet by thirty-four feet long, the fire place being surrounded with a large old Colonial onyx mantle.

The walls are in blue with fleur de lis ornaments and the woodwork finished in old ivory and bright gold with decorated cove and ceiling, the hardware being gilt.

The billiard-room is finished in quartered sawed Eastern White Oak, finished natural, wainscoted to a height of five feet four inches with flush panels and key blocks.

The mantel pieces, wash basins, etc., form a projecting

ENTRANCE OF CAPT. THOMAS MEIN'S RESIDENCE, OAKLAND.
WM. MOOSER & SON ARCHITECTS.

hood with carved oak brackets supporting the same; the hardware in this room is of antique silver. Off this room and leading to outside rear entrance is the toilet.

The dining-room is oval shaped with large shallow coved ceiling—this room has five large windows, taking up the entire end of room, the size of room is 20x30 feet, and has high wainscot of flush panels with flush key blocks, the China dresser and glass one on each side of the room are made the same shape as the room, the glass one has mirrors on back and side, with plate glass doors and shelves and silver plated brackets, fastenings, etc., the finish of this room is quartered sawed oak Flemish finish.

The library, including mantles, bookcases, etc., are of Mahogany, the hardware in silver.

Both dining-room and billiard-room floor are finished in quartered sawed tongue and grooved narrow Oak boards highly polished.

Between the dining-room and kitchen is the butler's pantry fitted up with all modern appliances, sinks, etc.

The kitchen is fitted up with one of the large latest improven ranges, with hood, etc., and with large sinks and drainboards, there is also a pantry adjoining fitted up with boxes, shelves, bins, marble pastry boards, safes, etc., etc., all completed. Adjoining this is a servants' dining-room.

The second story consists of one chamber having bath and toilets attached, and four other chambers, besides linen closets, housemaids' closets, baths, toilets, etc., etc.

All bathrooms and toilets have open plumbing and the walls are tiled in ivory color and the floors laid in Parquetry.

In the attic there are four chambers, bath; toilet, etc., also a large room all finished in tongue and grooved boards, polished, including the floor.

The basement is fitted up for room for servant, wine cellar, vegetable room, with sinks and marble drainboards, store-rooms, coal and wood-room, heater-room, laundry, etc.

The stable is provided with all the latest improved appliances, space for three stalls and one box stall, with harness-room, man's room, etc. Finished in tongue and grooved redwood boards in colors—floor is cement and stalls lined with wood.

The house stands almost in the centre of the lot, leaving ample space all around for garden and cement walks.

BUILDERS OF THE COMMONWEALTH

The principal contractors were Messrs. Campbell & Pettus whose mills and wood working establishment is located on Brannan street between 4th and 5th. The house itself is the best evidence that they performed their share of the work as per contract.

In the main portion of the house all the hardware is Art Metal work of The Yale and Town Manufacturing Company of Bonn design and is known to all architects for its correctness of design and unrivaled collection of Ornamentations.

The switches and push buttons were made to match the hardware by the same company and fitted with Harts Patent Switches.

The Dunham, Carrigan Hayden Company supplied all of these goods and that is a sufficient guarantee that they will last as long as the building does—and by the way, that Old Colonial Knocker as shown in our illustration of the main entrance is a work of art in itself.

To most of those who read these pages, Orsi is known, if known at all—as a painter of ability and a designer of original invention. By reference to the illustrations and the foregoing description of the interior it will be seen that his method of producing Ivory effects and his color work is unusual and interesting. Mr. Orsi has never done a better piece of work and the finished result is wonderfully rich, suave, toned and harmonious, transferring in every detail the conception of the architect—622 Washington street, is the habitat of the only Orsi.

For the plumbing and heating work Henry Williamson, the well known Sutter Street Plumber had the contract. Mr. Williamson fitted the house throughout with the "Lilly" closets, from the works of the John Douglass Company and these closets have well earned the credit mark of "another advance in sanitary science." This company is represented on the Coast by Mr. E. M. Douglass with store and offices at 208 Ellis Street.

The tiling throughout the house together with the mantels shown in our illustrations of the interior, were furnished by Messrs. Mangrum & Otter of 27 New Montgomery street.

The wood mantels throughout are in themselves works of rare merit both in design and finish and reflect much credit on the contractors.

The Lavatory fittings and wash basins complete, except the marble work, as also all of the little nickle plated conveniences in the bath and toilet rooms were of the exclusive design order of which the J. L. Mott Iron Works are the manufacturers and M. S. James Flood Building the Pacific Coast representative.

The Waterproof and insulating properties of the building are much enhanced through the fact that it is lined throughout with the P. & B. Building Paper.

The Paraffine Paint Company of 116 Battery Street are the manufacturers of this well known make of paper.

The Marble work of which our illustration of the main entrance is a good example was done by Joseph Musto & Son whose yards and finishing works are at 710 Battery street.

The well known and always trustworthy house of John G. Ils & Co., of 814 Kearny street, supplied the kitchen and laundry outfit, which included one of their large, latest improved Cooking Ranges.

ONE of our illustrations this month is the new Union Depot being erected at Mill Valley for the use of the North Pacific Coast Railroad and the Mill Valley and Mount Tamalpais Scenic Railway. The former has the principal interest in the new structure. The station proper is twenty-two feet by seventy-two feet within which limits are included waiting rooms, baggage rooms, ticket office and Wells Fargo's office, two toilet rooms etc.

On the second floor there will be apartments for the station agent with all necessary accomodations.

The entire lower story will be finished in polished redwood. At either end of the waiting room will be two very large Roman brick fireplaces. The train shed is to be 50x150 feet covered with a trussed roof in one span, and so arranged that all passengers can change from one train to the other without leaving the shelter of the shed. The train shed is to be planked throughout and the northern end devoted to the office for the Scenic Railway.

Both these railroads traverse a very picturesque region—

the road up Mount Tamalpais winds through canyons and along the southern slope of the mountains and is well protected from the trade winds. The views to be enjoyed on the trip are alone worth a trip to California to see. The The surrounding hills and Saucelito in the foreground, the Bay of San Francisco and the city by the Golden Gate in the distance combine to make a shifting panorama that long remains in the memory.

It is by the North Pacific Coast Railway that San Rafael is reached, one of the most charming residence towns in the State, and a favorite resort of the elite of San Francisco. The roads extends from there northerly past summer resorts, camping grounds, farms and villiages until at last the Russian river, Duncan's Mills and Cazadero are reached where the majestic redwood trees still stand in closed ranks waiting the woodman's ax. Popular excursions are run during the summer months allowing the sight seer to obtain in a few hours as much enjoyment as can be compressed into a single day, while those who have more time at their disposal and a keen appreciation of the beauties of nature can indulge their taste to the fullest extend, camping, boating, hunting, fishing, swimming and in a hundred other ways enjoy the glow of health resulting from these sturdy out door exercises.

THE CONTRACTORS

The principal contract on the Depot was awarded to Thos. O'Connor of San Rafael. Mr. O'Connor is now as he has been for some years past the principal contractor and house builder of Marin County and is one of those earnest and trustworthy workers who always lives up to his contracts and who can at all times be relied upon to carry out the specifications to the letter.

Every reader of this paper knows that *Multum in Parvo* is the familiar watchword of Mr. Jas. A. Wilson—to whom the brick work was awarded, which fact carries with it that other fact that there's enough said.

The plumbing and lighting work went to Mr. S. M. Burt of Eastland and Mill Valley, and the dwellers of these hillside health retreats are fortunate in one respect if in no other—viz.: In having a plumber always in their midst—for a plumber, like a doctor is "muchly" needed when wanted.

Van Dorn's Steel Joist Hangers will be used throughout the building and it goes without saying that these "Hangers" have no equal.

POINTS ON PRACTICAL WORK.

WHERE is quite generally a false idea prevailing among mechanics (stone masons and stone cutters) in regard to the proper method in which square dressed rubble, or broken ashlar, should be arranged, says *Stone*, and this mistaken idea seems to have originated from the fact that architects' specifications and instructions in contracts for such class of work usually specify that stones not under five (5) inches or over fifteen (15) in height shall be used. Sometimes other dimensions are given, as for instance not under four (4) or over twelve (12) inches, although it seldom happens that any dimensions as to length are given.

As a matter of fact, no such fixed rule is possible in practice, and should the mason hold strictly to certain sizes it would simply reduce the work to dimension stone and thereby add unnecessary cost without any additional beauty to the appearance of the work.

To prepare stone most economically for this class of work —square dressed rubble or broken ashlar—it should be cut in the quarry whenever possible, thereby saving freight or hauling on a large amount of refuse or spawls, and sizes should be from say four (4) to eighteen (18) inches in height or whatever the stones will make without too much waste. It is not at all necessary that the stones should be exactly four, eight, twelve or sixteen inches. Larger than eighteen inches, however, in majority of cases should not be used, although even over this size might be utilized without detracting from the appearance of the work, if, as sometimes happens, such sizes could be used in a wall with large surface, and unbroken by openings. By having the stone delivered on the job, cut and ready to go in the wall, the work can be pushed along very rapidly, and the fitter, or even the mason, can quickly arrange the proper breaks in the courses, and easily make the necessary closures from either the cut or the other stone on the ground.

The place of evey stone as well as the bond was arranged by the writer, he on the ground measuring and sending the stones to the masons to be placed as directed. Two masons set them in place as fast as they could be set up. This was a departure from the ordinary methods of doing this class of work and gave entire satisfaction to contractors and architects. Where broken ashlar is used and there is a great deal of dead work such as invariably exists in churches and public buildings, stones of larger dimensions ccn be used and give to the work a much handsomer appearance to have them properly mixed with the smaller stones, necessitating, however, an increase in length of bed joints.

NOTICE TO ARCHITECTS.

Office of State Normal School of San Diego, San Diego, Cal.

December 16, 1897.

TO ALL ARCHITECTS WHOM THIS MAY CONCERN:

The Board of Trustees of the State Normal School of San Diego, California, hereby invite the submission of plans and specifications in detail for a two-story and basement brick building, to be erected upon the "College Campus" site on University Heights, in the City of San Diego, for the use of said Normal School, to cost when completed not to exceed $100,000.00; provided, however, said plans and specifications must be so prepared, that a portion or section of said building can be properly constructed at once, at a cost not to exceed $35,000.00, and in such a manner as to permit additions to be made thereto.

The Architect whose plans shall be accepted and adopted, shall receive as a premium therefor the sum of $500.00; provided the Board of Trustees reserve the right to accept or reject any or all plans submitted, without incurring any liability to any Architect or person for any plan made or submitted.

The plans and specifications must be delivered to said Board of Trustees, at the Law Offices of W. R. Guy, in San Diego, Cal., on or before the 19th day of January, 1898.

Architects competing are referred to J. L. Dryden, Secretary, at San Diego, for further particulars.

By authority of the Board of Trustees of the State Normal School of San Diego.

J. L. DRYDEN, Secretary. W. R. Guy, President Board of Trustee.

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street,

SETH BABSON, Pres. H. A. SCHULTZ, Vice-Pres.
OLIVER EVERETT, Sec. JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

THEO. A. EISEN, PRES. ARTHUR B. BENTON, Vice-Pres.
WILLIAM C. AIKEN, Sec't. AUGUST WACKERBARTH, Treas.

WASHINGTON CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

JOS. C. HORNBLOWER, Pres. JAS. G. HILL, Vice-Pres.
E. W. DUNN, JR., Sec. W. J. MARSH, Treas.

ASSOCIATION OF ARCHITECTS OF ARIZONA, meetings held at Phoenix, Arizona.

D. W. MILLARD, Pres. T. H. MADDOX, Vice-Pres.
W. R. NORTON, Sec. and Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.

E. J. MOLERA, Pres. W. F. C. HASSON, Vice-Pres.
OTTO VON GELDERN, Sec. EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.

JAS. E. BRITT, Pres. J. L. E. Firman, Sec.

BUILDERS' EXCHANGE, Directors meet first Friday in each month at Mission and New Montgomery.

S. H. KENT, Pres. JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday evening of each month.

ADAM BECK, Pres. M. V. BRADY, Sec.

BOOKS AND PERIODICALS.

Journal of the WESTERN SOCIETY OF ENGINEERS for October, 1897. The leading article in this journal on "Motocycles" read September 8, 1897, for the purpose of developing a discussion on Motocycles, in the furtherance of a more general interest and wider dissemination of information on the subject, which would be conductive to the earlier utility of this mode of transportation for commercial uses, and pleasure as well, the Electrical Committee of the Western Society of Engineers, consisting of Messrs. H. M. Brinckerhoff, L. L. Summers and Bion J. Arnold, formulated a circular outlining the following general divisions of the subject for consideration:

1. Preference as to driving power with reason as to selection. 2. Economy. 3. Control. 4. Convenience. 5. Design and construction. 6. Safety and reliability. 7. Field of application. 8. Limiting conditions.

The answers to this circular are given containing much information on this subject.

THE STRENGTH OF MATERIALS. A text book for Manual Training Schools, by Mansfield Merriman, Professor of Civil Engineering in Lehigh University, first edition. Published in New York by John Wiley & Sons; London: Chapman & Hall, 1897. Professor Merriman is the author of several works that have served as text books in many schools and colleges among others A Treatise on Hydraulics, A Handbook for Surveyors, Higher Mathematics, etc. Professor Merriman appears to have a very happy faculty of making his meaning understood with few words; an example of this may be seen in the first chapter under the head of "Elastic and Ultimate Strength."

This book cannot fail to recommend itself to Engineers and Architects but also prove of great value to students in those branches.

LIPPINCOTT'S Monthly Magazine for December, 1897, has for a complete novel "Poor Chola" by Julia P. Dabney. This novel is somewhat out of the common track and describes localities not much known to the general reader, but nevertheless will be considered interesting by many readers. Among other articles of interest "Gold Mining in North America" by George Ethelbert Walsh, reflects the interest now taken by the world in gold mining: if this rage continues, the silver question settles itself by becoming more scarce than gold. To the question "Who are the Greeks?" the reply might be made that it matters not.

THE ARCHITECTS DIRECTORY for 1897-98, published by William T. Comstock, New York: price one dollar. It is always a welcome volume containing as it does a list of the Architects in the United States and Canada, classified by States and towns with the architectural associa-

tions to which they belong indicated against each name. Prepared with the greatest care to secure accuracy both in names and location.

It has also a classified Index of prominent dealers and manufacturers of building materials and appliances. Architects should be thankful to Mr. Comstock for this carefully prepared annual edition now in its fourth year, while to dealers in building materials it is a perfect God send.

THE UNIVERSAL CARPENTER AND JOINER, and Wood Workers Assistant, by Fred. T. Hodgson, published by the Industrial Publication Company, 10 Thomas street, New York. In five parts, the first part with 250 illustrations, Royal 8 vo. bound in stiff cover $1.00.

Mr. Hodgson was formerly a contributor to this journal and well known as the author of "The Steel Square and its Uses," as well as various other volumes on "Practical Carpentry," "Stairbuilding Made Easy," etc.

The aim of the Author is to make the above work the most complete treatise on Carpentry and Joinery published to date, and the publishers have no hesitation in saying that the success which Mr. Hodgson has achieved during the past twenty years in furnishing the mechanics of this country with thoroughly reliable and easily understood textbooks, is a sure guarantee of the excellence of his present effort.

It will be issued in Five Parts, each Part consisting of ouer 100 large royal octavo pages, printed on fine paper, and strongly bound in stiff paper covers; and as it is the intention of the publishers to place this important work within the reach of every industrious mechanic and apprentice in the land, they have placed the price at $1.00 per Part. Many works in the market, containing no more matter than a single Part, and not so well illustrated, are now selling for from $5.00 to $10.00 each.

A REMARKABLE CHURCH.

TO BE BUILT EXCLUSIVELY OF BRICK AND TERRA COTTA.

WHERE IS NOW in the course of construction in Chicago one of the handsomest and most substantial churches in this country, and when completed it will be a remarkable edifice. According to the Portsmouth (O.) *Sentinel*, it will be entirely of brick masonry. Even the window frames in which the glass will be set will be of brick. Erom floor to roofMoutside and inside, walls and ceilings, casements and stairways, the visible and the invisible—will be vitrified clay, depending on itself for support and decoration. The style of architecture is Romanesque and Gothic, after the style of the twelfth and thirteenth centuries. The total length will be 210 feet; width, 110 feet, with two two-towers thirty-two feet square at the bottom and 245 feet high from the sidewalk. The body of the church proper inside will be sixty-eight feet wide. In the erection of this church there will be no plaster, no stucco, no imitation marble, nor shams of any kind. Rev. Geo. D. Heldman, who is in charge, says that "a building consecrated to the teachings of the eternat truth should of itself be true," and as good brick is one of the most durable things in nature or art, he will let it bear witness to its own strength and beauty. The main entrance will be through six pairs of doors into three large vestibules leading directly into the nave and side aisles. The nave will be entirely free from columns. The side aisles will extend all around the church and behind the high altar. The height of the nave will be seventy-five feet; width, forty feet between the columns which divide it from the side aisles. The body of the church expands as the front is approached. They have some buildings of this style in Europe, but nothing of the kind has ever been attempted in this country, and it will be watched with a great deal of interest by those interested in the construction of large buildings.

In consequence of its being so novel, no brick suitable could be found in the market, and the builder had to have made to order the various shapes required. There will be no less than five hundred of these different kinds of bricks and moldings. Terra cotta will be used extensively, both inside and out, from the finials on the spires downward. White terra cotta figures of religious subjects will decorate the interior. The altars, communion rail, front of organ loft and pulpit will all be of terra cotta.

About 2,500,000 brick will be required in its construction, of which about 500,000 will be of fancy moldings. The prevailing color of the brick will be of light buff, with warmer colors for trimmings, running into dark brown. The body of the walls will be of light buff and yellow. The ribs of the arches and groins will be of molded bricks, the keystones of terra cotta. Not a foot of wood nor a yard of plaster will be used in the whole building. The brick casements will have grooves into which the glass will be set and fixed with putty. The great amount of brick used in the construction of this remarkable building will be furnished by the Webster Fire Brick Co., of South Webster, O.

INFLUENCE OF LIGHT ON EDGE TOOLS.

IT IS not generally known that the light of the sun and the moon exercise a deleterious effect on edge tools. Knives, drills, scythes and sickles assume a blue color if they are exposed for some time to the light and heat of the sun; the sharp edge disappears, and the tool is rendered absolutely useless until it is retempered. Purchasers should, therefore be on their guard against buying tools from retail dealers and peddlers, which for show purposes have probably been exposed for days together to the glare of the sun. The unserviceableness of tools acquired under these conditions is generally wrongly attributed to bad material or to inferior workmanship. A similar prejudicial effect has been exercised by moonlight. An ordinary crosscut saw is asserted to have been put out of shape in a single night by exposure to the moon.

WANTED—TRUSTWORTHY AND ACTIVE GENTLEMEN or ladies to travel for responsible, established house. Monthly $65.00 and expenses. Position steady. Reference. Enclosed self-addressed stamped envelope.

The Dominion Company, Dept. V., Chicago.

BUSINESS MOSAICS.

The Pacific Coast representative of the J. L. Mott Iron Works Mr. M. S. James, can be found at his office 27 Flood Building. His show rooms are well worth a visit, the inspection of his stock of sanitary specialities will well repay the trouble.

The constant aim of this company appears to be the production of something new that at the same time is a little better than what has been produced. By reference to their advertisement in this journal a good idea of the various baths, lavatories, etc., can be obtained.

Messrs. N. & G. Taylor Co., Philadelphia, have lately furnished the largest Ventilator we have ever heard of. It has a total diameter of eighteen feet over all, the diameter of the neck being ten feet. It is on the Midland Beach Casino at Midland Beach, Staten Island. It is the "Pancoast" make which appears to be giving such great satisfaction throughout the United States. This same make of Ventilation was also used on the new Astoria Hotel, New York City.

Samples of "The Pancoast Ventilator" may be seen at the office of Mr. Charles J. Waterhouse, who represents Messrs. N. & G. Taylor Co. on the Pacific Coast, at No. 35 New Montgomery street, San Francisco.

The Pacific Loan Association sends us their 13th Annual Report for the year ending Dec. 1, 1897. The totals make up a very flattering showing and are as follows:

Receipts—$131,625.27. Disbursements—$131,625.27. Assets—$313,142.36. Of this $261,462.56 is in mortgage loans. Liabilities, including a reserve fund of $7,839.75. $313,142 36.

The securities in the hande of the Treasurer and the books of the association were examined and verified by the auditing committee, Messrs. I. S. Ackerman and E. Messager and found correct.

Mr. Emil Gunzburger the obliging Secretary of this and seven other Building and Loan Associations can be found by Builders and Architects—on the lookout for a loan—at 214 Pine street.

P. H. Jackson & Co., 228-230 First street and 7-9 Tehama street are the places to go if you want first class work in the way of fire and burglar proof arched and flat skylights, or patent water proof sidewalk doors and basement ventilators.

Mr. Jackson's long experience in this class of work makes him a first class authority for what is best in his line of business. The faithful manner in which his contracts are executed make it a pleasure to do business with the firm.

LEGAL DECISIONS.

From a large number of Legal Decisions of the higher Court, of the different States of the Union, we select and publish in this column, such as appear applicable to this section of the country.

OWNER ENTITLED TO EXPENSE OF CHANGING PLANS.—A lot owner who after notice that part of his lot was to be condemned, changed the plan of a building which he was erecting, so as to omit that portion of the lot to be condemned, is entitled to compensation for the expense so occasioned.

In re-Trustees Brooklyn Bridge, Sup. Ct. N. Y., 45 N. Y. Supp. Rep. 484.

MANUFACTURER BOUND BY STATEMENT OF AGENTS.—Statements of the agents of the seller of a range that owing to the peculiar construction of the range the pipes did not need to be insulated, are admissible as part of the transaction, in a suit to recover for the destruction of the house by fire originating from such lack of insulation.

Wrought-Iron Range Co. v. Graham, U. S. Cir. Ct. App., 80 Federal Rep. 474.

OWNER NOT LIABLE TO GARNISHMENT.—Where a building contract does not prevent the filing of valid liens against the building, though the owner have funds in hand, he is not liable to garnishment, but may retain such funds, and apply them to the discharge of mechanic's lien filed against the building.

Schotts v. Bell, 18 Pa. C. C. Sep. 427.

ARCHITECT HAS NO LIEN FOR PLANS IN MASSACHUSETTS.—An architect is not entided to a lien for drawing plans and specifications for a building, under the laws of Massachusetts (Pub. St. c. 191, sec. 1) which gives a lien to any person to whom a debt is

due for "labor performed or furnished and actually used in the erection of a building."

Michell v. Pankard, Sup. Jud. Ct. Mass., 47 Northeastern Rep. 113.

WHEN CONTRACTOR TAKES PRECEDENCE.—Where one advanced money to the owner of a building, and took a mortgage on same, while a contractor was erecting it, he is affected with notice of the contractors's lien, and the latter is not lost by reason of the contractor taking the notes of the owner secured by mortgage on the building.

F. & M. Nat'l Bank q. Taylor, Supreme Ct. Tex., 40 Southwestern, Rep. 966.

LIABILITY OF OWNER MAKING CHANGES TO TENANTS.—A tenant of the third and fourth floors of a building, whose water supply is cut off, furniture injured by dust and lime, ingress and egress interfered with, causing damage, by the landlords' repairing the second floor, may recover from the landlord for breach of covenant of quiet enjoyment, irrespective of his negligence.

McDowell v. Hyman, Supreme Conrt Cal, 48 Pacific Rep. 984.

WHEN WIFE IS NOT LIABLE FOR IMPROVEMENTS OF HUSBAND.—Where a husband agrees with his wife to erect improvements on her land, and to pay for the same, one selling lumber to the husband on his credit, and without intent to charge the wife for same, cannot enforce an equitable lien against the land.

Poe v. Ekert, Supreme Ct. Iowa, 71 Northwestern Rep. 579.

CITY BUILDING NEWS.

Alvarado near Hoffman. Cottage; owner, I. E. Laws; builder, J. Hegman; cost $1500.

Broderick near Grove. Two-story frame; owner, Mrs. Rosalia Altmayer; architect, J. E. Krafft; contractor, R. Currie; signed, Nov. 29; filed, Nov. 30; cost $4000.

Buchanan and Lily Ave. Two-story frame; owner, Ida M. Cummins; architect, Wm. T. Cummins; contractor, John Foster; signed, Nov. 18; filed, Nov. 27; cost $6784.

Buchanan and Lily Ave. Plumbing, etc; owner, Ida M. Cummins; architect, W. T. Cummins; contractors, Berarik & Spinks; signed, Nov. 26; filed, Dec. 2; cost $1216.

Buena Vista Ave. Two-story frame; owner, T. L. Henderson; architect, W. H. Lillie; contractor, T. T. Pottinger; signed, Nov. 18; filed, Nov. 19; cost $3835.

Capp near Adair. Cottage; owner, U. A. Hancock; architects, Havens & Toepke; contractor, C. A. Holm; signed, Nov. 13; filed, Nov. 16; cost $1500.

Eddy and Mason. Painting, etc., for six-story brick; owner, Fabrizio Nigro; architects, Mooser & Son; contractor, G. Orsi; signed, Oct. 30; filed, Nov. 17; cost $5250.

Fourth Ave. and Clement. Two-story frame; owner, Charles Hitchcock; contractor, J. Lund; signed, Nov. 15; filed, Dec. 1; cost $4950.

Franklin near Ellis. Two-story frame; owner, J. A. Bergerot; architect, J. Godart; contractor, Donald Currie; signed, Dec. 13; filed, Dec. 13; cost $7650.

Fremont street. Concrete work for brick building; owners, McIntosh & Wolpman; architect, E. Kollofrath; contractors, Camp & Carrillon; signed, Nov. 24; filed, Nov. 26; cost $1516. Carpenter work, etc; contractor, Charles Schutt; signed, Nov. 24; filed, Nov. 27; cost $2430. Brick work, etc; contractor, F. Wagner; signed, Nov. 26; filed, Nov. 27; cost $2940.

Harrison and 9th. Two-story frame; owner, Estate of James Phelan; architect, A. C. Lutgens; contractor, A. H. Wilhelm; signed, Nov. 18; filed, Nov. 19; cost $3490.

Hayes near Fillmore. Two-story frame; owner, Isaac Eliaser; contractor, E. C. Bletch; signed, Nov. 30; filed, Dec. 1; cost $2610.

Hoffman Ave. near Alvarado. Cottage; owner, J. S. Coats; builder, J. Heyman; cost $1750.

Hoffman Ave. near Alvarado. Cottage; owner, J. C. Coats; builder, J. Heyman; cost $1500.

Larkin and Post. Additions and alterations; owner, Fanny Morris; architect, A. J. Barnett; contractor, G. W. Duffie; signed, Nov. 22; filed, Nov. 23; cost not given.

Laguna and Olive Ave. Six flats; owner, L. Kutner; architect, W. J. Cuthbertson; contractor, Kinread Bros.; signed, Nov. 10; filed, Nov. 12; cost $9310. Plumbing work; contractor, Ickelheimer Bros.; signed, Nov. 12; filed, Nov. 12; cost $1447.

McAllister and Lyon. Three-story frame; owner, P. J. Rowan; architects, Shea & Shea; contractors, Demartini & Pagano; signed, Nov. 19; filed, Nov. 22; cost $4845.

Mission and Second. Steel work for six-story brick and granite building; owners, Wells, Fargo & Co.; architects, Percy & Hamilton; contractor, E. F. Jones; signed, Nov. 18; filed, Nov. 19; cost $9800.

Mission and Second. Brick and terra cotta work for six-story brick; owners, Wells, Fargo & Co.; architects, Percy & Hamilton; contractors, Richardson & Gale; signed, Dec. 8; filed, Dec. 9; cost $54,860.

O'Farrell near Webster. Two-story frame; owners, Mary E. & J. C. Konrad; architect, W. H. Armitage; contractor, R. J. Pavert; filed, Nov. 30; cost $2739.

Pacific Ave. near Van Ness. Three-story frame; owner, Frank H. Woods; contractors, Howkins & Lindsay; signed, Dec. 8; filed, Dec. 11; cost $8600.

Page near Masonic Ave. Two-story frame; owner, John H. Crow; contractor, Wm. Helbing; signed, Nov. 29; filed, Dec. 7; cost $5145.

Pulski near Jefferson. Cottage; owner, T. J. Sullivan; builder, J. Hegman; cost $1400.

Sixteenth and Hoffman. Carpentry mill work, etc., for two-story brick; owners, W. H. and Joseph Hyman; architects, Percy & Hamilton; contractors, Anderson & Greig; signed, Dec. 7; filed, Dec. 10; cost $10,875. Excavations, brick and terra cotta work; contractors, Peacock & Butcher; signed, Dec. 8; filed, Dec. 10; cost $3880. Plumbing, etc; contractor, H. Williamson; signed, Dec. 9; filed, Dec. 10; cost $1859.

Turk near Mason. Sidewalk illuminated tile work, etc; owner, G. G. Burnett; architect, J. E. Wolfe; contractor, H. Haustein; cost $640.25.

Twelfth Ave. No. 1726. Alterations, etc; owners, Mary and Annie Hagerty and Lizzie Coyle; contractor, Wm. Gilmour; signed, Nov. 23; filed, Nov. 30; cost $1115.

Van Ness and Olive Ave. Painting, etc; owner, J. Frowenfeld; architects, Salfield & Kohlberg; contractor, J. E. Ritzer; signed, Nov. 15; filed, Nov. 23; cost $1200.

Washington near Montgomery. Alterations and additions; owner, Achille Paladina; architects, Mooser & Son; contractor, L. Cereghino; signed, Dec. 10; filed, Dec. 11; cost $4500.

THE WEATHERWAX

PATENT SCREWLESS DOOR KNOB

SURPASSES ALL IN CHEAPNESS, DURABILITY AND APPEARANCE.
DOES AWAY WITH WASHERS AND SCREWS.
INSTANTLY ADJUSTS ITSELF TO ANY THICKNESS OF DOORS.
FITS ALL LOCKS.
SAVES TIME IN APPLYING, AND
CAN BE REMOVED INSTANTLY.

DIRECTIONS:

After Lock has been placed in position and escutcheon or roses have been screwed onto door, put the Knob Spindle through the Door, then put the Spring "B" in one of the Holes in Spindle; the free end of Spring should just clear the escutcheon or rose, when swung around, if too short move up one hole, if too long cut off with file or nippers, then put Knob on Spindle and press into place, when it will securely lock itself.

To remove Knob, insert a small awl into Hole "A" and press Spring down, at same time pull gentl yon Knob.

VOLUME XIX. JANUARY 20th, 1898. NUMBER 1.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

E PRINT in another column a paper that was read by Osborn Howes, Secretary Boston Building Fire Underwriters, before the Detroit Convention of Building Commissioners and Inspectors.

In his paper Mr. Howes points out very clearly that it is within the power of the Insurance Companies when these act collectively through a Board of Fire Underwriters, to enforce the building laws and the same course of proceedure on the part of the Insurance Companies would come very near enforcing a rigid observance of the Fire order. It would, in fact, prove a strong factor in doing away with the "pull supervisoral" which is now the great stumbling block of the Fire Warden who is inclined to enforce a strict observance of the Fire order on the property owners anxious to increase his rentals regardless of the rights of others. There would be but little incentive then to "revamp" old wooden rookeries because of the serious disadvantage he would be under when tempting to lease his property.

The remedy for this growing evil, as given in Mr. Howes' paper may have suggested itself to some of the local underwriters, if so it has been the proverbial light under the bushel, in so far as official publicity is concerned, but whether it has or not, the fact remains that the local board is not now acting collectively on these lines and it is to be assumed that internal dissensions have heretofore prevented concurrent action.

Yet the remedy is there, let the Underwriters make it generally known that the board would impose a penal charge of double rates upon buildings put up in palpable and serious defiance of the building laws or of the fire order, and we believe that after the risk assumed became generally known very few "improvers" or "revampers" would care to subject their property to it. Make the "revampers" see that ther was "nothing in in it" then with all hope of repeal gone the necessity for political pressure disappears and the 'revamper" becomes a law abiding citizen with a very wholesome respect for the regulations of the Fire Order as well as for the building laws of the City.

N THIS issue considerable space is given to an article on the wiring of buildings for electric lighting and it is our intention to print during the coming year a series of articles on this subject, an up-to-date knowledge of which, is daily becoming more and more important to every architect, and we do not doubt that many things now unknown to our ubiquitous man about town will see the light for the first time in some of these papers.

Architects realize that they must sooner or later, and the sooner the better, take up this subject seriously as a regular line of study and give to it a very considerable share of their attention, for this question of the efficient wiring of buildings can be no longer left entirely, as heretofore in many offices, to the contracting dealer in electrical supplies, who gives little or no attention himself to the mechanical execution of the work.

The Underwriters National Electric Association publish from time to time many useful suggestions for architects, also the results of recent tests, and these laboratory reports on all devices, after being carefully digested, and printed in these columns should prove very interesting reading to every reader of this Journal.

THE CHARTER makers are once more at their labors—and an appropriate time comes for suggestions. As most interesting to our readers we shall take under advisement for a short period the position of a Board of Public Works in a Charter for a City such as San Francisco. So far, a Board of Public Works has not appeared as an unmitigated success wherever it has had existence. When appointed by the Mayor as a few years ago was the case in our neighboring city of Oakland, it was so little a success that the citizens of that burgh abolished it in that form. Now it consists of the Mayor, City Surveyor and City Attorney, but it doesn't give satisfaction even in that form and the citizens are talking about getting up another new charter.

The Board of Public Works which carried out some quite large projects in London is now a think of the past and we hear of no desires on the part of the citizens to return to its government, but they seem content to have the Works Department carried on by a committee of the Council, the only complaint appearing to come from Contractors, who have been superseded by the system of day labor in vogue under the present regime.

So that looking at it from the standpoint of experience nothing much can be said in its favor. Looking at it from the standpoint of reason can more be said? Does any successful private corporation trust its engineering and architectural works to a Board of Engineers or Architects. No! they have their chief engineer or their architect and he is the man who is responsible for the work in his department—the man who receives the orders from the Board of Directors and carries them out without the aid of any middle Board.

Now why in the name of common sense cannot a corporation of the size of San Francisco—whose works and buildings do not compare with some of the private trusts and corporations do the same thing! Why is this bugbear, this Board of Public Works, allowed to rear its head in all our Charters. It cannot be for its use, for all the executive powers it has can be far more advantageously used by one man than by several, and its legislative powers can far more appropriately be done by a well chosen Committee of the City Council, who are elected by the people for the express purpose of Legislating.

Can it be for its beauty or example? Let the present like Boards now in existence tell us—the Police, Fire or Park Commissioners. Then what is it proposed for? Its only *raison d' etre*, until we receive further enlightenment, seems to be to find places for *political friends and to eat taxes*.

Although we have confined our remarks to a Board of Public Works as being more germane to the objects of our journal and as the Board dealing with the most important matters still the same strictures apply to all permanent Municipal Boards and Commissions.

Experienced men like the Chiefs of the Fire and Police Departments surely must be able to carry on the business of their departments better without the aid of amateurs than with.

The Departments of Education and Health again require no more Boards to carry on their business than the Record Department represented by the Recorder and County Clerk, or the Legal Department represented by the City Attorney and Sheriff—or the Judicial Department or the Financial Department with its heads the Treasurer, Tax Collector and Assessor. All these departments manage to wriggle along without Boards, why not the Works, Fire, Health, Police, Parks and Education.

As a mitigation of the absurdity of the position, it has been recently proposed to make some of the members of the Board of Public Works experts, engineers; but this is simply to make confusion more confounded. It is proverbial the disagreements of professionals—doctors disagree, Judges of the Supreme Courts are divided with diametrically opposed opinions. Architects are not always in accord, and Engineers are in the same boat; Actors render characters in quite different manners, etc., so that the result of having boards of Experts is simply to delay and emasculate the work in hand.

There is one more matter which the Charter Makers no doubt will incorporate into their document, i. e., the compulsory referring to the people before conclusion of all matters involving rights or large sums of money—e. g., such matters as franchises for garbage cremation, the acquisition or sale of public parks or real estate of any kind—or the erection of any building—outside of the ordinary business of the departments.

This is very necessary and good and would prevent temptation to deal in jobs.

AN ORDINANCE to establish the office of Electrical Inspector, printed in another column, is right in line with what should be done, a move in the right direction and there is no equitable reason why its passage should be delayed.

In this ordinance the Superintendent of the Fire Alarm and Police Telegraph of the City is made the Electrical Inspector and this one feature is, as a matter of fact, the only debatable question connected with it. The present superintendent, Mr. Hewitt, is unquestionably the right man in the right place and while it is true that to pass this ordinance means the making of the office purely a political one, this is an appointment that should be placed, simply as a matter of good business policy as far removed from all political combinations as it is possible to place it, in order that the Inspector may be at all times free to do his whole duty without fear or favor. But the Era of Bellamy is not yet and the difference between what we will get and what we want after Supervisonal action will be somewhat wider than Market street.

Looking at the question from all sides, and weighing well the probable effect and results to be obtained by what could be said or done, the political pressure is sure to outweigh all other interests and the chances for getting trustworthy, intelligent inspection would be fully fifty percent better if the appointment be placed in the office of the superintendent of the Fire Alarm and Police Telegraph, over what could be expected to come out of the usual run of "shad political" a spawn about as free to act independently or to conserve the interests of the community at large as the man in the moon would be.

WHO IS TO BLAME—AND HOW GREAT IS THE RISK?

S THE ELECTRICAL industry advances, with its progress arises also certain risks, that should be guarded against, and which cannot be overlooked, without damage to life and property, it is a well known fact that fires are becoming more numerous every day through Electric wiring. If we know the source, it behooves us to ascertain the causes, which are numerous, and when we speak of bad wiring it covers the field, and still leaves us as much in the dark as before, and what the readers of this paper should know is what composes bad wiring, and how to avoid it!

We will point out the principal causes, first willful neglect to comply with the underwriters rules in regard to insulators, and also the use of smaller size wire than that allowed for the same amount of current, poorly insulated wire and excessively heavy currents, inexperienced help, such as boys and men who know nothing of the business, and who are employed to save expense or add more profit—now who is at fault? This state of affairs exists! The blame may be placed in one quarter or another.

Take for example and for the purpose of illustration the case of a large new residence that is supplied with current from the Piedemont Street Railway system, being connected from the feeder at the corner of Santa Clara and Oakland avenues, Oakland, and carried down to the aforementioned residence about a block below. From all appearances the wire used to conduct the current from the feeder to the building is of the cheapest grade.

If the inside wiring is of the same class of workmanship as that of the outside, few if any of the rules and requirements of the National Electric Code—were observed—and the risk to property and even to life becomes five times greater than would be the case if taken from the regular incandescent circuit. Any person can see that a current having 600 volts electric motor force, would be six times greate for the same insulation than 100 volts E. M. F. would be, for of course, it can be readily understood that where a residence is supplied direct from a railway circuit of 600 volts as in the Oakland case specified above, the risk of fires, even with the best of devices and highest insulation of wires is a sufficiently hazardous one, but how much greater this risk becomes where cheap or unskilled labor is employed and low grade insulation. Take again as an illustration the handsome and very costly Chronicle Building and most of our readers will recollect that when the Electric Contractor lighted up the building for the purpose of testing the effectiveness of his work, it was discovered that the insulation used had become worthless by the absorption of moisture from contact with the concrete, into which they were embedded, and the wire used was totally incapable of carrying the amount of current supplied, which was easily apparent as the building was smoking from the lower to the upper stories.

Here, surely, is an example worth pondering over and these sort of things must have their effect on Architects, then why not take up this subjcet and give to it the attention that is most certainly its due. Fire Underwriters can be generally depended upon to look out for their own interests, although, in a fit of rigid economy the the board decided, some time ago to get along without an Electric Inspector, and in consequence the Electrical Contractors have had things pretty much their own way. But the mission of these papers is to stir up the Architects that they may become in their individual capacity, thoroughly versed in the skill of "how to wire" a building, in accordance with the rules and requirements of the "National Electric Code".

TEST OF METAL LATHING.

ON WEDNESDAY, January 26, an interesting test was made at Wells Fargo & Co.'s new building, designed to show the relative merits of different kinds of metal lath on wooden studs as a protection from fire—and incidently to test a variety of cements, concrete and metal partitions.

Under the direction of G. W. Percy, of Percy & Hamilton, Architects, a furnace had been built of brick, 4'0" wide, 8'0" long and 2'6" high above the grate bars with 1'0" space under the grate bars with air inlets all around.

In the sides of this furnace were inserted six panels 12"x20" of various types of metal partitions while the top of furnace was 3" thick of cinder concrete made in the proportions of one part Alsen's Portland cement, two parts sand and three parts of fine cinders, for one half of the top expanded metal was inbedded in the concrete, and the other half had ¼" twisted iron rods placed 3" apart. Over the centre of the furnace was a chimney 3'0"x3'0" and 8'00" high, built with 2"x4" O. P. studs with 2"x4" plate and sill, and width 2"x4" bridging all around near the centre of height. In the cenre of each of the four sides the studs were placed 16" on centres as is usual in frame buildings the corners were formed with two 2"x4" studs.

Each of the four sides were covered with a different kind of lath by the men representing them.

At the bottom the metal laths extended back, about 4"

on the under side of the concrete and nailed to it while at the top it covered the top of plate.

The plastering was applied by a disinterested plasterer in the usual manner of good three coat work of ordinary lime mortar. While some of the metal panels, were plastered outside and inside with lime mortars, some with Alsen cement plaster and some with Kings' Windsor cement.

It was intended to test four different kinds of metal lath in the chimney but the representative of one kind became dissatisfied and wished to prevent the test being made and strongly objected to its being considered a test of his lath, therefore, no further mention will be made of that one.

The three varieties that may be considered to be fairly tested were:—Roebling's Stiffened Wire, The Bostwick Steel Lath and the Expand Metal Lath.

The lower end of the chimney was further protected with Turnbull & Cullerton Steel Lathing nailed over the three coats of mortar and extending about 8" up on the studs and 6" under the concrete. This was plastered on two sides of the chimney with Royal cement plaster, on one side with Anti-Coloric boiler covering and on the other with Alpine cement plastering. The whole had been fairly well dried, when at 9:30 A. M., a small fire was started with dry kindling and a light fire was kept up until 10 o'clock when a hot fire was made with dry Manzinita cord wood fed in from both ends of the furnace. From this time on a hot roaring fire was maintained with the flames at times extending two or three feet above the top of the chimney.

At 10:30 A. M. the brick furnace was cracked on both sides near the centre also the concrete top on each side of the chimney and over the crack in brick work. The cement top which had been loaded with 275 lbs. to the square foot, now showed some deflection while hot steam was being driven from the green lumber forming the chimney.

At 10:45 A. M. the studs were scorched in places on each side and it appeared evident if the lumber was dry it would take fire.

The first fire on the frame occured at 10:47 and at the cross bridging on the Roebling side. Fresh mortar was applied on the outside to stop the fire and about five minutes later or at 10:52 fire started on the side lathed with the Bostwick Lath which was also extinguished with mortar at 10:58 fire started on the Expanded Metal side and was likewise extinguished.

In no case had the plastering fallen from the laths and the hot fire was maintained for 45 minutes longer, when the frame being practically burnt out, water was turned on from a garden hose, the fire extinguished and the chimney pulled down. The plastering freed itself completely from the laths in the fall.

The protecting coat of Royal cement at the bottom of the chimney was in a fair state of preservation.

The cement top which had deflected about ¼" with the heat and load, recovered itself to within 1-16" of a level line when the load was removed and the concrete cooled with water.

The concrete was practically uninjured by the heat and was broken with several blows from a sledge hammer.

All the panels on the sides of the furnace retained a large portion of the plastering on the inside while the outside showed no signs of injury.

This test was witnessed by several prominent Architects, a representative of the Underwriters and one of the Fire Wordens—and while it may not have satisfied any one as to the superiority of one kind of lathing over another it did show conclusively that any one of these metal laths if properly put on and properly plastered will withstand an intense heat for a long time.

FIRE-PROOF CONCRETE FLOOR CONSTRUCTION—THE TEST AT WELLS FARGO & CO.'S NEW BUILDING.

ELSEWHERE is printed the report of a test of metal lathing made at the Wells Fargo & Co.'s new building, under the direction of Mr. G. W. Percy of Percy & Hamilton the Architects of the building. That report covers the part taken in the test by the different kinds of metal lath represented, while it is the purpose of this report to deal with the part taken in the test by the two systems of concrete fireproof floor construction, as witnessed by the representative of this Journal on the ground.

The top of the furnace was three inches thick, made in the proportions of one part Alsens Portland Cement, two of sand and three fine cinders—for one-half of the top 2½ guage expanded metal was embedded in the concrete and for the other half twisted steel rods placed three inches apart were embedded in concrete. The theory on which both of these constructions are based being that concrete having a great compressive strength but very small tensile strength, it should be used exclusively in compression. To obtain the requisite tensile strength, square steel rods, twisted cold—Ransome System—are embedded in the concrete, while the other system in the test get their tensile strength by embedding in the concrete expanded metal—a home production.

Advocates of the steel rod system make two broad claims—1st—That these rods are firmly held in place by the concrete, and that the square surface twisted, forms a hollow which ties the concrete in the direction perpendicular to the rods, and the twist ties in the direction of the rod. 2d—That experiment has taught that narrow ribs of concrete are ample to resist all the strain in the vicinity of the twisted rods.

The advocates of the expanded metal system claim, 1st—that expanded metal embedded in concrete forms a monolithic mass 2d—that with much less weight of metal the construction is positive in strength 3d—that great tensile strength is acquired by placing the expanded metal on the under side of the slab, slightly embedded in the concrete.

After the chimney had burned out and had been torn down, the fire was put out, and top of the furnace was deluged with water then began the destruction of the top of the furnace, a heavy sledge being used for the purpose.

The slab containing the twisted steel rods was broken through as soon as the sledge struck the space between the rods. On the other slab it required many severe blows with the sledge to destroy the monolithic mass that had been formed by the expanded metal system—fully sustaining the claim of great tensile strength, for the advocates of the expanded metal fire-proof concrete floor construction.

THE ENFORCEMENT OF BUILDING LAWS.*

THE MANNER in which building laws can best be enforced is a problem which all municipalities must face which have regulations of this kind. Public interest requires that where a well-considered and tolerably rigid building law has been enacted, its requirements should be strictly complied with, but as such a course ordinarily involves a larger expense to individual citizens than would be incurred by ignoring or evading the building law, it is not at all strange that public spirit proves altogether inadequate to the work of enforcement, and that penalties are needed to compel the self seeking citizen to do what he should do out of regard for his fellow man.

It is always doubtful whether a building law in its requirements should go far in advance of the general sentiments of the people. If public opinion does not in the sustain it, not only will there be numerous infractions, but it will be found difficult to adequately punish those who committed these. For this reason one of the best methods, not only of enforcing a building law but of procuring good building laws, is the endeavor to properly educate the people on all matters relating to good construction.

Another potent factor—a factor which might be made, under proper regulation, even more potent than it is in the enforcement of the law—is the power of the insurance companies, when these act collectively through a board of fire underwriters. It is for the seifish interest of the fire insurance companies that the buildings in a city should be put up in a safe, fire-resisting manner. The fire insurance companies realize that they are likely to gain more by reducing fire losses where there is good construction than the community is likely to gain through the reduction in rates. Both changes will come about, but the profit to the underwriters is the first of these two results secured, and it is ordinarily the larger of the two. For this reason intelligent fire underwriters in all of our American cities can be counted upon to aid the public authorities in the enforcement of such building laws as are believed to be salutary and satisfactory from a fire point of view. Naturally the fire insurance men have very little to say about plumbing and ventilation, and hence are no more likely to interest themselves in these matters than the marine insurance companies would be likely to interest themselves in the matter of the thickness of the walls or the height of the builnings in a city.

While it may not be at all times easy to bring about concurrent action, I am strongly of the opinion that if the building inspectors of any of our large American cities made an appeal to the local board of underwriters the latter would agree to adopt and enforce a system of penal charges in those cases where there was defective construction, a method which would go a long way toward restraining builders and owners of buildings from indulging in these evasions. In these modern days practically all buildings and their contents are insured, and in all business buildings the question of the rate of insurance becomes a matter of no small importance in the competition in trade which is all the time taking place. Thus, for example, the owner of a building the contents of which, in consequence of defective construction, rates twice or three times as high as the rate on the contents of another building, is placed at a serious disadvantage in attempting to lease his property. Hardly a day passes that I am not appealed to by some would-be tenant to find out what his rate will be if he takes the lease of a certain building. The owners of these buildings also realize the merit it is to them of having structures which rate low, and ordinarily are willing to go to quite a little expense for the purpose of attaining this desired end.

Now if it were generally known that the board of underwriters of a city would impose a penal charge of double rates upon buildings put up in palpable and serious defiance of the building law, I am inclined to believe that after the risk assumed became generally known very few builders would care to subject their property to it. A penalty of this kind would in most instances be levied without hope of repeal, because the political pressure which might be brought in play at a city hall would have little or no effect in influencing the action of the members of a board of underwriters. The latter would realize that the defect in question was one which had been indulged in at their expense, and that the only way to prevent the constant repetition of a similar fault was to impose a penalty upon the fault-doer which he or she would not forget. I believe, as I said above, that if the building inspectors asked in this way the co-oporation of the fire underwriters, they would receive the needed aid. The details of this co-operation would consist in an agreement that where buildings were reported by the inspector to be put up in defiance of what he believed to be the building law, the underwriters would agree on their part to materially increase their rates of premium upon the building thus reported and its contents. It would not be impossible to go beyond this and have an arrangement made by which the companies, in the main, would agree not to insure the building at all; but possibly this might be a system of penalization which would be so severe as in the end to defeat itself. It would, however, be possible to make the advance in rates I have referred to, and in order to emphasize the fact in the printed list of rates it would also be possible to have it noted that the rate was increased because the building in question was put up in defiance of the building laws which the State had adopted for the protection of its people.

* Read by Osborne Howes, Secretary Boston Building Fire Underwriters, before the Detroit Convention of Building Commissioners and Inspectors.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

THE CATHOLIC Church of St. Paul, which is now being built at the corner of Hayne Avenue and 22d Place, Chicago, will when completed, be one of the most remarkable edifices in the country, and Chicago will take the first step in a style that is altogether opposed to the one she invented, the steel skeliton building filled in with terra cotta. The church of St. Paul will be entirely of brick masonry, even the window frames in which the glass is set will be of brick. From floor to roof, outside and inside, walls and ceilings, casements and stairways, the seen and the unseen, will be honest vitrified clay, depending upon itself alone for its support and its decoration.

The style of architecture adopted is late Romanesque and Gothic of the 12th to the 13th Centuries. The total length of the church, including the sacristy, will be 209 feet. The width over all will be 108 feet, and the two towers each 32 feet square at the bottom, will be 245 feet in height above the sidewalk. The body of the church will be 68 feet wide.

Our illustrations are from drawings and a model.

The architect Henry J. Schlacks of Chicago is a young

man of thirty years of age, who has made church building a specialty ha ving traveled extensively in the old world. No doubt the b uilding of St. Paul's church will put him in the front rank.

There will be no plaster in this church, no stucco, no imitation marble, nor shams of any kind, for the Rev. Geo. D. Heldman, who is in charge, considers that a building consecrated to the teaching of the eternal truth should itself be true and, as a good brick is one of the most durable things in nature or art, he will let it bear witness to its own strength and beauty.

The main entrance to the church will be through six pairs of doors into three large vaulted vestibules, leading directly into the nave and side aisles. The nave will be entirely free from columns, as there will be no pews in the side aisles, these being used as aisles only, extending all around the church and back of the high altar.

The height of the nave will be seventy-five feet, its width will be forty feet between the columns which divide it from the side aisles. The body of the church expands as we approach the front and has the bulk of the seating capacity in the transept, so that the majority of the congregation is brought within close proximity to the sanctuary.

This style of building is not anything new in Europe, for there are very old churches there and even Cathedrals, entirely of brick, with vaulted brick roofs, brick groins and ribs, and all the decorative effects are obtained with burned clay in the form of brick or terra cotta. Some of these buildings are very beautiful, and all are in admirable preservation, but as we before stated, nothing of the kind has ever been done in the United States, and the architectural and building world will watch the work with greatest interest, but in consequence of its being so novel here, no bricks that were suitable could be found in the market. Accordingly the builder has had to order the various shapes required. There will be no less than 208 different kinds of these Gothic bricks and mouldings, and they will be specially made by the Webster Fire Brick Company of South Webster, Ohio. The roofing tile, at the moment of writing, has not been selected, though it will be probably before this leaves the press. The terra cotta is being specially made by the North Western Terra Cotta Co., Chicago. This material will be extensively used, both inside and out, from the finials on the spires downward. White terra cotta figures of religious subjects, instead of the usual sculptures, will decorate the interior. The altars, communion rail, front of organ loft and pulpit will all be of terra cotta.

About 2,500,000brick will be used, of which 500,000 are fancy bricks, mouldings, etc.

Window washes and water drips will be of bricks and mouldings of special design. It is stipulated that all face bricks and mouldings shall be vitrified, so that they will be non-absorbent and consequently self-cleaning. Any kind of brick that is absorbent was objected to because experience teaches us that the soot and smoke of a great coal consuming city, is not only irremovably fixed on the face of an absorbent brick, but carried into its pores. A glazed or enameled brick was distrusted because of the uncertainty of the connection between the surface and the body, with consequent risk of crazing and scaling. A vitrified brick or tile is justly felt to be absolutely reliable.

The prevailing color of the brick work will be a light buff, with warmer colors for trims running into dark brown. The body of the walls will be light buff and yellow. The color scheme will be the same in the interior but the exterior will be somewhat lighter. The whole ceiling will be of brick and tile vaulting. This vaulting tile will be of different sizes as required, such as 4"x12", 6"x12", etc., and 1" thick. The ribs of the arches and groins will be of moulded bricks, the keystones of terra cotta. In short, the whole construction will be purely ornamental brick masonry.

The brick casements will have grooves into which the glass will be set and fixed with putty. The grooves are deep, so that the piece of glass being slipped in on one side goes in far enough to enter the opposite groove, thus the glass is held securely, back and front, by the brick, the putty prevents any side movements.

This brick construction would not have been possible in some parts of the City of Chicago. It can be carried on this spot because the foundations go down to the solid rock, which lies at a depth of less than 20 feet from the sidewalk.

AN ELECTRICAL INSPECTOR WANTED.

TO establish the office of electrical inspector for the City and County of San Francisco, and to regulate and define the duties of such office, and to establish rules and regulations concerning electrical appliances.

AN ORDINANCE:

The Board of Supervisors of the City and County of San Francisco, Do Hereby Ordain as Follows:

SECTION 1—The Superintendent of the Fire Alarm and Police Telegraph of the City and County of San Francisco, is hereby made the electrical inspector in and for said City and County.

SEC. 2.—The electrical inspector for the City and County of San Francisco, is hereby authorized, empowered and directed to regulate and determine the placing of electric light, heat or power wires in and on buildings in said City and County so as to prevent fires, accidents or injury to persons and property, and to cause all electrical appliances to be so placed, constructed and guarded, as not to cause fires or accidents or endanger life or property; and whenever in the judgment of said electrical inspector any electrical appliance shall be defective by reason of improper or insufficient insulation or for any other cause, the said electrical inspector shall at once cause the immediate removal of such defect.

SEC. 3.—The said electrical inspector, or other competent persons delegated by him, shall have the right at any time to enter any building, manhole or subway, in the discharge of his official duties, or for the purpose of making any tests of electrical apparatus or appliances therein contained. And for that purpose he shall be given prompt access to all buildings, public and private, and to all manholes and subways, on application to the company or individual owning or in charge or control of the same.

SEC. 4.—The said electrical inspector or competent person delegated by him shall have the power to cause the removal of all wires or the turning off of all currents, where the currents interfere with the work of the Fire Department.

SEC. 5.—No alteration or change shall be made in the wiring of any building, nor shall any building be wired for the placing of electric lights, motors or heating devices, without first securing from the said electrical inspector or competent person delegated by him, a permit therefor, nor shall

any change be made in any electric plant after inspection without notifying the said electrical inspector or person delegated by him and securing a permit therefor.

Upon the completion of the wiring of any building it shall be the duty of the company, firm or individual doing the same, to notify the said electrical inspector or competent person delegated by him, who shall at once inspect the same, and if approved by him, shall issue a certificate of satisfactory inspection which shall contain the date of such inspection and an outline of the result of such examination; but no such certificate shall be issued unless the electric light, power or heating installation and all apparatus, wires, etc., connected with it, shall be in strict conformity with the rules and regulations hereinafter set forth; nor shall current be turned on such installation until said certificate be issued.

SEC. 6.—Said electrical inspector shall keep a record of all permits given and inspections made.

SEC. 7.—Any person, firm or company who shall violate any of the provisions of this ordinance, or fail, neglect or refuse to comply with the rules and provisions of this ordinance, or who shall fail, neglect or refuse to comply with any order or request of said electrical inspector or competent person delegated by him in pursuance of and by the authority of any of the provisions of this ordinance or rules therein contained, shall be deemed guilty of a misdemeanor, and upon conviction thereby, shall be fined not more than one hundred (100) dollars or to be imprisoned not more than (90) days.

SEC. 8.—All electrical construction, all material and appliances used in connection with electrical work, and the operation of all electrical apparatus, shall be in conformity with the rules and regulations set in what is known as the "National Code of Rules for wiring Buildings for Electric Light, Heat or Power", as the same are now established, and the said rules and regulations, together with any amendments and changes made therein from time to time, are hereby adopted and approved.

SEC. 9.—This ordinance shall take effect and be in force from and after its passage.

CONVENTION OF SANITARY SCIENTISTS.

TO BE HELD IN NEW YORK EARLY NEXT SPRING.

AN INTERNATIONAL Health Exposition will be held at the Grand Central Palace, New York City, for five weeks, beginning April 25th next, under auspices and with a breadth of scope which are a guarantee of conscientious and intelligent effort, and which cannot fail to awaken a wide-spread popular interest.

A number of food shows have taken place in this and other cities, besides collections of building materials, notably in New York, Brooklyn and Chicago, while there is a permanent Hygienic Museum in Washington. But no attempt has heretofore been made to gather together under one roof the wonderful variety of objects which illustrate the immensely wide and important field of sanitary science and the marvelous progress which has been made in that direction of recent years.

The time is ripe for such an undertaking. An extraordinary revival of interest in sanitary matters has lately been shown, partly because of recent epidemics at New Orleans, and at other places, and also as a result of the late municipal reform movements, which have led to an active discussion of street cleaning methods, public baths and play grounds, water supply and other sanitary problems.

There will be a display covering more than three acres of floor space, of practical apparatus and appliances of all kinds, taking in everything from Mr. Atkinson's Aladdin Stove to a huge garbage crematory in actual operation.

There will be all the modern systems of house-heating, ventilation, plumbing, etc., comparative exhibits of new and primitive hospital arrangements, systems of sewerage for cities and villages, a model school room and the other kind, model tenement houses, health food, etc.

The exhibits, however, are not all there is of the exposition. There will be provided by the management a course of popular lectures for every day, discussions by various societies, representatives of Boards of Health, etc., and the whole affair in its full development will be in reality an Educational Congress.

No exhibits will be accepted which have not been approved of by specialists in their respective departments.

Offices of the Exposition are now open at the Grand Central Palace.

One of the most interesting features will be the Department of Electricity, showing its applications not only to health and sanitary matters, but, as an aid in household economics.

Mr. Luther Stiringer, Consulting Electrical Engineer of The World's Fair, Atlanta, Nashville and Omaha Expositions, has been retained in a similar capacity for the International Health Exposition.

This is the first public exhibit which Tesla has ever made in New York, and his accomplishments are always of world-wide interest.

Mr. Charles F. Wingate, the Sanitary Engineer is the Supervising Director, and in conversation with a representative says of his part in the exposition:

"The present Exposition is a product of evolution, and a striking instance of taking the tide at the flood. My own connection with it, which came about quite accidentally, is a case of greatness being thrust upon a person.

"The interest in sanitary subjects is confined to no one class of persons. Dr. Stanley Hall, the famous educator, devoted fully half of his recent address on laying the corner stone of a Womans' College, to the subject of health. Special hygienic departments are being added in many periodicals, and health articles fill much of the womans' page in the daily papers. Boards of Trade and Chambers of Commerce are alike concerned in discussing measures for the protection of the public health.

"A splendid opportunity is therefore presented through the International Health Exposition to educate the public along these various lines, and there can be no question as to its permanent usefulness.

"Probably the most attractive feature in the Exhibition will be the arrangement of what may be called Sanitary Living Pictures, to show certain features in a practical way. For example, a tenement house sweat shop will be shown in actual operation, in contrast to a model work shop with all modern improvements; also a police lodging room redolent with damp, and every kind of foulness, side by side with a model lodging house, such as may be seen opposite Bellevue Hospital; also an old County Poor House cell, with a "mad

woman" chained to the floor, in contrast to a modern insane asylum ward; a model school in contrast to an unmodel school, and so on with every department of practical hygienic.

"An exhibition of this kind appeals chiefly to women, who have the interest of the home so largely at heart. When we consider the services which women have performed in the line of sanitation, it might be call distinctly "Woman's Field."

The list of the Advisory Board already appointed, comprises more than ninety specialists in the various lines of anitary work, among whom may be mentioned:

Dr. Stephen Smith, President Department Public Charities, New York.

Hon. Andrew H. Green.

Albert Shaw, Editor Review of Reviews.

Edward Atkinson.

Alfred T. White, Ex-Commissioner of Public Works, City of Brooklyn.

Samuel Gompers, President American Federation of Labor.

Miss Frances E. Willard, President W. C. T. U.

Dr. H. W. Wiley and B. G. Fernow of the U. S. Dept. of Agriculture.

Mrs. Melville Dewey.

Col. Wm. G. Church, Editor of the Army and Navy Journal.

Dr. H. P. Baker, Secretary Michigan State Board of Health.

Dr. Mary Putnam Jacobi.

Dr. George F. Shrady, Editor Medical Record.

BOOKS AND PERIODICALS.

THE AGE OF STEEL, 40th Anniversary number, St. Louis, Mo., January, 1898. The publishers of the "Age of Steel" celebrated its 40th Anniversary by the issue of a handsomely printed number of over one hundred page giving not only a brief history of the publication from the start in 1857, but also an account of the commercial growth of St. Louis in the forty years. Fully illustrated with portraits of men who have been prominent in forwarding its growth.

LIPPINCOTT'S Magazine for January contains for its complete novel John Olmsteads' Nephew by Henry Willard French—a very interesting but improbable story. The article "Irrigation From under Ground" by John E. Bennett has a peculiar interest for the people of this Coast—while an account of "Druggists Ancient and Modern" by Oscar Harzberg will prove interesting reading to all those who have to avail themselves of the druggists' art to regain their health and happiness.

THE NEW TIME for December, 1897, a Magazine of Social Progress. Published by Charles H. Kerr & Co., 56 Fifth Ave., Chicago, Ill. Price ten cents.

The circulation of "The New Time Magazine" is claimed already as forty thousand copies and the publishers hope to double it three times more before June, 1898. This claim does not appear unreasonable considering the extremely low rate the publishers have placed upon the journal that contains much of interest to the general public, and appeals strongly to that class that is constantly increasing who have an interest in the welfare of Social Progress.

SEMI-ANNUAL SUMMARY OF BUILDING OPERATIONS.

IN the following tables we present the number and value of buildings erected in San Francisco during the first year.

FOR FIRST SIX MONTHS.—1897.

1897	No. of Buildings	No. of Contracts	Brick Building Value.	No. of Buildings	No. of Contracts	Frame Building Value.	No. of Buildings	No. of Contract	Alterations & Addit'ns Value.	No. of Buildings	No. of Contracts	Total Value.
Jan'ry	12	16	$ 128,610	22	26	$ 53,524	3	3	$ 7,917	37	45	$ 190,081
Feb'ry	6	17	181,128	21	24	71,475	8	8	28,028	35	49	280,631
March	10	18	293,132	44	47	135,610	10	10	17,234	64	75	465,975
April	6	28	194,762	71	75	217,570	25	25	100,780	102	125	472,912
May	13	19	116,959	40	43	147,385	11	11	13,086	64	73	277,427
June	7	9	48,718	45	48	162,750	19	20	49,994	71	77	261,462
Total	54	101	$ 888,329	243	263	$ 788,123	76	77	$217,039	373	441	$1,888,488

FOR SECOND SIX MONTHS.—1897.

PROGRAMMES FOR TH INTERNATIONAL COMPETITION FOR THE UNIVERSITY BUILDINGS.

ARCHITECTS desirous of entering the Competition for the Phebe Hearst Architectural Plans for the University of California, can obtain Programmes and Maps, by applying to the Chapter of Architects, room No. 17, 408 California Street, or at this office.

BUSINESS MOSAICS.

The results of the past years hardwood lumber business have been so flattering with Mr. Fred. L. Pfingst that he has decided to enlarge his field of operations by adding more lines of building materials and more accounts. Mr. Pfingst is now visiting the larger manufacturing centres of the Eastern States for the purpose of securing good lines and expects to be back about the first of March fully equipped to battle for his share of this years' business.

As will be seen by the new advertisement of Charles J. Waterhouse on page x of this journal he has removed his office to 421 Market street. Mr Waterhouse is the agent for the sale of Mr. Samuel Cabot's various articles so usefnl to builders of the present day, as Cabot's Creosote Stain, Sheathing and Deafening Quilt, Mortar Stain, Pulps and Brick Preservative. Also agent for the various brands of Roofing Tin as manufactured by the well known firm of N. & G. Taylor Co. of Philadelphia.

The J. L. Mott Iron Work—New York, Boston, Chicago, St. Louis and San Francisco—Established 1828. The Pacific Coast Representative of the above company has, at 27 Flood Building, a splendid show of goods in their line. Any thing in the way of Sanitary Specialties can be seen, from bath room to the kitchen can be furnished with these goods that are always sure to give satisfaction to the purchaser. Parties are especially invited to call at their show rooms as above. Mr. M. S. James will take pleasure in showing these goods and explaining the advantage of their use.

Attention is called to the advertisement of Mr. G. C. Dallamore, 414 Devisadero street, San Francisco, page vii of this Journrl. The Titus Improved Patent Sewer Gas Trap Tide and Flushing Gate has the recommendation of members the Board of Health as well as testimonals from practical men who have the Trap in use. First Premium from Mechanics Institute for a number of years.

Mr. Dallamore, a practical plumber and gas and steam fitter, has had years of experience in his line of business nd can be relied upon as doing well all work undertaken y him.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street,

Seth Babson, Pres. H. A. Schultz, Vice-Pres.
Oliver Everett, Sec. John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Theo. A. Eisen, Pres. Arthur B. Benton, Vice-Pres.
William C. Aiken, Sec't. August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

Jos. C. Hornblower, Pres. Jas. G. Hill, Vice-Pres.
E. W. Dunn, Jr., Sec. W. J. Marsh, Treas.

Association of Architects of Arizona, meetings held at Phoenix, Arizona.

D. W. Millard, Pres. T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

E. J. Molera, Pres. W. F. C. Hasson, Vice-Pres.
Otto Von Gelders, Sec. Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

S. H. Kent, Pres. Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. M. V. Brady, Sec.

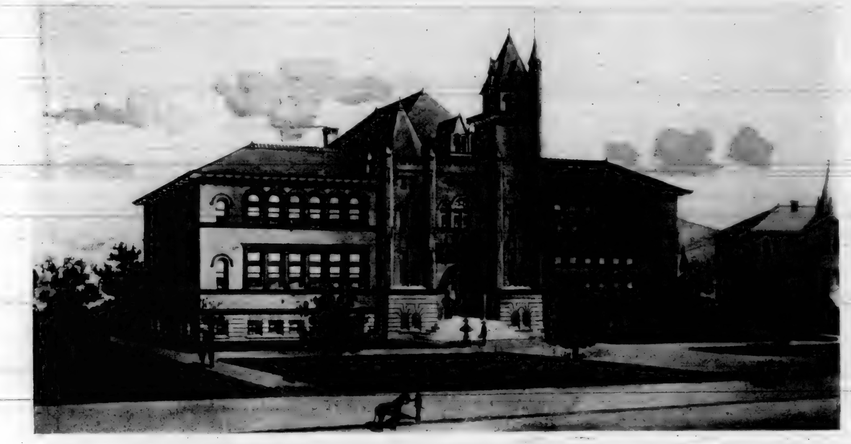
THE VACAVILLE UNION HIGH SCHOOL.

THE cut here represented of the new Union High School Building now being erected in the town of Vacaville, for the Vacaville Union High School District, from the drawings of Cunningham Bros., Architects of Oakland, which were accepted some months past. As the above firm are specialists in school house architecture, the District is assured of a modern building, with rooms properly proportioned, amply lighted, and well ventilated.

The plans contemplate a two-story frame structure of Venetian-Renaissance design. The building will have a frontage of 120 feet, with a maxium depth of sixty-seven feet. There will also be a basement under the entire building, containing lavatories, heating and ventilating plant, recreation rooms, etc.

The main entrance leads to a large entrance hall, on one side of which opens the principal's office, and on the opposite side, the library. The main corridor, will be ten feet wide in the clear, with three class rooms opening off it on the first floor, two class rooms, chemical and physical laboratories, and a large assembly hall, on the second floor. Teachers' lunch and dressing rooms, lavatories, hat and coat rooms, etc., are also provided. The unilateral system of lighting, is used in class rooms throughout. Special attention has been paid to the heating and ventilating. California yellow pine, will be used throughout for the nterior finish.

The building is now enclosed and it will require about fifty days for its final completion.



THE VACAVILLE UNION HIGH SCHOOL. CUNNINGHAM BROS., ARCHITECTS, OAKLAND, CAL.

HEATING, VENTILATING AND CLOSETS.

The Board determined from the start to incorporate the most modern and practical Heating, Ventilating and Sanitary work and appointed a committee of three to personally inspect the workings of the various systems offered.

As a result of this inspection the W. Morgan & Co's. Heating and Ventilating System and also their Ventilated Flushing Water Closet System was adopted complete.

The system is applied in a very systematic manner, occupying but a small portion of the basement, leaving ample play rooms.

A double air warmer or furnace is located at the base of the flues supplying fresh air to the rooms above, these flues drawing their air supply from a brick warm or cold air chamber, which in turn draws its supply from fresh air rooms and windows located on each side of the basement. A powerful ventilating shaft 4x5 feet and 60 feet high draws the foul air out of each room by means of vent flues leading from each room to the base of this main shaft, the amount of exhaust is regulated by a small stack heater placed in the shaft.

By this arrangement each class room has its own independent fresh air supply and foul air exhaust flue, the teacher or occupant of the room having control of the temperature by means of a "heat regulator" which admits either warm or cold air through the same flue.

The practical workings of this system can better be determined by the ten guarantees of the company two of the most important reading as follows

"That each room shall have a continuous fresh air supply—warm or cold—so that if any room should become overheated the temperature can be reduced at the rate of three degrees for ever ten minutes, without opening doors or windows."

"That said apparatus shall secure good ventilation in all rooms, the capacity of the plant being sufficient to supply enough fresh air to each room to renew the entire volumn of air in said rooms from four to six times per hour, without harmful draughts as from open doors or windows."

One of the most important features of this system (different from anything else offered) is the peculiarly constructed furnace, which makes it impossible to "over-heat" the air, the large flange radiating surface insuring an increased volumn of air at a decreased temperature.

In the rear basement rooms are found the boys' and girls' closets.

This closet system is most perfect in operation, and a combination of air and water is used, the latter to wash or flush the troughs and the former to draw all foul oders or gases through the closet vault, and expel same into the open air at the top of the building, keeping these lavatories clean and healthy at all times.

From the practical workings of this entire system in the various school buildings inspected by the committee and from the brief description as herein given it will be apparent that The Vacaville Union High School Building will be one of he fo remost it its Modern Sanitary Appliances.

THE WORLD'S ARTISTS INVITED TO COMPETE.

PLANS FOR A UNIVERSITY—MUST BE IMPOSING, SERIOUS AND NOBLE—THE TRUSTEES OF MRS. HEARST'S MUNIFICENCE MAKE PUBLIC THE CONDITIONS.

THE TRUSTEES of the Phebe A. Hearst architectural plan of the University of California have issued their invitation to the architects of the world to co-operate "in the preparation of a permanent, general plan of the buildings and grounds which are to compose the University of California."

The invitation is in the form of a handsomely printed pamphlet of forty pages, entitled "Programme for an International Competition for the Phebe Hearst Architectural Plan of the University of California." It opens as follows:

The trustees appointed by Mrs. Phebe A. Hearst hereby invite the co-operation of the architects of the world in the preparation of a permanent, general plan of the buildings and grounds which are to compose the University of California, in Berkeley, near San Francisco, Cal.

J. B. Reinstein, James H. Budd, William Carey Jones. Trustees of the Phebe Hearst Architectural Plan of the University of California. Dated at San Francisco, Cal., December 3, 1897.

The competition is to be double, a preliminary and final. The preliminary is open to the world. The final will be limited to those whose work in the preliminary is decided by the jury of award to be of such worth and merit as to entitle them to be considered in the final competition. All plans submitted for the preliminary competition must be deposited with the United States Consul at Antwerp, Belgium, before July 1, 1898.

Rules have been adopted so that the members of the jury of award will not know who is the author of any plan. All plans that the jury do not consider worthy of being retained will be returned to their authors. The plans retained will become the property of the University of California, but the name of a successful author will not be made public without his consent. At least ten plans will be retained, and if only that number the author of each will receive $1500. If not exceeding fifteen plans are retained $1200 will be paid to each, and if more than fifteen are retained $1000 will be paid to each.

Competitors in the final competition who desire to study the site of the proposed buildings on the ground will be provided with transportation and expenses for the journey from their residences to San Francisco and return. A total sum of at least $20,000 will be devoted to premiums for the best plans in the final competition, and of this at least $8000 will be awarded to the plan classed as No. 1. The ultimate execution of the plan is entirely in the hands of the University, and competitors are informed that a contract with any of those receiving an award "will be a desirable consequence of the competition, but in no wise a condition thereof." The preliminary plans retained will be publicly exhibited at the Mark Hopkins Institute of Art.

The jury for the preliminary competition will be international, being composed of these members: Messrs. R. Norman Shaw, 6 Ellerdale Road, Hampstead, London; J. L. Pascal, 8 Boulevard St. Denis, Paris; Paul Wallot, 6 Hahnel-Strasse, Dresden; Walter Cook, 674 Broadway, New York, N. Y.; J. B. Reinstein, 217 Sansome street, San Francisco, Cal. For the final competition four architects will be added to this jury, who will be chosen by its members, aided by lists of names submitted by successful preliminary competitors. Competitors successful in the preliminary competition will have not less than six months after the decision in the preliminary competition within which to send in their plans for the final competition.

Eight thousand copies of this programme have been issued, four thousand copies in the English language, two thousand in the French and two thousand in the German. The programmes, documents, pictorial aids and the material necessary for the competitors have been distributed to the Ministers of Foreign Affairs of the Argentine Republic, Brazil, Chile, China, Japan, the Minister of Public Instruction and Fine Arts in Turkey, the technical societies, respectively, of Spain, Sweden and Roumania, and the leading organizations of architects in Austro-Hungary, Belgium, Canada, Denmark, Germany, Great Britain and Colonies, Holland, Italy, Mexico, Portugal, Russia and Switzerland. In the United States they have been sent to the Secretary of State of every State, to chapters of the American Institute of Architects in Boston, Brooklyn, Buffalo, Chicago, Cincinnati, Cleveland, Denver, Detroit, Indianapolis, Kansas City, Los Angeles, Lynchburg, Va.; New York, Philadelphia, Pittsburg, Providence, Rochester, San Francisco, Seattle, St. Louis, Washington, and to the Mayors of the other principal cities.

It is stated that the various buildings now standing on the grounds need not be taken into consideration; nor need present paths or roads be considered. The general grouping of requirements includes a library with a capacity for 750,000 volumes, a gymnasium with separate halls and appurtenant accommodation for men and women students, and separate swimming baths for each, two auditoriums, of which one shall seat 5000 people, dormitories, club-houses for students and faculty, an elaborate military establishment, an infirmary, and all suitable structures and provisions for the fifteen departments thus far contemplated by the University.

While there are no limitations on the materials to be used, it is stated that California abounds in beautiful and durable building stones. The programme closes with a scientific abstract of climatic conditions at the University of California for the past ten years. Requests for further information may be addressed to Trustees Phebe Hearst Architectural Plan, University of California, 217 Sansome street, San Franrisco, Cal.

CITY BUILDING NEWS.

Bush near Powell. Three-story frame; owner, John G. Fezhl; contractor, Casper Zwierlein; signed, Jan. 4; filed, Jan. 8; cost $5775.

California and Montgomery. Alterations and additions; owner, Thomas J. Clunie; architects, Curlett & McCaw; contractor, Wm. Linden; signed, Dec. 13; filed, Dec. 14; cost $16,890.

Clara street, No. 141. Additions and alterations; owner, E. S. Guglielmetti; architects, Oakey & Jordan; contractor, C. A. Holm; signed, Nov. 10; filed, Dec. 27; cost $1000.

Clayton near Fell. Two-story frame; owner, James T. Gaynor; architects, Shea & Shea; contractor, B. Dryer; signed, Dec. 30; filed, Jan. 3;

Dolores near 17th. Mill work, etc., for four-story and additions; owner, College of Notre Dame; architect, C. J. I. Devlin; contractor, J. W. Smith; signed, Dec. 17; filed, Dec. 17; cost $23,988. Concrete, etc.; contractors, Stauck & Grussel; signed, Dec. 17; filed, Dec. 17; cost $2870. Excavations, brick work etc.; contractors, Peacock & Butcher; signed Dec. 17; filed, Dec. 27; cost $3284. Plumbing; contractor, W. F. Wilson; signed, Dec. 17; filed, Dec. 17; cost $1817. Lathing and plastering; contractor, Martin Carrick; cost $2880. Hot Water Heating; contractors, Holbrook, Merrill & Stetson; cost $3507. Painting, etc; contractors, Joe; Cahill & Co.; cost $1745.

Eddy near Powell. Brick addition to front of Tivoli Theatre; cost $1500.

Eleventh Ave. near Pt. Lobos. Cottage; owner, Mrs. Carrie C. Ayres; contractor, Z. O. Field; signed, Dec. 20; filed, Dec. 23; cost $1087.

Ellis and Pierce. Two-story frame; owner, Margaret O'Brien; contractor, H. E. Kronnick; signed, Dec. 22; filed, Dec. 22; cost $4500.

Fulton and Webster. Alterations and additions; owner, Henry Schmidt; architect, O. Everett; contractor, Jeremiah T. O'Brien; signed, Jan. 5; filed, Jan 5; cost $2814.

Geary near Mason. Additions and alterations; owner, Charles Schroth; architect, A. W. Marquis; contractor, John Wirey; signed, Dec. 20; filed, Dec. 22; cost $2307.

Jackson near Larkin. Alterations and additions; owner, Mrs. Margaret Hyland; architects, Mahoney & Ryland; contractor, S. Saywell; signed, Nov. 22; filed, Dec. 16; cost $2250.

Jackson street, No. 734. Steel work for a tank frame; owner, M. Schuppert; architect, A. C. Lutgens; contractor, H. Ralston; signed, Dec. 27; filed, Dec. 27; filed, Dec. 28; cost $1025.

Kansas near Salona. To build; owner, Mary E. Trowbridge; architect, J. T. Kidd; contractors, Blanchard & McKenzie; signed, Dec. 20; filed, Dec. 21; cost $1166.

Laguna near Grove. Alterations and additions; owner, Judah Boas; architect, M. J. Lyon; contractor, P. Maloney; signed, Dec. 29; filed, Dec. 31; cost $2850.

Market and Third. Galvanized iron tile for roof; owner, Phebe A. Hearst; architect, A. C. Schweinfurth; contractor, W. Heidt; signed, Dec. 22; filed, Dec. 22; cost $1300.

Market and Third. Babcock and Wilcox boilers; owner, Phebe A. Hearst, architect, A. C. Schweinfurth; contractors, Babcock & Wilcox Co; signed; Dec; 31; filed, Jan. 10; cost $13,144.

Allister and Franklin. Two three-story frame buildings; owners, Jos. and Christina Wannermaker; architects, Sailfield & Kohlberg; contractor, Jos. Bader and Jos. Fuchs; signed, Dec. 13; filed, Dec. 14; cost $12,750. Plumbing; contractor, Henry Hufschmidt; signed, Dec. 13; filed, Dec. 14; cost $1595.

McAllister near Fillmore. Additions; owner, Theresa E. Lee; contractor, C. V. McDonald; signed, Dec. 17; filed, Dec. 18; cost $1600.

Montgomery and California. Additions and alterations; owner, Thomas J. Clunie; architects, Curlett & McCaw; contractors, Duffey Bros; signed, Dec. 17; filed, Dec. 21; cost $2780.

O'Farrell near Jones. Three-story frame; owner, A. McFarlane; architects. Coxhead & Coxhead; contractors, Hannah Bros; signed, Dec. 31; filed, Jan. 4; cost $6470.

Post near Octavia. Alterations and additions; owner, Leonora M. Coleman; architects, Jesson & Holland; contractors, J. J. Jensen & R. Morgan; signed, Dec. 17; filed, Dec. 17; cost $1357.

Post near Laguna. Alterations and additions; owner, Jette Hamburger; contractors, Campbell & Pettus; signed, Jan. 4; filed, Jan. 5; cost $5620.

Pierce near Broadway. Two-story frame; owner, Maud Shirley Gregg; architect, Frank T. Van Trees; contractors, Williams Bros; signed, Jan. 8; filed, Jan. 12; cost $4420.

Scott near Pacific Ave. Two-story frame; owner, W. P. Redington; architect, E. A. Mathews; contractor, Edward Leiter; signed, Jan. 4; filed, Jan. 6; cost $7343.

Second and Mission. Fire proof floors, etc; owners, Wells Fargo & Co; architect Percy & Hamilton; contractor, Richard Keating; signed, Dec. 30; filed, Jan 3; cost $37,755.

Sixth Ave. near California. Six two-story frames; owners, Marcuse & Remmel; days work; cost $18,000.

Stevenson and First. Alterations and additions; owner, L. Schoenberg; architect, Sylvain Schnattacher; contractor, John Flaherty; signed, Dec. 13; filed, Dec. 16; cost $1040.

Stockton street and Stockton Place. Alterations and additions; owner, W. F. Wilson; architect, N. Blaisdel; contractor, R. C. Stifler; signed, Jan. 4; filed, Jan. 5; cost $1220.

Tenth near Howard. Two-story frame; owner, Cascade Laundry Incorporation architect, H. Geilfuss; contractor, F. W. Kern; signed, Dec. 22; filed, Dec. 22; cost $4500.

Van Ness Ave. and Clay. Fence work; owner, Claus Spreckels; architects, Reid Bros; contractor, S. F. Novelty Works; signed, Dec. 20; filed, Dec. 31; cost $1670.

Washington near Buchanan. Two-story frame; owner, Wm. L. Grestte; architect, E. A. Mathews; contractor, A. T. Ruch; cost $7674.

COUNTRY BUILDING NEWS.

OAKLAND

At the last meeting of the Board of Public Works, of Oakland, the plans of Cunningham Bros., architects of that city, for the proposed new fire station, were accepted.

The building will be a two-story brick structure, 40 feet front with a depth of 76 feet, in the Spanish-Renaissane style. The front will be of buff pressed brick, with red trimmings. The estimated cost is $7500. Bids are to be called for within a week.

AUBURN

Building operations in Auburn at this season of the year is not very brisk. A. L. Kennison is just completing a large building 50x70 two stories high, covered with "steel brick" siding. The lower story will contain a store, saloon and bottling works and upper story will be a dance hall. Cost about $3500.

Chas. Barker has just inclosed a neat two-story cottage; cost about $2000; architect, A. D. Fellows; owner Chas. Barker.

Guy Walsh has ready for plaster a neat one-story cottage.

E. B. Beecher will build a cottage on his ranch near town early this Spring.

S. F. Woodworth of Clipper Gap will build a soap and candle factory at Clipper Gap in the Spring.

Burt & Locher have purchased a lot and will erect a warehouse upon the same this Spring.

TUOLUMNE

The Board of Supervisors of Tuolumne County has accepted the plans of Wm. Mooser & Son of San Francisco, for a new Court House Building. The area of the main structure will be 89x47½ feet, and it will have a wing 30 feet square. The height to the apex of the tower will be 88 feet.

The edifice will be three stories, with the main edifice leading to the second floor. Stone will be used for the lower story, the walls above being in Roman brick. Construction will be commenced in April.

LOS ANGELES

Architect R. B. Young, in addition to the plans he has prepared of the Catholic church and parochial school at Pasadena, is now at work on the drawings of an academy, for the same denomination, which will be built on the school site on the corner of Walnut and Fair Oaks avenues. These buildings will be equal to any that have been erected in Pasadena during the past year.

The Los Angeles' Board of Supervisors have directed the clerk to advertise for bids for the construction of a tunnel through the divide at the head of the Poway grade in Sec. 35, twp. 14 south, range 2 west, in accordance with plans and specifications now on file in the county surveyor's office; the bids to be opened by the board upon February 9, 1898.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

☞ See a full size working model at our store.

411 MISSION ST., Bet. 1st and Fremont, SAN FRANCISCO, CAL.

BEST FOR WARM CLIMATES

Cannot Crack or Peel as Paint Does.

Being *in* the wood, and not wholly on the surface, like paint.

CABOT'S CREOSOTE SHINGLE STAINS

wear better and longer in warm climates than paint, which cracks and peels off under the hot suns. They are the only exterior colorings that do not turn black, and the only treatment that will prevent the blackening of Redwood. No other Stains can contain Creosote, "the best wood preservative known," our patent giving us the sole right to make, sell or advertise Creosote Stains.

The *Siding* of the Kip Mission, above, is Creosote Stained.

Samples and prices on application to

San Francisco, Depot: 421 Market St. CHARLES J. WATERHOUSE, Agent.

SAMUEL CABOT, Sole Manufacturer, Boston, Mass.

Also: Cabot's Sheathing and Deafening Quilt, Cabot's Mortar Colors, Cabot's Brick Preservative, Cabot's Anti-Pyre.

THE WEATHERWAX
PAT ENT SCREWLESS DOOR KNOB

SURPASSES ALL IN CHEAPNESS, DURABILITY AND APPEARANCE.
DOES AWAY WITH WASHERS AND SCREWS.
INSTANTLY ADJUSTS ITSELF TO ANY THICKNESS OF DOORS.
FITS ALL LOCKS.
SAVES TIME IN APPLYING, AND
CAN BE REMOVED INSTANTLY.

DIRECTIONS:

After Lock has been placed in position and escutcheon or roses have been screwed onto door, put the Knob Spindle through the Door, then put the Spring "B" in one of the Holes in Spindle; the free end of Spring should just clear the escutcheon or rose, when swung around, if too short move up one hole, if too long cut off with file or nippers, then put Knob on Spindle and press into place, when it will securely lock itself.

To remove Knob, insert a small awl into Hole "A" and press Spring down, at same time pull gentl yon Knob.

☞ Sample furnished on application to

Jackson east of Lake Ave. Alterations and additions to frame dwelling; owner, E. J. Lukens; architect, Clinton Day; contractors, Anderson & Greig; cost $9200.

Redwood Road, at Penniman Place. All work for a two-story frame residence; owner, Walter Morosco; architect, V. A. De Prosse; contractor, P. G. MacIntyre; cost $10,850.

Encinal Ave. SE cor. Chestnut. All work for two-story frame building, barn, shed, etc; owners, John L. and Hannal M. Ansel; contractors, A. P. Pattiani & Co; cost $4709.

BERKELEY

Blake Tract, lot 17, block B. Removal of 1st Baptist Church from present location to that given, and alterations in connection therewith; owner, Hartland Law; architect, Wm. Knowles; contractors, Kidder & Cooper; cost $3250.

Ellsworth Tract, lots 14 and 15. All work for a two-story frame dwelling; owner, Oliver Ellsworth; contractor, Frederick Esty; cost $4875.

BUILDING NEWS.

ALAMEDA

Park street, southeast corner Central Ave. All work for two-story frame church building; owner, First Methodist Episcopal Church; architects, Percy & Hamilton contractors, Thos. H., Chas. A. and Henry L. Day; cost $11,477.

Railroad Ave. north of Grand. All work, except brick work, foundations, chimneys and excavating, for two-story frame building; owner, P. N. Antoni; contractor, E. Young; cost $1425.

Seventh street, south of Pacific Ave. All work for a six-room frame cottage; owner, Kate C. Lubben; architect, E. H. Denke; contractor, A. R. Denke, Jr; cost $1675.

BELVEDERE

All work except plumbing and electrical work for two-story and attic frame hotel building; owner, Annie T. Moore; architect, Oscar Haupt; contractor, McLean Bros; cost $9925.

DECOTA

R. P. Hurlbut, a well known San Francisco contractor and builder, secured the contract to erect the Masonic Home at Decota, Alameda County. The amount is $43,510.

SALINAS

Another story will be added to the hotel building now in progress of erection at the sugar factory. It seems the building proved, even before the frame was enclosed, to be too small for future requirements. Hence the additional story is to contain 27 rooms.

SAN JOSE

Second street cor. William. Two-story frame residence; owner, G. E. Lombard; builder, F. D. Wolfe; cost $3150.

D. L. Steward and M. Kenney have secured the sub-contract for brick work on the Phelan Theatre Building, Z. O. Field is the principal contractor. The work will cost about $7500.

SAN DIEGO

For many years San Diego has been renting a building for a City Hall, and paying $3,000 per annum for same. It is now proposed to erect a new City Hall building at a cost of $25,000, the same to be placed in the centre of the plaza. In size, it will be 80x199. Experimental plans have been prepared by Architect C. A. Logan, showing how the property will look when improved.

BUILDING NEWS.

AUBURN

Bus ness at present quiet. Good rains will help us more than any thing else, though it looks as though building would be more brisk in another month. J. E. Walsh and Anderson Bros. will each build a cottage. Other work at present is mostly repairing.

CONTRA COSTA

George W. McNear is about to build a flour mill at Port Costa.

PALO ALTO

Two-story brick building. Owner, William S. Zeller; contractor, M. P. Madison; cost $13,885.

SANTA MARIA VALLEY.

A contract has just been let for the new sugar factory at Guadaloupe Lake, Santa Maria Valley. The contract is for $184,780, the plant to be finished by September 1, and to have a capacity for handling 500 tons of beets every twenty-four hours, and to be so constructed that it may be easily doubled in working power. Marschutz & Cantrell of this city are the contractors.

¡MEXICO

Consul-General Coney has received plans and specifications, calling for bids for a lighthouse-keeper's dwelling at Vera Cruz, Mexico.

LOS ANGELES

The Building Trades Councils of this city have passed resolutions demanding that buildings in course of erection be provided with flooring, temporary or otherwise, for the safety of mechanics working on the building and requesting that the regulations of scaffolding be enforced.

Architect Chas. L. Strange is preparing plans for Meyer Lissner of a two story building of eight flats, each containing six rooms, to be built on the corner of Ninth and Olive streets.

Architect John Parkinson is preparing plans for the American Building and Mortgage Co., of seven residences, two of which will be built on Ocean View Ave. in Knob Hill tract, and five on the corner of Bush and 18th streets.

Architect B. B. Bixby is preparing plans for Adam Boeck, of a two-story frame residence of eight rooms inside finish of yellow pine, plumbing, electric light and other modern conveniences, to be built at Redlands; estimated cost $2500.

BUILDING NEWS.

LOS ANGELES

Architect Edward Neisser has let the contract to T. C. Sears for the first of a series of cottages, to be built on the Woylhcott First street tract. The same architect has prepared plans for extensive changes to the front of the building occupied by Fox & Kellerman, on West Third street, near Broadway, that will cost $1500.

Architect Hugh Todd has prepared plans for the Lan Franco estate, of an additional story to the Central Block, on Spring street, near the corner of Court. The new addition will be occupied by the Order of Forresters, and will have three main assembly rooms, with the usual ante and property room; it will be constructed to conform to the present structure.

In view of the recommendations made by the grand jury, it is expected that the county jail will, at some future time, be converted into a hall of records, and a jail, with criminal courts and sheriff's quarters will be built on the county property, at the corner of Buena Vista and Temple streets.

At a meeting of the Trustees of the First Methodist Church, held Monday evening, it will resolve to receive competitive drawings for a new church building to be built on the northeast corner of Sixth and Hill streets.

The Edison Electric Company has entered into a contract with the Alcatraz Company for the construction of a complete conduit system throughout the business section of the city. This is in line with the ordinance passed by the council, requiring all electric wires and poles to come down by April 1, 1898. The letting of this contract practically decides that there shall be no "common conduit," but that each company will put in its own system. The expense to the Edison Company of establishing its plant here will exceed $150,000. Power is to be furnished by the Southern California Power Company, or Redlands Company, as it has been called. They have also purchased the Lichtenberger homestead, on East Fourth street, between Main and Los Angeles streets, where they will erect a power station and other necessary buildings for the transaction of their business.

The new Stimson Building is to be in every respect equal to the Wilcox Block, it will be erected on the northwest corner of Spring and Third streets. Architects Reid Bros., of San Francisco, are due to arrive in this city, and in a few days matters will be settled.

George W. Robinson will erect a $6000 frame building to contain flats, on South Flower St. Architect Thornton Fitzhugh, Byrne Building, prepared the necessary plans.

Ira Smith will erect a modern residence of 12 rooms to be erected on Adams street, near Figuerora. Architects Elsen & Hunt, Stimson Building, prepared the plans.

A four-story brick hotel building, 80x150 feet in size will be erected on Broadway, between 4th and 5th streets. Henry Martz is the owner, Krause & Jenkins are the architects.

Architect John P. Krempel is preparing plans, for A. Winstel, of a four-story and basement business business building 40x150 feet to be erected on the east side of Broadway, between Fourth and Fifth streets, adjoining the proposed new building of Henry Martz on the south. The front elevation will be of pressed brick and terra cotta, plate glass throughout the front. The building is designed for hotel purposes, and will probably be used in connection with the Martz building. The inside finish has not been decided upon. A union elevator will be put in for use in the duel building. The same architect has also prepared plans of a two-story stable and carriage house for the Oxnard Co., to be built at the factory site at Oxnard, Ventura Co. Also a station building for the Pasadena Pacific Co., to be built at Altadena.

Architect A. M. Edelman has prepared plans, for H. Newmark, of a four-story business and office bufiding, 60x150 feet, to be erected on Broadway, opposite the city hall. The front will be of pressed brick with terra cotta trimmings and marble entrance way; inside finish to be of oak; the building will also be supplied with steam heating throughout, and an electric passenger elevator will be installed. The same architect is also preparing plans, for A. Hamburger & Sons, of a two-story brick business building 40x98 feet, as an addition to their present place of business; it will be built on the east side of New High street, near Franklin street.

ALTADENA

A contract has been let for the erection of a two-story frame dwelling for H. D. West. Consideration, $6449. This does not include the painting, plumbing or mantels. Blick & Moore of Los Angeles, architects; D. W. March, contractor; Horatio D. West, owner.

VOLUME XIX. FEBRUARY 20th, 1898. NUMBER 2.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

SINCE the publication of the last issue, the California Architectural Publishing Company of San Francisco have leased to E. H. Burrell the right to publish THE CALIFORNIA ARCHITECT AND BUILDING NEWS.

Mr. Burrell has for many years been connected with the fortunes of the paper in a business way, and as one of the Directors of the Publishing Company. He will have charge of the business department while for the literary end of its affairs Tom M. Grant will be responsible. A co-partnership having been formed to do business under the firm name of E. H. Burrell & Co., the financial responsibility falls equally upon the shoulders of the partners to the firm—Messrs. Burrell & Grant, who will continue at the old stand, 408 California street.

As to the policy of the paper in the future, it is a certainty that just a trifle more direction and just a trifle more energy, will be infused into its columns under the new regime, while it is equally as certain that outside issues and isms which have no bearing upon nor any part in a Journal devoted to Art, Architecture, Archæology, Engineering and Decoration, will be rigidly excluded.

In this connection it will not be out of place to mention some of the objective points, that in season and out of season will receive considerable attention and unyielding suppor in these columns.

First on the list, because of its far reaching importance, is the passage of a State Law providing for the licensing of architects and regulating the practice of architecture as a profession. Second, the unconditional repeal of the Mechanics Lien Law. Third, compliance on the part of contractors with the rules and regulations as prescribed in the National Electrical Code for the installation of wiring and apparatus for electric light, heat and power, and enforcement thereof by every architect who is a reader of this paper.

The illustrations will be in keeping with the same spirit of liberality and excellence that has characterized them in the past but ever improving by and through the assistance and co-operation of those of our readers who possess the magic touch and willing hand with the pencil.

To place this paper—the only Journal of its kind published on the Pacific Coast—in the front rank of its class in these United States, is the real ambition of its publishers—and to that end and that end only shall all of our efforts and all of our energy be bent.

FIRE UNDERWRITERS and the California Insurance Department entertain very different views of the laws of the State, and will settle their differences in the courts. The commissoner's rulings have attracted the attention which it is evident he desired they should, for he has even gone so far as to furnish the daily newspapers with copies of his letters to underwriters before they could be delivered through the mail. This was hardly a dignified course to pursue.

Some of the commissioner's demands are indefensible. They are absurd to the verge of puerility. The sound, respectable companies will not comply with them, and a number of the largest and strongest companies can not. What can be more ridiculous than to require foreign and eastern companies to keep a San Francisco daily record of all transfers of capital stock in Hartford or London? Nothing, excepting perhaps the commissioner's demand that a company with $50,000,000 surplus should increase its capital stock from $100,000 to $200,000 in order to make its contracts as good as companies with $200,000 capital and only $50,000 surplus.

Many foreign companies have a good deal of subscribed capital stock not paid up. The commissioner professes to hold that this unpaid proportion give these foreigners an illegal "advantage" over California companies, and he has ordered that the unsubscribed proportion be paid up forthwith. Such an order cannot, of course, be complied with.

If the courts should sustain the commissioner in his extreme position, the effects will be very damaging to business interests. Many insurance companies would be compelled to withdraw from the State, and cancellations of policies would be general. Fire insurance is so intimately related to commerce that if its sustaining contracts are withdrawn business generally must be suspended. Building operations would have to cease. The banks would not lend money. A great deal of property would remain uninsured, and fires would cause bankruptcy. Thousands of men would be thrown out of employment.

The office of insurance commissioner has too much authority, since it is possible to provoke such disaster. A dishonest or cranky official, unrestrained by mandamus proceedings, can drive out the most solvent companies or force them to pay him tribute. The object in the creation of the office was merely to give assurance of solvency and to eject and exclude insolvent companies. It was never contemplated that an insurance commissioner should use the power of the office to annoy and hamper ligitimate companies, or to pose in the daily press as a Don Quixote smasher of wind-mill trusts.

For the sake of the business interests of the community it is to be hoped that the courts will teach Mr. Clunie his proper place. A bull in a china shop can do a great deal of harm.

IN CONVERSATION on internal affairs of building and loan associations, an authority in this line says that it is a debatable question as to whether it would not have been better for the cause, that premiums for money loaned had never been injected into the laws under which they operate. In the past they did add materially to the gains, but now but little. They have invariably tended to mystify the borrower and lead to more or less confusion and misunderstanding. The simple payment of dues and legal interest, monthly, in fixed installments, is readily understood and the borrower is satisfied. To pay interest on money retained as premium was never popular but was accepted because it was an established custom at the beginning of the successful era of building societies. Conditions have changed and the earning power of money has likewise, and the sooner the building society managers comprehend the fact the better. There was a time, and not very remote, when the circumstances probably did warrant premiums, but not now. The investor in a society receives a larger rate of interest for his money than if placed on deposit in a trust company or savings fund, and it is this that induces him to put by his earnings. Even if the rate of interest for loans was lowered, and the gains lessened, the borrower would be better off, and the investor at the same time, receive a larger rate of interest than paid him elsewhere. If lower interest would bring better loans, and place the associations on a stronger financial basis it would materially increase their popularity.

THE ELECTRICAL WIRING OF BUILDINGS.

THE FLATTERING manner in which the first paper on the above subject has been received by the progressive architects is assuredly a matter of credit alike to the forethought and enterprise of the paper's new management and to those of its readers who are able to see their weakness and seeing it are not only willing but anxious to absorb strength and enlightenment from any ource that offers that of which they may be lacking.

There are contractors and contractors in this electrical wiring work, and evidence is accumulating in this office which at the proper time and in an indisputable shape, will be placed in the possession of the S. F. Chapter of the A. I. A. Many of these so-called contractors are fakers pure and simple, but the day is at hand when as a matter of self protection no self respecting Architect will permit one of these worthies to figure upon any work that is to be given out of his office.

In the development era of ten or more years ago, everything connected with electrical matters was in an experimental stage bordering on the chaotic, and these fake contractors flourished and prospered. But the unprecedented proportions that the business has assumed each year, forced the growth of experience into like proportions, with the result that the corps of alert and inventive workers were numbered by the tens of thousands. This has brought the business of the installation of wiring and of the manufacture of apparatus for electric light, heat and power down to an exact science.

Then to whom is an knowledge of this exact science more important than the Architect—surely to no one, for since our last issue the Phelan Building, on Market street has had a close call from annihilation by fire—cause—defective and careless wiring for electric lighting of the top floor of the building. Here then, Architects, have a fine object lesson, furnished to order almost. The wires were run up the elevator shaft, in the mouldings, to the attic, and then up on each side of the iron rods that supported the roof truss, and across the truss to the distributing board for the top floor.

These iron rods were bolted through an iron plate thus forming a complete circuit between the wires. No signs of bushing could be found on the wire where it crossed the iron rod in the centre of the truss—and it is more than probable that the neglect of the electrical contractor to bush and tape that wire, at that particular spot, was the real cause of the fire in the Phelan Building.

The narrow escape of the Phelan Building has brought to the attention of this Journal as foul and criminal a piece of electric wiring as it is possible to conceive the most depraved and greedy mind of man contriving at.

The Powell street theatre, as at first wired is referred to, and it was not until the interior of the theatre was being remodeled for the Stockwell lessees that the discovery was made—that for all those preceeding months, the pretty little theatre had been a virtual deathtrap—unknown to everyone, always excepting that evil minded contractor who perpetrated the fraud and made possible a holocaust in the midst of a trusting community.

This contractor, who is still in the business—used in that theatre rolls of brown paper painted black, where bushings were required—to save the cost of the hard rubber bushings specified. These rolls of brown paper—were all hidden and it was also discovered that all the wiring that was hidden was of the very cheapest variety with insulation that was absolutely worthless. It was only wherever the wires were brought through and exposed that they were found to be of standard requirements.

To be Continued.

SPANISH HYCIENDA.

RENT SPACE IN OFFICE BUILDINGS.

FROM THIRTY-FIVE TO FORTY-FIVE PER CENT OF THE GROUND AREA NEEDED TO SECURE DAYLIGHT.

MOST PEOPLE have but a vague idea of the comparative cost of construction and the comparative amount of rentable space in new and old style office buildings. As to cost, the amount, of course, varies greatly according to the inclination and the means at the disposal of the owners. They may simply be content with putting up a good, serviceable structure, with plain every day finish, or they may be bent upon attaining the height of elegance in finish as in convenience. A writer in the *Chicago Times-Herald* in a clever paper gives some good points on the subject from which quotations *ad libitum* are made:

"A fair estimate of the cost of construction of a first-class modern fireproof office building, according to a well-known constructive engineer, is in the vicinity of $3 a square foot of floor space. Thus, a ten-story building, 50 by 100 feet, being 50 by 100 by 10, or 50,000 square feet, can be constructed for $150,000.

Prior to 1880, before the general introduction of what is now known as the Chicago construction, with elevator and steel skeleton, $1 per square foot of floor space was a fair estimate. Office buildings then were mostly four and five stories in height, and floor space was not so much subdivided as in modern structures. The principal elements of cost were labor, bricks, cement and framing timber. The price of labor and bricks has remained about the same, that of cement and framing timber has fallen. Iron and steel are, of course, much cheaper to-day, but these materials did not enter very largely into the construction of non-fireproof structures.

"As to rentable floor space, the general reader will no doubt be much surprised to learn that it takes from 30 to 45 per cent of the ground area of the building lot to procure daylight for all parts of the structure. On this point the authority cited says:

"'As to rentable floor space, the following percentages of the gross area should be available for office uses: In a corner building, 25 by 100, 70 per cent; in an interior building, 25 by 100, 55 per cent; in a corner building, 50 by 100, 72 per cent; in an interior building, 50 by 100, 64½ per cent; in a corner building, 100 by 100, 62½ per cent; in an interior, 100 by 100, 55 per cent. These percentages, however, are attainable only in buildings planned according to approval principles of engineering and architecture, and have not by any means been reached in all modern structures. I should say that 60 per cent of the gross floor area is a fair estimate for the rentable space in modern buildings, as against 70 per cent in the old. The difference is due partly to the presence of elevator shafts and an increased number of partition walls, but especially, perhaps, to a more perfect compliance with the demands of sanitary science.

"'For example, much space is devoted to light courts, proper light not being obtainable in offices beyond say twenty-five feet from the windows. In this, as in other respects, the sanitary condition of the office renter is vastly better to-day than it was seventeen years ago. The consequence has been a tremendous increase in operating expenses, for the landlord is obliged to furnish a thousand and one

conveniences and services not thought of before. Of the average cost of operating modern office buildings, it is impossible to give anything like a fairly accurate estimate. Faulty designing is a frequent source of unnecessary expenditure. I know of buildings of the same size and equivalent hours of service in which the weekly expenses of the one equal the monthly expenses of the other.'''

NATURAL BUILDING STONES OF THE PACIFIC SLOPE.

GRANITE

THE FACT that the principal cities of the Pacific Coast, and especially San Francisco, have reached the stage of permanent improvements in sympathy with the general commercial developments of the whole country, has naturally awakened a general interest in the discussion of the relative merits of our natural resources in building materials. It has long been known in a general way that California is at least as rich in such resources as any region in the world; but it is not generally known that if half the capital and energy that is now devoted to the search for precious metals were devoted to the development of our quarries, the profit to individuals and the gain to the whole community would be larger.

In discussing the relative merits of different natural building materials, granite comes first. Because, though geologically not the oldest of all rock, it is in all essentials the best for certain purposes. It is free from the cellular cavities of all trappean and volceanic rock, with a larger proportion of quartz than the later igneous rock. Composed of feldspar, quartz and mica in confused crystallization, it is the strongest of all building material in resistance to crushing and all other tests. With these qualities it is not remarkable that the demand is greater than for any other stone; the output in the United States reaching an average value of twenty million dollars annually—while the average for the past five years is much greater.

In any permanent building some granite is used, whatever other materials may be superposed; because its wearing qualities as well as its strength, exceed all other materials. The only buildings that have survived for four thousand years or more are granite buildings; and except where fire, violence, or the ebrasion of drifting sand, has made some impression, the carved detail is still as sharp as when it was first executed. Granite is however as various as other materials according to its local peculiarities. The proportion of the different properties, the relative and actual size of the crystals, the cementing material in the interstices, and the color of the quartz, all must be considered in comparing the merits of different granites. In a general way it may be said that as a matter of strength and durability, the smaller the particles, or crystals, and the whiter the quartz, the better—and again: the less lime there is in the cementing. In short granite is an ideal concrete, that nature has kept under a tremendous pressure for innumerable centuries—and she has made it in so many varieties that we are not restricted o mere sombre tones in realizing our designs and desires; but can avail ourselves of beautiful contrasts and harmonies of color. We have the large variety of greys, light and dark, brownish, yellowish or greenish; and nearly white, and the whole grade of reds, to rose pink; the decided greens, and the blues. And all these can be darkened and intensified by polishing—all of the peculiarities of granite being that a polished surface retains its polish under almost all conditions. The exception is where the red or pink granites are exposed to the corrosive action of the atmosphere of manufacturing towns. In such cases the protoxide of iron in the quartz is affected and disintegration sets in. In general the colored varieties of granite have larger crystals than the colorless varieties; but as they are generally selected for decorative reasons, the difference in the comparative strength is not important. California has only begun to develop her granite quarries, but there are already several whose facilities and management are equal to any demands that can be made. That is to say, that these facilities exist in working order to execute several contracts on time, each as large as would be involved in our promised Post-Office.

There is no limit to the size of the blocks that are obtainable in granite, but the practical limits in handling. Our mechanical resources are probably greater than the world has ever known; and if the time shall ever come when for

some object we are willing to meet the necessary expense, we can quarry and transport larger blocks of granite than were ever attempted in Egypt. It is not claimed that California furnishes every variety of granite known, but she furnishes a greater variety than any other region. Each locality has some distinctive peculiarity owing to local influences—the large crystal, blue, and rose colored granites of Aberdeen have not yet been discovered but there is no reason why they should not be, and mean while the people

are not yet wise enough to use what they have for all it is worth.

This short sketch of a very large question is intended merely to arouse interest and discussion, and it is to be hoped that the readers of this Journal will not hesitate to write any queries that are suggested—when answers will be published with the next issue. It is promised to give each month a short treatise like the present on some variety of building stone, and together with a general description, to give some simple rules and suggestions for experimental tests that can be applied without special apparatus or education.

[The Editor is not responsible for anything which appears in this column.]

THE following letters regarding the Concrete floor test at Wells, Fargo & Co.'s new building are self explantory:

THE PACIFIC COAST BORAX COMPANY,
NEW YORK HOUSE, 185 WATER ST.

NEW YORK, Feb. 17, 1898.

To the Editor of the California Architect and Building News.

SIR:—In reference to your article on Fire-Proof Concrete tests in your January issue we desire, through your courtesy, to place before your readers the following facts:

First—We were not invited to participate in the test in anyway. We were entirely unrepresented.

Second—The slab supposed to represent our system, as described by you, was not built as we would have constructed it. The construction was faulty.

We would inquire through you: 1st—If the other system was not represented by an accredited agent. 2d—Who built the slab that was supposed to represent our system.

Yours respectfully,
SMITH & RANSOME CO.
Per Ernest L. Ransome, Pres.

WESTERN EXPANDED METAL AND FIRE PROOFING CO.,
CLAUS SPRECKELS BUILDING, ROOMS 114–15–16.

SAN FRANCISCO, CAL., Feb. 24, 1898.

California Architect aad Building News.

GENTLEMEN:—Your favor of even date, together with Mr. Ransom's letter, are at hand, and in reply, we will say that we furnished the No. 16 guage 2 and ½ inch mesh expanded metal for the test referred to, at the request of Mr. G. W. Percy of Percy & Hamilton, Architects.

This Company paid no further attention to the construction of the slab, as the matter was left entirely in the hands of Mr. Percy and his workmen, and we do not even know what mixture was used and did not know when the test was to be made until notified by Mr. Percy the evening before, to be present the next morning at ten o'clock, at which time General S. W. Backus, secretary, and myself, together with many others, witnessed the test referred to in your Journal.

Very truly yours,
Western Expanded Metal & Fire Proofing Co.
Dict. N. L. B. N. L. BELL, Manager.
CUSHING, WETMORE COMPANY, 508 California St.

SAN FRANCISCO, Feb. 25, 1898.

California Architect and Building News.

GENTLEMEN:—In reply to your favor of the 25th inst., requesting information in regard to concrete slabs built at Wells, Fargo & Co.'s new building, we would say that the slabs were built by us under instructions received from Messrs. Percy & Hamilton, Architects, and under the personal supervision of Mr. James Humphreys, superintendent of construction. The iron and metal lath were furnished us at the building and no agent of neither method was present during the construction of the slab, either did we follow any instructions other than those given us by Mr. Geo. W. Percy and Mr. Humphreys. Very respectfully yours,

Cushing Wetmore Co.
Per Goerge P. Wetmore.

THE Report of the Metal Lathing test, as printed in our last issue, seems to have been anything but satisfactory to the writer of the following letter:

To the Editor of the California Architect and Building News.

DEAR SIR:—In your last issue there appeared a statement which read as follows:

"On Wednesday, January 26, an interesting test was made at Wells, Fargo & Co.'s building designed to show the relative merit of different kinds of metal lath and other materials * *. It was intended to test four different kinds of metal lath in the chimney, but the representative of one kind became dissatisfied and wished to prevent the test being made."

Now then let me here inform your readers the reason why the owner and inventor, Martin Carrick of that "one kind, that became dissatisfied," but whose lath proved itself to all who witnessed the test, to be superior to the others, notwithstanding the disadvantages to which it was subjected, the principal one being the manner in which the coat of mortar was put on, which I boldly assert was not equal in body or workmanship to that which was given to the other makes contesting.

Still, when all the others were scorching and smoking, and long after the wire lath that had already been awarded the contract for the building, was in a blaze, it stood its ground nobly and will stand for all time.

I will now give my reasons for objecting to a test being made on my lath, and I will ask any fair minded man to place himself in my position and see if he would not do as I did under the same circumstances.

Last October I figured on the fire-proofing construction of the new Wells, Fargo & Co's Building, now in course of erection on the corner of Second and Misson streets. Each contractor who was invited to figure on the work, was instructed to submit his own sketches and complete specifications, in order to show the architect how he would perform the fire-proofing construction on said building.

Bids to be submitted on the 13th day of above month at noon sharp. I handed in my bid, sketches and specifica-

tions at the hour and place mentioned and waited developments. Let me say right here, that after several weeks deliberation over the plans and specifications of the selected contractors, the architects made up their minds to make several changes in the fire-proofing work for the building—so they swept aside all bids, plans and specifications that had been submitted and called for new ones, but I was not favored with a second invitation to bid.

Two weeks passed by without hearing any more about the matter, being anxious I decided to call down to the new building, to get some information regarding the work I had figured on; I was met by Mr. Wetmore the contractor for the concrete work, who said to me "Mr. Carrick I am requested by Mr. Percy to ask you if you will be willing to go into a contest with your lath; and furthermore if you will pay your part of the expenses of preparing a furnace to test the different kinds of metal lath?"

My answer was, "all things being equal I was willing."

I called on Mr. Percy in a day or two after that and he said he was going to make a plan of the furnace, and that he would let me know in time, he also said he had "no ax to grind" with anyone; I thanked him and went away. I heard nothing more about the matter until about the first or second of December when I met Mr. Percy on the way to his office, he asked me to walk back with him and he would let me have the plan of the furnace. I got the plan and made panel according to the directions.

We then came to a stand still again until about the 16th of December, when I received a postal informing me that the panel and lath I had prepared for the test was required at once. I delivered them as ordered and all went well until the 4th day of January, when to my great surprise, there appeared in a morning paper of that date, the news of the awarding of the contract to Mr. Keating for the fire-proof construction on the Well, Fargo Co.'s new building for which I thought I was competing and that, more than that, the test which had not yet been made was to be a part of the competition.

In the name of common sense, what interest or gain, was I to receive from that building after the contract had been awarded to another. The day after the news was published I called at the office of Messrs. Percy & Hamilton, for my plans and was told that they had disappeared and that they could not be found, so taking all into account, I think my reasons were well founded and sufficient for taking the stand I did.

In conclusion let me here state, that I wish all who witnessed the test and those who may have read the account in the California Architect, to distinctly understand that I never for one moment entertained any fear as to how my lath was going to stand in the test, I was well aware that it would come out on top, and was ready to put up $100.00 or $500.00 that my lath would outlast the others in any fire-test, all things being equal. It is the invention of a practical plasterer, and is manufactured here in San Francisco.

Respectfully, Martin Carrick.

NOTICE TO ARCHITECTS.

THE BOARD of Managers of the Mendocino State Hospital invite competitive plans and specifications in detail for the erection of an administration building to be erected on the premises of the said Mendocino State Hospital, near Ukiah, in the county of Mendocino, State of California to cost $58,800, including the sum of twenty-eight hundred dollars premium for the plans and specifications adopted and supervision of the erection of said building to completion.

The plans and specifications must be delivered on or before 2 o'clock P. M. of the 19th day of March, 1898, to W. W. Cunningham, secretary, at Ukiah, California.

The Board reserves the right to reject all or any of said plans and specifications.

Further information may be had by applying to W. W. Cunningham, secretary, at Ukiah, Cal.

JANUARY UILDING.

WE ARE indebted to the *Builder and Contractor* for the following summary of building operations at Los Angeles. During the month of January the Superintendent of Buildings issued 161 permits, amounting to $219,325, viz:

108 new buildings, stables, etc	$198,060
39 alterations and repairs	19,355
14 removals	1,910
161	$219,325

Which are classed as follows:

Frame cottages	45
Two-story frame residences	37
Brick and " "	1
One-story brick buildings	8
Three-story " "	1
Warehouses	1
Factories	1
One-story frame stores	4
Stables and sheds, etc	10
Additions and repairs	39
Removals	14
Total permits	161

The Plumbing Inspector issued, during the month of January 268 plumbing and sewer permits.

The County Recorder's office shows 49 contracts filed during the month of January, amounting to $190,891, which are districted as follows:

Los Angeles	42,	amounting to	$167,560
Pasadena	1,	"	4,200
Altadena	1,	"	6,449
Garvanza	1,	"	3,633
Glendora	1,	"	1,345
Azusa	3,	"	7,704
			$190,891

COMPARATIVE BUILDING.

THE FOLLOWING totals, showing the number and amount of the building permits issued during the months of January for the past three years and the present, will be interesting to those who think that the building boom has come to an end:

January, 1895—	Permits issued,	165;	amount		$180,000
" 1896—	"	"	160;	"	244,191
" 1897—	"	"	138;	"	126,020
" 1898—	"	"	161;	"	219,325

By reference to the following table, it will be seen that Los Angeles presents a very favorable showing in a list of some of the principal cities of the union.

CITIES	1896	1897
Chicago	$22,730,615	$22,777,230
St. Louis	10,190,898	9,471,640
Pittsburg	5,591,300	6,899,118
San Francisco	5,673,998	4,460,117
Detroit	5,465,228	4,385,840
Los Angeles	3,805,175	3,660,175
Indianapolis	2,387,864	3,445,047
Cincinnati	3,110,415	2,486,890
New Orleans	3,257,643	1,619,285
Omaha	2,402,591	1,448,776
Kansas City	1,900,458	1,848,390
Denver	1,305,872	1,265,300

INTERIOR VIEW—WEST END—TEMPLE MISSION LODGE NO. 169 F. AND A. M.

HERMAN & SWAIN, ARCHITECTS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

ITH this issue we present four illustrations taken from the Brochure Series of Architectural Illustrations, published by Bates & Guild Company, 13 Exchange street, Boston. From the Brochure we reprint the following descriptions of these engravings:

THE Arch of Titus, Rome.—If not the first, certainly one of the earliest examples of the elaborate architectural style in which the triumphal arches were carried out, is the arch of Titus in Rome. Built by the Roman senate and people to commemorate the destruction of Jerusalem in 70 A. D., it was not finished until after the death of Titus in 83, though it was doubtless begun during his life. During the Middle Ages it was made a part of the fortress tower of the Frangipani, and was not isolated until 1822.'

In composition it consists of a single opening framed by the composite order, and is said to be the first ever erected in which that order was employed. Whether or not that be true, itis certainly a graceful example of it, and has been treated as a model of its kind. It is built of large blocks of Parian marble, and is simple in outline and in excellent architectural taste. The archway is flanked on both faces by two engaged composite columns on each side which support the entablature. The frieze is sculptured with sacrificial processions. The shafts gradually diminish from the pedestals, and are surmounted by the usual acanthus capitals. They are doubtless originally all alike, though the outer columns have been restored in a manner unworthy of their old companions. The volutes, and in short all parts of the capitals as well as the details of the entablature, are in a style of profuse ornament. The spandrels are filled by two Victorys; one holding in her hand a standard, and the other apparently a laurel crown. The brackets under the cornice are formed of dolphins resting upon shells. On the keystone, now much decayed but once deemed the finest in Rome, are relics of a helmeted female figure, probably Rome herself.

The famous reliefs of the "Spoils of the Temple" are to be found on the walls of the interior of the passage. The sculptures are now much worn, but may still be recognized by their beauty and vigor as belonging to the first era of Roman art. The attic which surmounts the whole and bears the inscriptions is overpoweringly high, and perhaps detracts from the beauty of the general proportions. The absence of sculpture on each side of the arch is also a defect; for the only logical function of these monuments is to present surface for sculptured decoration. Yet, as a whole, the arch of Titus is certainly the most remarkable in Rome for harmony of proportion and beauty of sculpture.

LIBRARY of the Vatican, Rome.—The Vatican Library was founded by Pope Hilaire I., in the fifth century, and has been enlarged by each of his successors. It occupies one of the wings of the Vatican Palace adjoining the museum and the portion of the building designed by Bramante. The books are arranged in closed cases standing against the piers and wells. The decorations are of the richest type of the Italian Renaissance.

GALLERY of Henry II, Fontainbleau.—The ball-room or gallery of Henry II. is by many considered the masterpiece among the interiors of the French Renaissance. It is 97 feet 4 inches long and 31 feet broad. It has a beautiful outlook on one side upon the gardens, and on the other upon one of the courts, through large arched windows five on each side, having no architraves, occupying the whole space of the alcoves which are 8 feet in depth, separated by piers 7 feet in width. These alcoves are surrounded with seats 13 inches in width and 20 inches high. The wainscot, 8 feet 6 inches high, is of quartered oak with no finish whatever, probably planed and scraped, but not so smooth as would be made by sandpapering. The mouldings and flutes of pilasters are gilded with dull gold. The abundance of light gives an added value to the magnificent decorations of the walls and ceiling. The caissoned wooden ceiling in octagonal panels with rich carved mouldings is of quartered oak of the same color as the wainscot, enriched with gold and silver, the field of the octagonal panels in gold. The polished oak floor laid in an octagonal pattern, seems to reflect the sumptuous design of the ceiling, and from its finish and lack of gold, is a little darker in tone. The walls as far as the frieze, are covered with paintings, low in tone, and of a general effect, containing the emblems of Henry II. and Diana of Poitiers, surrounded with frames of gilded mouldings. Serlio, the architect of this room, designed to cover it with a vaulted ceiling, and the corbels for the springing of the vault may be seen on the piers, now serving to support branching chandeliers. The frieze is a mass of mythologic and ideal figure compositions. The vaults and walls of the bays or alcoves are similarly painted, although with broader and simpler designs. At one end of the room is the musicians' gallery, and at the other the superb mantel shown in our illustration.

The freshness and wonderful preservation of this room are at first sight astonishing. Decorated by Primaticcio and Niccolo dell 'Abbate, between 1552 and 1557, how does it come to be in its present perfect condition? It has been retouched and repaired at various times since then, and has suffered from the would-be improvements of decorators, but was all thoroughly restored in 1834 by Alaux, whose skill and painstaking research have given us a very close approach to the original room.

BED of Mme. De Maintenon, Fontainebleau.—This little room, 12 by 14 feet, is light and cheerful in effect, and simple in design. The walls are finished in grayish white with mouldings and ornaments in dull gold. The furniture

is all of gold with fillets and ornament burnished, and is covered with grayish white silk, lighter and warmer in tone than the walls, with patterns of colored flowers. The foot of the bed is covered with white silk, and the hangings are all of white silk, with a border of yellow, light green and rose.

IN THIS number is illustrated the new Temple of Mission Lodge No. 169 F. and A. M. situated on the west side of Mission street, between 22d and 23rd streets, Hermann & Swain, Architects.

The building occupies a lot 54x125 and is two stories in height in the front portion and three stories in the rear. The building is of fire-proof construction and is provided throughout with all modern conveniences in the matter of heating, lighting, ventilation, plumbing, etc.

The exterior facade is in the Italian Renaissance architecture, executed in buff, Roman brick and cream terra cotta with red tile roof, the whole presenting a pleasing combination.

In the basement is located the heating and ventilating plant, motor and electrical apparatus, the Morgan system being used.

The first story contains two large stores. The main entrance to the building is finished with Tennessee marble dado and mosaic floor and the ceiling of same, paneled in oak.

The second story contains one lodge room, 26x40 in size with two capacious ante rooms.

Also the Masonic Hall 43x63 ft. in size and 22 ft. in height with 7 ante rooms and organ loft in connection with same.

The corridors and stairways in the two upper stories are finished in hard wood with ornamental copper dados, five feet high, all doors and finish being also of ornamental copper. All the antique copper and metal work of the Temple is in keeping with all the metal work done by the well-known house of Jas. Gilfoy & Sons of 208 Eighth street.

The interior of this Masonic Hall is finished in ornamental copper in the most elaborate manner, no expense having been spared in making it the finest hall on the Pacific Coast.

The general finish of this room is in the Roman Corinthian order with massive fluted pilasters on the North and South walls supporting the heavy beam finish of the ceiling above.

The central portion of the ceiling is in the form of a circular dome with 235 incandescent lights, 115 of which are worked into a colored star.

The gas and electric fixtures were selected by the committee in charge, after a most thorough canvas in the market. Designs were submitted by the several firms competing. Mr. Chas. F. Kinsman whose office is in the Claus Spreckels Building succeeded in pleasing all concerned. The same are of novel and neat design, of eastern manufacture, and show in each fixture quite a departure from what are seen in most buildings of this kind.

The Master's station in the East is in the Roman Corinthian order of architecture, with the rising sun in cut glass set in the pediment which is emblematic of the Master's office.

The Senior Warden's station in the West is in the Grecian Ionic order with the setting sun in cut glass set in the pediment, the same being emblematic of the S. W. office.

The Junior Warden's station in the South is in the Grecian Doric order with the meridian sun in cut glass set in the pediment, the same being emblematic of the J. W. office.

The station in the North is the Tuscan order. The cut glass suns in the various stations are lighted with incandescent lamps.

The two golden pillars in the West end of the room were modelled after the pillars in the North Portico of the Great Hall of Xerxes at Persepolis, being the nearest known examples of the two bronze Jachim and Boaz, which were the principal ornaments in the facade of the Temple of Solomon.

These two pillars of Solomon's Temple being of metal were probably much finer in detail and more elaborate in ornamentation than their prototypes of Persepolis, but as we have no other actual examples to compare with, the restoration may be somewhat fanciful.

The carving on the pillars was executed by Frank T. Riley of 528 Fifth street, who was also awarded the contract for the spheres, Celestial and Terrestrial, that are mounted on the two pillars as shown in illustration of West End and Senior Warden's Station.

The treatment of the walls, ornamental stucco work and ceiling of this hall is in blue and gold.

The third story contains the spacious banquet room, seating 200, and also smoking room, janitors' quarters, store rooms, etc.

The furniture, fittings and hardware were all made to order from special designs.

The plumbing work throughout is of the very best, all modern conveniences being provided for in the specifications; the work was done by the "old reliable" firm of Wm. S. Snook & Sons of 554 Clay street, where the "Lilly" closets, from the works of the John Douglass Company are to be found very much in evidence when wanted.

The excavations were made by the John Kelso Company. The California Art Glass Works are responsible for the cut glass Sun bursts and Wm P. Fuller & Co. supplied all the window glass used in the building.

The cost of building, exclusive of site, was $30,000.00.

THE FOLLY OF PRICE CUTTING.

IF ANYBODY is in doubt of where profits sometimes go in producing stone for building, let him consider the price at which Georgia marble has been sold for the new Minnesota Capitol—75 cents a cubic foot, delivered at St. Paul! It is said this price will not net the quarrying company over 21 cents, after delivery charges are paid. Out of this meager price must come cost of quarrying, loading, interest charges and other fixed and incidental expenses always attached to a large production, and the *profit*. It is safe to say it won't take a very large bag to hold the latter. An excuse for the low price is given that "the marble company wanted the advertisement which this structure will give it." As for the result, if the motive is correctly stated, there can be no doubt. The new capitol will be a magnificent exhibit of the splendid qualities of Georgia white marble, and a perpetual advertisement of the company that furnished it. *But*, and here is where the evil of such a bid comes in—the selling price of the marble has been marked down below the point where there is any reasonable profit. If this great producer setsthe example of unprofitable selling prices, competing producers must meet its terms—and a warring over prices will ensue at every contract letting—and we will have the pitiable example of Bedford limestone interests repeated in the strife thus engendered among the Georgia marble producers.

There may be profit in it for the Georgia Marble Company at 21 cents per cubic foot at the quarry, notwithstanding the added value of the advertisement, and the transaction may be, and doubtless is, a perfectly satisfactory one; there may be profit to the Bedford quarryman who sells his No. 1 stone at the quarry for 12 cents a cubic foot; but while contractors and builders are not falling over each other in a scramble to get orders on file for their product, it dosn't seem to us that it is the best for the future of Georgia marble or Bedford stone to cut so deep while the system is in an enfeebled condition. To do so brings onto a level these superior products with the inferior from every quarter. That's something very hard to overcome, particularly if there are any politics in the jobs. We believe defeat has often been met at lettings of important works just because the cheap price at which good stone has been offered was considered by the board good evidence of a degraded character. Like wages, when the price of stone is put down, it is almost impossible ts put it back. Better keep it at a profitable price, and create a demand for it by judicious advertising, than to sell it at a loss, and trust in the advertisement to establish the profitable price. It is well to bear in mind that there are other holes in the ground thanthe one you are digging in.—*Stone*.

WE ARE indebted to *The Investigator*—one of Chicago's brightest papers—published in the Insurance interests—for the Jenny paper together with cuts for illustrating the same.

FIVE hundred thousand dollars has been set aside by the committee on Appropriations, for the S. F. Post-Office Building and the Supervising Architect has decided against experimental contractors for structural material. Granite and granite only will be used all reports to the contrary notwithstanding.

THE USE OF SCULPTURE IN ARCHITECTURE.

WITHIN the past four or five years our buildings have gradually become more ambitious and ornate in style, due, perhaps, to an attempt to evolve something which shall hereafter pose as a standard of excellence. Carvings more or less elaborate are being introduced to a greater degree and, of course, when they are properly arranged in position their effect is harmonious and inspiring. But nowhere save in the East has there been, as yet, an attempt at harmony or judicious arrangement.

The Western architects, almost to a man, have heretofore relied almost solely upon the fact that a certain amount of plastic decoration is required, and in consequence without taking into consideration any method or scheme of arrangement, they have simply dotted over their exteriors with incongruous and fantastical ephemeræ which lack both necessity and meaning.

Art is ideal; and ideality is emblematic of something which has realism for the body and spirituality for the soul of that body. Of course this is less typified by an architectural composition than a creation delineated by means of any allied art, purely because there is more of reality in something devoted to the comforts of man than in that which is intended to conduce to its spirituality. Now, to begin with, as has come within the limits of my experience, there is, say a carved belt course about a contemplated building. The composition of the design to be employed is left to some draughtsman to work upon during an hour when he is not more usefully (?) employed. And this draughtsman is not necessarily the best man in the office. Usually he happens to be a student whose talent, however great, has not as yet been directed into the proper channels. Without regard to the character or the style of the building he proceeus with the first idea which happens to spring into his mind. The details are now complete. The next step is to invite some contractor of "cut stone" work to present an estimate. Of course, competition steps in and, as a rule, the work is "let" to the lowest bidder. He has taken the contract at the lowest figure at which it can be done, so he hies himself away to the presence of some monumental sculptor (?) or, still worse, to an ordinary "every day" stone cutter. Again, there is competition and, not infrequently, the stone-cutter is empowered to execute the carving to the best of his skill. His work is completed and the character of the design—if, by chance, the draughtsman has been lucky enough to give it character—is entirely lost through the lack of the proper artistic training of the artist (?). Thus one of the elements of harmony requisite to the unity of the perfect architectural composition has been debased and consequently the unity of the entire structure destroyed.

Of course we are aware that this force of circumstances is not altogether the work of the architect. Generally the favorite theme of the client, economy, enters largely into the subject. But, if we except even the latter step, the architect still remains guilty of the first impeachment, namely, that of placing the composition of the ornamental details in the care of an inferior workman. As he would not allow inexperience to prepare the drawings for trusses and other constructive work, so should he not allow the novice to experiment with the decorative.—*C. G. Robinstein, in Western Architect and Builder*.

INTERNATIONAL COMPETITION.

THE TRUSTEES, appointed by Mrs. Phebe A. Hearst, hereby invite the co-operation of the Architects of the world in the preparation of a permanent, general plan of the buildings and grounds which are to compose the University of California, in Berkeley, (near San Francisco), California.

Dated at San Francisco, California, December 3, 1897.

J. B. REINSTEIN,
JAMES H. BUDD,
WM. CAREY JONES,
Trustees of the Phebe Hearst Architectural Plan of the University of California.

I hereby guarantee the performance of all the conditions and covenants set forth in this Programme, to be performed by the Trustees of the Phebe Hearst Architectural Plan.

San Francisco, California, December 3, 1897.

PHEBE A. HEARST.

J. B. Reinstein, James H. Budd and Wm. Carey Jones, as Trustees appointed by Mrs. Phebe A. Hearst for the obtainment of an Architectural Plan of the buildings and grounds for the University of California, have deposited with the London, Paris and American Bank, Limited, at San Francisco, California, securities of the value of $50,000, as a fund to guarantee the performance by said Trustees of all their promises and covenants contained in the Programme for an International Competition for the obtainment of such Plan, which Programme is dated December 3rd, 1897. The said fund of $50,000 to be paid over and delivered only upon the order of said Trustees or a majority thereof, and their successors in interest.

December 3, 1897.

London, Paris and American Bank, Limited.
San Francisco, California.

MAPS, CASTS AND PHOTOGRAPHS.

Maps, photographs, casts, and necessary documents can be obtained from Mr. B. R. Maybeck, No. 7 Rue Honore Chevalier, Paris, France, or from the Trustees.

THE BEST FIREPROOF CONSTRUCTION FOR BUILDINGS OCCUPIED FOR MERCANTILE PURPOSES.

PAPER READ BY W. L. B. JENNEY BEFORE THE FIRE UNDERWRITERS' ASSOCIATION OF THE NORTHWEST.

THE SERIOUS loss in great stores during the past few years has created an intense interest among owners, underwriters and architects, as to the available methods for protection and their relative merits. This is the subject of my paper.

First we will consider the conditions that usually obtain. The great department stores are necessarily of large capacity—several stories, each floor of large area. The effect or the impression that the store makes upon customers is in proportion to the unobstructed area. This and convenience of business make subdivisions or cross walls undesirable in these retail stores, and notwithstanding the reduction in insurance rates, amounting to a considerable sum on the large amount of property, such walls are exceptional.

The contrary is the case in the wholesale stores where there is no attempt at display. The business itself is divided into departments with different clerks, so that the separation of the building by walls, is not at all objectionable. In the retail store the shelving for the display of goods is not allowed to exceed a reasonable height, because it would have the same effect as cross walls of dividing the store. In the retail store the goods are all out of the cases and piled loosely on wooden shelves. This, together with the large areas, makes the retail store rather more hazardous than the wholesale.

In the great fire of last May in Pittsburgh, a large fireproof store was subjected to very trying conditions, the entire stock burning on several floors at the same time and intensified by the great heat from a raging fire—the burning of a large wholesale grocery store across the street to windward. This fire presents the most practical lessons that exist of the behavior of a fireproof building under the most trying conditions. Fortunately this fire has been very carefully and exhaustively reported by able experts employed as appraisers. These reports have been published in full in the Insurance World of May 8th, June 1st, and July 1st. Fire records alone are conclusive and as these reports are the basis of my argument, we will, if you please, make some extracts therefrom, as I shall have occasion to refer to them repeatedly.

Referring to the map of the burned district, Fig. 1 the

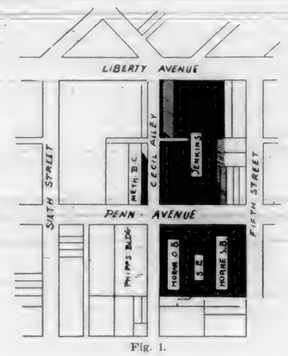

Fig. 1.

morning of May 3d, the Jenkins Building, a great wholesale grocery store filled with goods more or less combustible, some of them exceedingly so—such as oils, hams, bacon, sugars, etc.—that make a very hot fire when once thoroughly ignited—was found to be in flames. The building is reported to be what is known as "Mill Construction" without any subdivisions. When the fire was raging furiously the street wall on Penn avenue fell. The Horne store building across the street a little diagonally was of modern steel construction, each story carried independently on the columns. It was six stories above the sidewalk; the street fronts were some 60 per cent plate glass; the piers being simply steel columns fireproofed with masonry.

Instantly following the fall of the wall of the Jenkins building all the plate glass in the Horne store disappeared from the sash, and the stock was set on fire over the entire building and burned furiously. Across Penn avenue opposite the Jenkins building, was the Horne office building, four stories high, the two lower stories occupied as stores. Across Cecil alley from the Horne building was the new

Phipps building, eight stories high, of steel fireproof construction designed for an office building, recently completed, but at the time not occupied. Immediately across the alley from the Jenkins building was the Methodist Book concern, a building of modern construction but with partitions of wood studding covered with expanded steel lathing and plaster, which, wherever exposed to the heat, was badly damaged, the result of which shows that any woodwork in such a building is a mistake. On the roof of the Horne store stood a water tank weighing some 26 tons when filled. This tank was located directly opposite the elevator shaft where naturally it was particularly exposed to the heat. The supports gave way and the tank was precipitated through the building to the first floor, carrying with it the columns and beams which it came in contact with, causing the greater part of the injury to the building.

The engineer experts, Gustav Kaufman, consulting and contracting engineer, Emil Swensson, general superintendent Keystone Bridge Works, and F. L. Garlinghouse, chief structural engineer employed by the appraisers to assist them, all men of large experience and high standing in the profession, made a very careful and exceedingly valuable report, published in the Insurance World of July 1st, from which I shall quote.

According to the report "but a few moments after the fall of the wall of the Jenkins building, both the Horne office and store buildings became a mass of flames so fierce as to drive the firemen from Penn avenue and Fifth street to the roofs of the buildings surrounding the fire. The new Phipps office building was badly scorched and the Methodist Book building above the fourth floor was completed gutted of its contents." The two Horne buildings were reasonably well constructed and the fireproofing equal to the average. The engineers report that the general effect of the fire was the wreck of the eastern side of the Horne store building, caused principally by the falling of the water tank. After the fire they found a slight lateral movement had taken place in the Horne store building although not sufficient to cause any injury to the steel; still they attribute to this movement the scaling off of many of the lower webs of the floor arches and the dropping out of much of the fireproofing on the underside of the beams and girders. They believe, however, this latter is due at least in part to doubtful methods of attachment. The columns in the building were all carefully examined with a transit instrument and by plumme- observations and close visual scrutiny. The greatest det flection found at any point in a whole tier did not exceed 2 inches. The girder sand beams were also subjected to the closest scrutiny and a careful record made of each and every one. Every rivet in the building that was exposed was tapped and not one loose rivet was found. All connections were also examined and were all found in good condition as far as could be determined. Material that had been subjected apparently to the greatest heat was tested by cutting out test pieces as close to the bend as practicable. These tests were made exactly as is made for the new material—the elastic limit, breaking test, extension, reduction in area, best fireproof construction for buildings . 2 the nature of the fracture, etc. In the opinion of the board, the fire had not damaged the steel, that it had acted rather like an annealing furnace and that the material was rather improved than injured. The slight sinuosity in the various tiers of columns the engineer board does not attribute to the action of the fire alone, as possibly a small amount of it was caused by the setting, and existed originally.

This board makes it comments on the lessons taught by the fire as follows:

"First, in buildings of about this height the distortion of the steel frame work due to the heat of the fire, cannot in any instance be sufficient to work any serious damage nor is it probable that at any time would connection rivets be sheared off. This conclusion is arrived at for the reason

W. L. B. Jenny, Architect.

that there is no probability that any future fire will be fiercer than the one at issue.

"Second, the method of fastening fireproofing to the underside of beams with sheet iron strips should be discarded.

"Third, it cannot be too often reiterated that open front buildings like this should be protected from external fires by metal shutters."

In this I fully concur. Rolling steel shutters such as those in use in the Marshall Field & Co's Wholesale store on Adams street in this city, can be readily applied to the front of a building without detriment to its architectural effect. They are easily worked. If closed every night, as in that store, they are always in order. On the rear and alley elevations the ordinary standard shutters are all sufficient. In the Pittsburgh fire wooden shutters covered with tin did good service and assisted materially in stopping the fire. The engineers also further advise "that all shafts should be provided with metal doors that can be readily closed from all floors." This is attended with serious difficulties. In many of the large department stores there is a central light shaft of considerable dimension. No satisfactory arrangement has as yet been put on the market for the closing of these large openings at each story. Even in the smaller openings of staircases, the doorways in use are scarcely adapted to retail stores. They can, however, be shut off by vertica]

The inventor makes the following claims of merit :— The Heater weighs about 150 pounds and its corrugations are made to a depth of three inches, and this combined furnishes a radiating heat equal to four times of any straight back fire-place, These corrugations also cause a draft at the back of the fire where other fire-places will not burn, and increases and distributes a uniform draft to all parts of the fire, producing perfect and gradual combustion. This Heater burns hard and soft coal to a fine ash, and equal to any base-burner, stove or furnace, and will furnish fully twice the heat of any stove in the market. It is the only fire-place Heater that will start and burn hard coal and in fact any kind of fue. without a blower, the housekeeper is thus relieved of having this article about the rooms.

By the use of the Lytle Heater perfect and slow combustion of fuel is secured and 95 per cent of the heat is utilized-

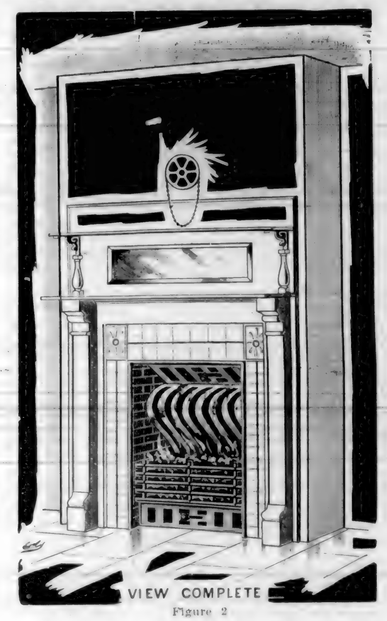

Figure 2

It works simple, and keeps fire over night equal to any stove or furnace.

When gas is used for fuel the flames roll up through the corrugations of the Heater and will heat that body red hot if desired, which causes a flow of hot air through the register that cannot be equaled by any other Gas Heater.

The discharge of hot air into the rooms with the Register located within about three feet from the ceiling forces all the cold and impure air to the floor and the suction at the open fire-place draws the same to the chimney flue and there out, thus taking out of the rooms all exhausted atmosphere, and constantly replenishing with pure heated air without exposure or drafts, and causing perfect ventilation. This feature recommends our Heaters for the nurserooms and hospitals as being unsurpassed for heating and ventilating.

This Heater is economical as well as sanitary in its results. It secures warm floors and equalizes the temperature from floors to ceiling, perfect ventilation is secured.

rolling shutters between stories so that the light shaft be comes a chimney for the escape of the smoke.

"Fourth, the most important lesson taught by this fire was the lack of strength displayed by the fire-clay fireproofing. The building was permitted to move in any direction without any material restriction by the firepoofing. The floor arches showed by the scaling off of the lower webs that they were unable to offer any sufficient force to counteract the tendency to lateral motion.

Fifth, the column protection although composed of the very best obtainable kind of fire clay tile was also not of sufficient strength.

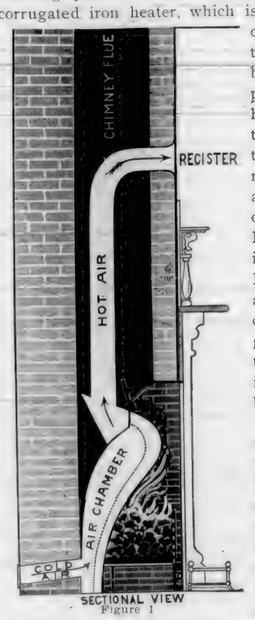
In our opinion it would have been necessary to dismantle the whole steel frame work had this structure been 14 or 15 stories high. The leaning at that height at the same proportion as developed would have entailed the necessity of taking the whole structure down.

Owing to the fact that steel columns or girders or beams after being subjected to a long continued fire will assume the same temperature as fireproofing, and owing to the fact furthermore, that the rate of expansion of the steel is much greater than that of the fire clay tile, destructive movements are permitted which, as shown in this experience, will result in considerable damage and which damage will increase in direct proportion to the height of the building.

To be continued.

THE LYTLE FIRE PLACE HEATER.

FIGURE one shows a sectional view of a Lytle Heater in the fire-place. The cold air taken from outside of the building passes through a pipe into the base of a hollow corrugated iron heater, which is placed upright with its corrugations in the direction of the draft and at the back and crown of the fire-place where the greatest heat is found, which causes the supply of pure air in the air chamber to heat and rise rapidly into the hot air pipe, connecting the top of the Heater and the Register, and thence pass into the rooms through the Register. Figure 2 shows a front view of the Heater complete with its corrugated front at the back of the fire-place, and the position of the Register in the breast of the chimney.



SECTIONAL VIEW
Figure 1

With the adjustment of the top and lower dampers the fire can be regulated to burn slowly and work, if desired, the entire season without rebuilding, the same as any base burner, stove or furnace. This Heater can be put into any fire-place and guaranteed to work in any chimney regardless of stove or furnace working in the same flue.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

See a full size working model at our store.

411 MISSION ST., Bet. 1st and Fremont, SAN FRANCISCO, CAL.

BEST FOR WARM CLIMATES

Cannot Crack or Peel as Pain Does.

Being *in* the wood, and not wholly on the surface, like paint.

CABOT'S CREOSOTE SHINGLE STAINS

wear better and longer in warm el mates than paint, which cracks and peels off under the hot suns. They are he only exterior colorings that do not turn black, and the only treatment that will prevent the blackening of Redwood. No other Stains can contain Creosote, "the best wood preservative known," our patent giving us the sole right to make, sell or advertise Creosote Stains.

The *Siding* of the Kip Mission, above, is Creosote Stained.

Samples and prices on application to

FACTS ABOUT PAINTS.

PHŒNIX
PURE
PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

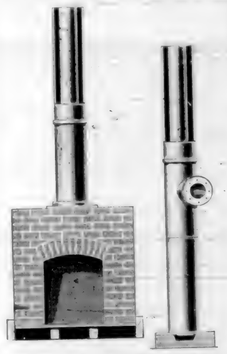
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAUSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price. $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

Webster near Union. Cottage; owner, William A. Matheson; architect, R. B. White; contractor, Petterson & Person; signed, March 7; filed, March 9; cost $1729.

Webster near O'Farrell. Alterations and additions; owner, Mrs. Carlotta Gaudin; architect, C. M. Rousseau; contractor, Geo. C. Nall; signed March 2; filed, March 4; cost $4800.

Taylor and Washington. To build; owner, Mrs. W. Loaiza; architects, Pissis & Moore; contractors, Bignami & Masow; signed, March 14; filed, March 15; cost $11,390.

Turk near Buchanan. Alterations and additions; owner, Gabriel A. Abraham; architect, A. J. Barnett; contractor, W. Paterson; signed, March 16; filed, March 16; cost $2100.

BUILDING NEWS.

OAKLAND

Thirty-Sixth near Grove. To build; owner, Arthur Beckett; contractor, John P. Beckett; signed, March 7; filed, March 17; cost $2800.

Adeline near 16th A. To build; owner, Meyer Levy; architect, C. A. Doss; contractors, Schley & Doss; signed, March 2; filed, March 4; cost $3000.

Park Ave. and Frederick. Cottage; owner, Mrs. E. A. Davis; architect, Reeves Davis; contractor, Ben. O. Johnson; signed, Feb. 10; filed, Feb. 19; cost $1675.

Adams Point, lot 13, block 5. To build; owner, F. M. Umphred; architect, D. F. Oliver, contractor, S. A. and H. W. Norman; signed, March 7; filed, March 8; cost $3687.50.

Mr. Jacob Levi, of San Francisco, who last week purchased the Wilcox Block at 9th and Broadway, with the two-story frame building on Ninth street, the lot being 100x150, intends to remodel the block into office building.

The Builders' Exchange have passed out of existance—discouraged and shut up shop. Lack of interest, owing principally to the great depression of the building trade, together with a tight money market and consequent failure to pay dues—principal causes.

EAST OAKLAND

Hanover near Newton. To build; owner, Thomas Cowell; architect, W. Budson; contractors, L. E. Compbell, R. H. Fallmer; signed, Feb. 11; filed, Feb. 24; cost $1278.

Jackson near Lake. Plumbing, etc; owner, E. G. Lukins; architect, Clinton Day; contractors, W. S. Snook & Son; signed, Feb. 26; filed, March 1; cost $1795.

ALAMEDA

Bellevue tract, lot 11, block D. To build; owner, C. L. Robinson; architect, Geo. A. Bordwell; contractor, signed, Feb. 17; filed, Feb. 21; cost $2146.

Clinton Ave. and Walnut. Two-story frame; owner, A. B. Pau, Jr.; contractor, E. D. Judd & Co; cost $4300.

San Antonio Ave. near Paru. Two-story frame; owner, Geo. T. and Sophie L. Wright; contractor, A. W. Pattiani & Co; cost $4798.

Benton near Santa Clara. To build; owner, G. A. Rosenberg; architect, M. G. Bugbee; contractor, Theo. Victors; cost $1080.

St. Charles near Louise. To build; owner, Geo. F. Hever; contractor, F. Bammann; cost $1850.

St. Charles near San Antonia. Carpentry work, etc; owner, F. W. Voogt; architect, B. E. Remmel; contractor, D. S. Brehaut; cost $3500.

The Bray school district have cleared away the obstructions that were blocking the way to the issuing of bonds for the new $13,000 school house. Everything now looks favorable for building operations to begin in the near future.

SAN LEANDRO

The County Supervisors have decided to build a concrete arched bridge at San Lorenzo creek, opposite the Meek place.

The plans of architect Smith for a new laundry building at the County Hospital have been accepted and operations will be begun at once.

Cotton Bros.' plans for the new Webster street bridge have been accepten by the supervisor as approved by the Navy Department.

BUILDING NEWS.

BERKELEY

The highlands, block 1, lots 7 to 10. To build; owner H. W. Hawley; architect, F. D. Voorhees; contractor, Siedel & Mohr; cost $3284.

SAUSALITO

Block 5, lots 1 to 3. To build three two-story frames; owner, Charlotte Wilson; architect, Albert Sutton; contractor, Mallory & Swenson; signed, Feb. 17; filed, Feb. 23; cost $4951.

SANTA ROSA

Judge Dougherty and Mr. Shea will erect in the near future a handsome business block on the lots purchased by them last week of Mrs. S. A. Loucks.

STOCKTON

Downing & Hemme, architects are receiving bids at 3 p. m., to-day for a two-story frame residence to cost $3000 for Daniel Harris to be erected on Vine near El Dorado streets.

The following buildings have just been completed and accepted by Geo. Rushforth, architect: The six room brick school building cost $11,000 for the trustees of the South School District, and the new hotel and passenger depot at Jamestown, containing 64 rooms and costing $25,000 for the Jamestown Improvement Co.

The handsome store building to be occupied by the owner D. S. Rosenbaum of this city, is just completed at a cost of $5000; W. W. Oates was the architect.

FRESNO

Chas. Beasley & Son, architect of Stockton has just completed plans for a business store to be erected in Fresno for W. Parker Lyon & Co; bids for brick work, concrete and sidewalk lights are now called for, the front will be constructed entirely of metal, with aluminum sash bars and plate glass and the bids for this and other work will be called for in a few days.

AUBURN

H. C. Herrill, Chas. Keena and Anderson Brothers will soon build cottages.

REDDING

R. S. Jewell is soon to erect another fine modern cottage of six room, brick basement for laundry, wood, etc.

Sacramento parties are soon to commence the erection of a large livery stable and office building on Butte street. There are to be six suites of modern offices above with broad stairs looking up from the street.

F. P. Primm, attorney, will erect opposite the Temple Hotel an office building, stores on first floor of modern methods of construction.

The Episcopal Society are now securing funds to build a new church and to raise $10,000.

Dr. Kohm will erect a two-story brick, store and office and home above.

Hon. E. Frisby, banker, is having ten fine cottage constructed to relieve the demand for houses that is on the constant increase.

Masonic Building Assn. will make many improvements in their building.

GAZELL—Denney Bar Parker Co, will build a large brick store and ware house two story early this Spring.

KESWICK—There will be two brick buildings go up early this Spring; this town has built over 200 houses and 50 business buildings in the past year.

Architects Austin & Skilling have prepared plans, for Harvey Cox, of a two-story nine room, residence; white cedar inside finish, plumbing, gas and electric ghting; to be erected on Thirtieth near Hoover.

BUILDING NEWS.

Architects Morgan and Walls are preparing plans for L. A. Thompson, of a twelve room two-story residence, to be built at Kensington Road and Douglass street; it will be complete with all modern conveniences and will have maple floors, plate glass windows, hardwood inside finish, gas and electric lighting.

Plans are being prepared for the Los Angeles School of Osteophotny, of a large two-story frame building, which will be used as a school for the instruction of pupils, to be built on Figueroa street.

Architect Krause and Jenkins are preparing plans

BUILDING NEWS.

for Easton, Eldridge and Co. of two additional cottages, to be built in the Menlo Park Tract.

Sixteen sets of plans were submittrd to the trustees of the First M. E. church in response to their call to architects. The first meeting for the purpose of examining them was held on Saturday evening. Each architect is allowed thirty minutes to explain the best points of his particular set; as it will require a number of meetings to examine the large numbe presented, it will be at least two weeks before a decisi ion can be arrived.

VOLUME XIX. MARCH 20th, 1898. NUMBER 3.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

SINCE our last issue Mr. E. H. Burrell has succeeded to the interests of Mr. Tom M. Grant in THE CALIFORNIA ARCHITECT AND BUILDING NEWS. Mr. Burrell now being the sole lessee and publisher while Mr. Grant is retained by him as the Editor. All bills against the paper will be paid by Mr. Burrell, and all moneys due and coming due are to be paid to him.

THE GENERAL tendency of business for some years past has been, for a smaller number of individuals as principals, to do a larger business at a smaller profit. But in the business of contracting to build, the tendency has been, on the contrary for a larger number of individuals to do a smaller business, at no profit at all, and often at a loss. This does not often fall upon the contractor, because a large majority have nothing to lose. These conditions have naturally reduced the number of responsible and experienced contractors; many of whom have abandoned the business voluntarily, while others have been obliged to do so, after sacrificing their legitimate accumulations in the throat, cut purse scramble we call competition.

It is claimed by some sufferers that the prevailing conditions have been the result of a grasping disposition on the part of owners; others again insist that architects are to blame in encouraging incompetent, irresponsible bidders. But it must be remembered that the system, if we can call an anarchistic state of things a system, has encouraged incompetent, irresponsible people who have failed at other employments, to adopt the calling of contracting, or the profession of architecture; and it is not wonderful if these disturbers of the peace and prosperity of a community, should combine to get a living at other peoples' expense.

We believe that no improvement can be hoped for as long as the "Lien Law" is in force. The law relieves every body connected with a building operation of responsibility, though it is ostensibly intended to fix responsibility and protect innocent parties. In practical operation it enables any impecunious person to get credit and bonds, in order that he may have the handling of the funds to be distributed, often pro rata; in consequence of the impossibility of doing the work at the contract price, or because in the handling, too large a percentage has adhered to his sticky fingers. Sound business principles are always in the long run, stronger than any statute that conflicts with them, and that

attempts to prevent their action. This is what might be expected, because business principles are the result of the experience of the world for ages, and have become a natural force that can be counted on, like the law of gravity; and any attempt to ignore it or defeat it, brings confusion to the man or class, who make the attempt. It has been believed that the Lien Law was a necessary protection, first to the journeyman mechanic against the misfortunes or dishonesty of his employer; the contractor; then to the sub-contractor against the same. The business community has, however, discounted the practical working of this elaborate machinery to entrap an unwary owner into paying for twice as much as he receives. A counter machine of bonds, and retention of contract money, together with time limits, and other technicalities, was soon set up; and while the expenses and uncertainties of building for all concerned, have been increased by this legislation, and counter legislation, the inevitable net result has been to increase unscrupulous competition; or rather to turn the business into a gambling scheme, as devoid of business principle as a bluff in a game of cards.

The fact is that the Lien Law is class legislation, and as such has been pronounced unconstitutional by the Supreme Courts of more than one State. The Supreme Court of the State of Ohio used this language in a decision in 1897:—"No court can see that it is for the common public welfare that the liberty of contract should be taken away from the owner of a building to enable the seller of materials to collect their value from a man who never purchased them, and who has already fully paid the one with whom he contracted for all that he received."

It will be seen that without a lien law, business would be transacted on the usual basis. Bonds would not be expected, because owners would take only the usual business risks in employing contractors—and these risks would be mutual. Hence only responsible parties could engage on either side, and remuneration would be adjusted as real compensation.

THE United States Circuit Court of Appeals for New York, has held that the burden of proof is on the fire insurance company to prove as a defense that the insured building fell before the fire. It may be doubted if this decision is in the interest of good honest building. The underwriters have a clause in their policies providing that insurance shall immediately cease in the event of a fall of a building, except a fall caused by fire.

FOREIGN fire offices is this country have earned a good reputation for careful underwriting, fair settlement of losses, and prompt payments. They pay their share of taxes and bring capital to the country. We have examined the figures of litigated claims, and find that the percentage resisted by foreign companies is the same low average (less than two per cent) as that of the American companies. In some quarters, not altogether creditable, there are signs of a disposition to make war on the foreign companies, by levying a discriminating tax on their receipts. This narrow, inhospitable spirit is not shared by the respectable American companies' managers. Our readers may confidently accept the indemnity of foreign companies, with the assurance that the security is first-class, that the capital invested here is needed and beneficial, and that the foreign underwriters supply a demand which our home companies and home capitalists are unable to fully supply. It is not true that the foreign underwriters are supplanting American underwriters. The percentage of premiums paid the former remains substantially the same year after year. It is about thirty. The amount of money sent home is surprisingly small. The profits, which average only three per cent of the premiums, are nearly all invested in this country. When a Commissioner of Insurance descends to abuse of foreign insurance companies, which furnish such safe indemnity, his misrepresentations and alleged arguments may be dismissed as the screed of a demagogue who is open to the conviction of the "hush money" argument.

THE BUILDING LAW passed over a year ago in St. Louis has gone into operation, and in future buildings in that City will be limited to one hundred and fifty feet the same as in Chicago.

There has been much discussion in many cities in recent years concerning this subject of limiting the height of buildings. In Chicago this resulted in limiting the height, just as it did in San Francisco, and now the New York Legislature has had a bill before it limiting the height in New York City. It has been whispered that some of the extremely tall buildings in New York and Chicago have shown signs of insecurity that have caused the architects and owners a degree of uneasiness which requires a constant and very careful watch to be kept upon every point. Nor is the fact to be wondered at, when it is considered that some of these buildings are erected on a base so small as practically to assume the form of towers, rather than of buildings. The St. Paul building in New York for instance is 300 feet high, with a frontage of 39 feet, the proportion of base to height being thus nearly one to ten, so that the building has about the proportions of an ordinary lead pencil. Here in San Francisco there is but one building that approaches like proportions, and while that towers up to a height of 310 feet it has a base of 71x75 feet, the proportion of base to height being one to a trifle over four. The St. Paul building is an exaggrated case, but there are a large number of buildings in New York and Chicago between 250 and 300 feet in height which are built on lots of less than 100 feet front.

WE PRINT herewith a view of the elevation of the New Ferry Depot Building, of which Mr. E. R. Swain is the Supervising Architect and the State of California the owner, by the grace of its board of Harbor Commissioners.

A morning paper would have us believe, and all of its many thousands of readers believe, that in the building of this ferry depot every official of the State, save *one*, and every contractor, save *one*, who has had anything to do with the construction, was a bribe taker or a bribe giver, all equally guilty in a gigantic criminal conspiracy to defraud the State out of thousands of dollars.

Many of these contractors, all in fact, with whom we have

a personal acquaintance, have lived in this City for many years, have engaged actively in their several lines of contracting, raised respectable families, accumulated some property, paid their just debts and have been considered, by their fellow men as good and law abiding citizens.

With the business standing or reputations of the State officials who are in anyway responsible to the State for their acts in connection with these alleged frauds, it is not within the province of this journal to deal, probably they are fully up to the average successful politician as he exists in this State to-day, no better and no worse. They at least may be trusted to look after their own affairs, first, last and all the time, and in doing this it is hardly to be credited that they would undertake the carrying out of all these alleged frauds in such an open and bare faced manner as the morning paper would have us believe.

Mr. E. R. Swain, the Supervising Architect of the depot

building, has practiced his profession with unvarying success for something like thirty years. His position for several days, while under fire, must have been a most trying one, but he proved himself equal to the occasion, and after breaking his seal of silence and coming out into the open, assumed responsibilty for all the changes that have been made. He says:

"As the architect of the board, it is my duty to see that the contractors do their work according to the plans and specifications under which their contracts were secured. It is also my duty to attend to all details in consideration with any changes in the plans or specifications that may be contemplated or agreed upon. In doing this I have endeavored to use my best judgment and to have in view the best interests of the State.

"Every change that has been made in the original plans and specifications for the ferry depot building has been at my suggestion or has received my approval. Allowances made to contractors have been made upon my estimates or have received my approval. In other words, all of the work upon the building has been under my supervision. If the Board of Harbor Commissioners, or through it the State, has been victimized by contractors, then I must be either a fool or a knave."

This is direct, straightforward and to the point, and surely is not the utterance of a guilty man nor of that of a fool. On the contrary it has the true ring about it, and must, most assuredly, be given more credence than can be given to charges of corruption and fraud, based upon information furnished by disgruntled contractors, "discharged-for-cause" employees, politicians out of a job, and politicians of opposite political faith who believe in and are always looking for the addition-division-and-silence-end of every proposition in which the State is the paymaster.

As no stream has ever been known to rise above its source how are we to believe that the information furnished the *New Call* can be any more trustworthy than its source. While that paper readily enough gives out the name of its so-called marble expert it masks behind "an eminent authority" the master spirit of all the technical knowledge that has appeared in its columns, illustrations included. This clearly would not be the case unless for cause. The name of a reputable architect given to the community as sponsor for the correctness of the *New Call's* charges would make the charges of fraud and corruption assume another color entirely, and would have carried weight and conviction wherever that paper was read. But as the case stands now the contrary effect is the result, and motives are more looked for and discussed than the charges themselves. There can be but one conclusion regarding this "eminent authority" and the *New Call's* reasons for giving out these technical reports in the anonymous form they have always assumed. It is more than probable that this "eminent authority" would not be entrusted by the proprietor of that paper to build an out-house, that he never has built to that extent for him nor for any member of the family, and what is more, doubtless, never will.

We have excepted in the second paragraph of this article one contractor and one official as being beyond the pale of the *New Call's* charges of fraud. If it is to be presumed that they alone are innocent of all the number that are connected either as officials or contractors, with the ferry depot building, the interesting thing is to know how they escaped their share of the hot pitch.

The excepted official being no other than Mr. Howard C. Holmes, chief engineer to the Board of Harbor Commissioners, whose duty it has been since the inception of the project to guard the interests of the State. Mr. Holmes is not only a very capable engineer, but is a man whose integrity and honesty has never been impugned by the press of this

City, which in view of recent events, and his long services in an official capacity to the State is a remarkable record and one of which he can well be proud.

Yet all the changes of note that have been made at the ferry depot building, have been submitted and passed upon by Mr. Holmes, and upon his approval final action taken by the commissioners and the changes ordered made. For the changes in the floor construction which the *New Call* denounced as a job and a fraud one day and then took it all back, the next, Mr. Holmes assumes his full share of the responsibility. And still the *New Call* has only good words for the Chief Engineer, (who has been "the man in the door" for the commissioners) notwithstanding the fact that these so called fraudulent charges were passed upon and approved by him.

Taking either horn of the dilemma the *New Call* gets the worst of the argument for it is not to be admitted for a moment, that an honest, keen and shrewd official like Mr. Holmes could pass upon and approve these changes of record without knowing their true character, nor could the object for which such changes were made miss being brought home to him.

The one lone contracting firm, who, as mentioned in the second paragraph, has so far escaped the *New Call's* wrath and hot pitch, were the contractors for the foundation walls and included with them, of course, is the side partners who furnished the cement.

So, summing up the whole case, we find that somewhere between February 1 and March 12 the president of the Harbor Commission; in his capacity as Editor of the *Stockton Evening Mail* bore down in its columns in his usual suave, ax-handle manner upon the anomalous political position occupied by the young inexperienced managing Editor of the *New Call*.

The y. i. m. editor to get even and make the Chesterfield of the Harbor Commissioners and rural Editor eat his words or feel the mighty power of a truly Metropolitan Daily, in looking about for the means to an end, which would mean the political end of the rural Editor for all time, pounced upon the new ferry depot building as the most available mark.

The *New Call's* reserve force, the regular force and the irregular force were then equipped with one sided instructions and turned loose upon an unsuspecting community, since which time it has been told day after day, in double column display and in editorial array that the contractors whose records are printed herewith, are robbers, jobbers and conspirators for crooked work.

Here, for instance, is a fair sample of the opening sentence that starts the ball rolling every morning:

"From amid the mass of robbery, jobbery and crooked work that has marked every stage in the progress of the construction of the new ferry depot building, etc., etc., *ad libitum, ad nauseam.*"

All this and more, daily, of the same category, notwithstanding the fact that many of these contractors had acquired honorable distinction in their several walks of life before the y. i. m. editor was born.

But of what avail is your good name, of what avail is mine, of what avail is anything in this work-a-day-world of ours, until the mighty pent up rath of this y. i. m. editor has been appeased, the insult biotted out, and the political death of that rural writing and publishing Harbor Commissioner, an accomplished fact.

By all means let us have an investigation, but let it be thorough and complete. If the Grand Jury is the proper legal authority, then let that body take up the matter, by selecting a commission composed of reputable architects, who can act openly and above board, and whose report when made public will convince the people of this State that the truth and nothing but the truth, has been told in their report. As to the various sums of money that have been saved to the State by the numerous changes and the disposition thereof, let that also be the subject of exhaustive investigation by the Grand Jury, and no matter where the lightning strikes, "let no guilty man escape," say we.

THE CONTRACTORS.

Western Expanded Metal Co., D. E. Garrison, Jr., Pres.: C. F. Runyon, Vice Pres.; Gen. S. W. Backus, Sec'y. and N. L. Bell, Manager.

The Pacific Bridge Company—C. McCarthy, Sec'y. Established 20 years and have never had a law suit of any kind.

W. W. Montague & Co. for forty years the leading house in their line on the Coast—C. Adolph Low, Geo. A. Low and the heirs of the late Admiral Baldwin are the partners.

Bateman Bros., fifteen years in the business of contracting.

Ed. B. Hinds—contractor for rolling gates and shutters. Established 12 years. His work at the Claus Spreckels Building is his best reference.

Wm. Cronan—Established and doing a successful business for twenty yeats.

Duffy Bros., established 20 years. The class of work they do can be seen at the Mills, Claus Spreckels, Mutual Life, Emma Spreckels and Supreme Court buildings.

OBITUARY.

WE REGRET to have to record the death of Mr. Augustus Laver, senior member of the firm of Laver & Mullany. He was a native of London England, and was over sixty-three years old when his useful career was ended. He was a F. R. I. B. A., a member of the A. I. A. and of the Masonic fraternity. As an architect he had an international reputation being associate architect of the Parliament Buildings at Ottawa, Canada and the New York State Capital at Albany. On the occasion of the selection of his plans for the City Hall of San Francisco, he settled in California and has been identified with the best and most solid architecture of that city ever since. His works here are too well known to need enumeration but we may mention—the residences of the Flood family, both in San Francisco and Menlo Park—the Flood and Montague buildings on Market street and the O'Brien Mausoleum.

Of his character the best enconium that can be made is that he was in every respect *a gentlemen*, his manner was courteous and polite to all and the community has lost in him a good specimen of the upright citizen, the Architects a worthy exponent of the dignity of their profession. More than this nought need be said.

HIGH SCHOOL COMPETITION, FULLERTON, CAL.

SATURDAY, April 9th at 1:30 P. M., the Fullerton High School Board will consider plans and specifications for a High School Building. For particulars address,

WILLIAM STARTRICK,
Clerk of Board, Fullerton, Cal.

BURNT WOOD IN DECORATION.

HE WHO has within him the divine fire of genius must perforce give expression to noble ideals: the medium employed, and the hand that wields it, are but servants of his inspired mind. In other words, a good draftsman can draw with anything. The decorations which have best withstood the ravages of time, and are the most chaste and refined, have been produced with the simplest means possible—chisel, mallet, and marble; chisel and wood; modeling-tool, clay, and fire: sheet-metal and hammer. What could be more direct and simple than red-hot iron and wood?

DECORATIVE PANEL FOR CHEVAL MANTEL.

Many years ago the manual labor of the artist in color was reduced to a minimum: he no longer grinds his colors, or makes his canvas and brushes. But up to the present day the artist in burnt wood has toiled on with his rude forge and burning-irons, with the devotion of an old-time alchemist. Singularly enough, relief from the discomforts of this crude mode of work has at last come through the avenue which brings relief from all physical ailments—that of medicine. The thermocautery, a surgical instrument invented for cauterizing, has been adapted to the use of the artist, so that he can work with comparative freedom.

The wood-carvings and wrought-metal work of the middle ages attract the lover of the picturesque by certain irregularities of line and angularities of curve and plane, which do no injury to the whole, yet give it a character not found in the work of the rounded, sandpapered school of to-day. The tools of these masters were often crude, and many of these accidental accents were doubtless due to this fact. Yet these men expressed grand ideals, and their work as it stands to-day has an individuality which is largely due to this very picturesqueness. There are comparatively few workers in wood to-day who appreciate this quality, and only recently has really artistic wood-carving been done by American carvers. One of our most eminent architects, in speaking of the desire of his wood-carvers to destroy all character by the sandpapering process, says that it is necessary to stand over these men and to take to take their work from them while they still consider it unfinished.

Burnt-wood decoration must be something more than a simple scorching or tinting of the wood: the same effect can be more easily produced with bitumen or Vandyke brown. Its value as a means of decoration lies in the wonderful character of its intaglio line-work and flat tones, and in the picturesque inequality of surface which the more or less vigorous burning produces. He who best knows the value of a line can best practice this art; but he who seeks to create modeled realisms can only degrade it. A rigid devotion to accentuated intaglio line work and to the laws of flat decoration must of necessity result in original effects unlike those produced by other mediums.

As of old the master wood-carvers and violin-makers hoarded flawless, dry wood, so must the wood-burner of to-day keep a vigilant eye upon the lumber-yards, and lay in a stock of flawless, dry wood. His material cannot be too well seasoned. It must be white, free from gum, and soft: white because contrasts are wanted, and free from resin that it may not turn black with age. As it is the fiber of the wood which is blackened or carbonized, not the resin, it is obvious that the freer the wood is from gummy substances the better. The most satisfactory fire-etching has been done on panels of French poplar, which is soft, white, close-grained, and free from gum. The common white wood or yellow poplar of America yields readily to treatment with the hot iron, and can be successfully used in conjunction with harder, rarer woods, as beneath the magic touch of the burning tool it becomes rich and solid. The harder woods are more difficult to work, but, by combining the natural grain of woods like maple or oak with the rich burnt tones, beautiful results may be obtained.

I know of a hall which is paneled from floor to ceiling with golden-hued Mexican mahogany upon which has been successfully burned a frieze of delicate Renaissance traceries. On the other hand, I known of a low-toned dining-room paneled in antique black oak, with a deeply burned frieze, add containing in the massive chimneypiece a historical decorative portrait, and in the four walls other similar portraits, all in burnt wood.

PANEL EXECUTED IN BURNT WOOD WORK.

Every architect is willing to acknowledge that the utmost circumspection is necessary in applying any foreign material to architectural spaces. A glaring piece of mural painting, mosaic, or stained glass may destroy the artistic value of an interior, however purely and chastly conceived. It is obvious, therefore, that the very simplicity of the art of wood-burning, the unobtrusive quality of its color, and the utter impossibility of color discord, render it a safe and valuable means of interior decoration. Virtually it is closely allied to low-

relief ornament in wood, stone, leather, or metal, and is adaptable where these forms of decoration are used. Furthermore, its color-quality admits of its application in lieu of mural painting, tapestry, embossed leather, and tiles.

The commercial spirit of the age asks for decoration in large quantities, but it must be supplied cheaply; consequently the lover of truth and artistic originality is disgusted and disheartened at seeing the public accept and approve of mechanically produced decorations which are but base mockeries of nobler realities. The fire-etcher, after years of hard study in the futherance of his art, awoke one morning to find that a clever Teuton had invented a machine with engraved metal cylinders, heated to a certain degree, which reeled off decorative burnt-wood panels *ad nauseam*. It would be useless to compare or contrast this class of burnt-wood work with that of the artist. We can more easily consign it to its proper category—that of the branded shovel-handle and cigar-box cover.

It would be impossible to state positively when this art was first practiced. Burnt panels have been found in various parts of Europe, set into ancient furniture, chimney-pieces, and wainscoting. In the museums of Europe there are marriage-chests, coffers, and panels, dating from the fifteenth century or thereabouts, upon which a species of low-relief woodwork, not unlike the so-called "fret-saw" work of to-day, has been applied or chiseled out, the flat surface being richly ornamented with fine traceries unmistakably burned with heated points. Some years ago a New York artist, while wandering through the sea-shore villages of Whalés, found in a peasant's hut a rare panel of burnt-wood work of the Italian Renaissance (about the fifteenth century). The fisherman had found it on the beach, where it had drifted from some wreck. In the sacristy of the little octagonal church of Sant' Ercolano at Perugia are some ancient chests which were quaintly decorated with hot irons some four hundred years ago.

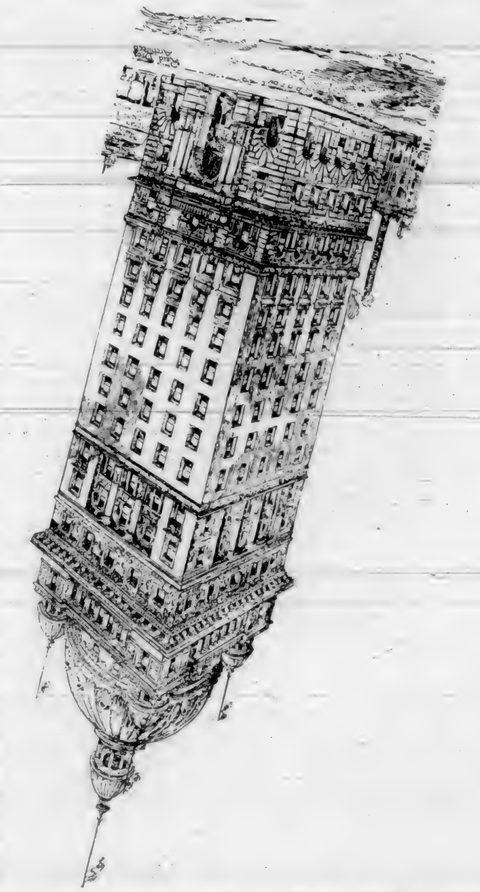
We are all familiar with the Japanese decoration of bamboo with the blowpipe, and any tourist to Switzerland or Germany can recall the rude scorching or tinting of the little carved souvenirs sold in the booths. These latter forms cannot, of course, be classed as manifestations of the art in question.

The art first made its appearance in this country nearly fifty years ago, when Ball Hughes, the English sculptor, residing in Dorchester, Massachusetts, became well known as a burner of "poker pictures." As copies of old English and Italian masters, they possessed merit, being executed with marvelous deftness. They were not decorative, nor were they intended to be such. Only recently has this medium been used in decoration, which is its only legitimate field.

Mr. H. C. Ives, art director of the Columbian Exposition, in his visits to all the capitals of Europe found but one interior completely decorated with burt wood. It was the reception-room of the Stockholm Technological School of Art, which school says Mr. Ives, is one of the best in the world. The apartment—a reception-room adjoining the director's office—was finished in every part by students. The mass of the woodwork was dark; the panels of doors, wainscot, and ceiling were all of satinwood, into which had been burned Renaissance designs. The decorations of the room, comprising stained glass, embossed leather, porcelain, etc., were all the work of students—"a rare pleasure," says Mr. Ives, "to see the true idea of art education thus practically carried out in the adornment of the school edifice itself."

The art of wood-burning may be easily abused. The ignorant may debase it by failing to recognize its proper sphere, but it will become an important factor in the furtherance of pure decoration so long as it is employed by the artist alone; for surely only the artist can give it that seriousness and strength without which it will be merely a passing fad.

J. William Fosdick.



THE *New Call* in its efforts to out do all the "yellow journal" sensations, has got itself turned completely over, and it looks to the "man up a tree" as if the task of righting itself would be found a hopeless one. A leak can sink the largest ship that sails the seas.

VOL. XIX No 3 MARCH 1898

ILLUSTRATIONS.

The management of this journal desires to extend a cordia invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

A PERSPECTIVE view is shown this month, in the double page engraving, of the new home now building for the Wells, Fargo & Co. Express, and of which Messrs. Percy & Hamilton are the architects.

A history of this Company's career would really be a history of the progress and development of the middle far Western States, the founding of the Company dating back to the Spring of 1852. Anticipating the regular mail service across the Continent the Company, in April 1860, established the famous Pony Express between St. Joseph, Mo., and Sacramento, Cal., making weekly trips and carrying letters only.

Since the beginning of its career Wells, Fargo & Company has gone on uninterruptedly, maintaining itself successfully, until to-day it literally spans the American Continent "From Ocean to Ocean," and reaches across the seas. It now operates on 27,472 miles of railroads, 2,343 miles of staging, 6,346 miler of ocean steamers and inland navigation; a grand total of 36,171. From 78 offices in 1857, it has increased to 2,829 and gives employment to 6,000 persons.

The new home of the Company will have a frontage of 160'6" on Second St. and on New Anthony St. with a frontage on Mission street of 112 feet and the north end fronts on a private street. It is to have six stories with basement and attic.

The main entrance will be in the centre of the Second street facade, and will lead the patrons through a finely tiled vestibule wainscoted with beautiful marbles, to the elevators, of which there will be two rapid running for passengers and one for freight.

The fronts on all four streets for first and second stories will be in Raymond Granite, the exterior walls above the second story will be in gray bricks and Terra Cotta. The building will be as near fire proof in its construction as it is possible to make it, and the floors and waincoting throughout the corridors will be of finest California marble. It is almost needless to add that the building in every department will be finished in a first-class manner with all the latest improved appliances.

The basement, first, second and third stories will be devoted to the Express business, and the upper three stories divided off into offices for renting.

Richardson & Gale have the contract for the brick work. Mr. R. Keatinge has the contract for the fire-proofing construction which is being done under the Ransome system.

The patent fire-proof ceilings and partitions used in this structure are furnished by the California Artistic Metal and Wire Co., San Francisco.

THE NEW CHURCH of the Holy Cross, of which our illustration is the accepted design, will be erected on the North side of Fddy street between Devisadero and Scott streets.

The Church will cover a lot, seventy-six feet front by one hundred and thirty-seven feet, six inches in depth.

It will be unique in character because of the fact that it will be the first Catholic church in the City of San Francisco, with the interior structural work of steel and the exterior entirely in stone. The total cost of the church will be $50,000. The church will have a seating capacity of seven hundred and fifty, and the interior will be of such arrangement as will permit of a clear auditorium space, an uninterrupted view of the sanctuary from all portions. It will be ornamented in front with two stately towers of equal height, both running to a point 150 feet above the curb. The center will be emphasized or ornamented with a magnificent classic portico, supported by six lofty monolithic columns, 22 feet high and 2 feet in diameter, with ornate capitals. The portico is crowned with a grace pediment extending from tower to tower, drawing all parts into perfect union, creating a harmonious *tout ensemble*. The interior will be of elegant design and fine proportions. The sanctuary transepts and side altars being crowned by ornate arches 28 feet in width, connecting with an arched colonnade, which extends from the transepts to the entrance of the church. The entire interior will be lighted from above by windows placed in the clear story walls. There are no windows in side aisle walls, thereby affording the greatest amount of clear wall space for decoration in the future.

The Colusa Sand Stone Company have the contract for the stone work and Colusa sand stone will be used throughout the church.

A PERSPECTIVE view of residence, building for Alexander Young, Adams and Vernon streets, Oakland, Percy & Hamilton, Architects.

THE ELECTRICAL WIRING OF BUILDINGS.

IN THE *National Electrical Code*, the Rules and Requirements of the National Board of Fire Underwriters for the installation of wiring and apparatus for Electric light, heat and power, architects will find a safeguard that will protect them at every point, providing always that they post themselves sufficiently well with the rules and requirements that they may know on sight whether the contractor is complying with the specifications or not. It is not to be expected that architects will in their specifications enter into all the minute details for wiring, but it is to be very much to their credit when they specify "according to the rules and requirements"

of the National Board of Underwriters, and are in themselves sufficiently familiar with these rules to pass upon the contractor's work.

This solution of the difficulty is the only true one, and architects will find that the sooner such a course of procedure is put in force the sooner this vexed question will be satisfactorily settled.

Among the "General Suggestions" that are printed by the National Board, the following one for Architects is to the point:

"Architects are urged, when drawing plans and specifications, to make provision for the channeling and pocketing of buildings for electric light or power wires, and in specifications for electric gas lighting to require a two-wire circuit, whether the building is to be wired for electric lighting or not, so that no part of the gas fixtures or gas piping be allowed to be used for the gas-lighting circuit."

Had the Architect of the California Hotel specified, "according to the National Electrical Code," the Electrical Contractor's work there would have been of a very different order, and the fire that might have destroyed the premises been avoided. As it was, the wires were run across and so near the heavy iron gas mains beneath the old Kitchen floor, that the same old usual result happened — wires grounded on the iron gas mains and, of course, fire in the Kitchen floor. The only thing that saved the north wing of the Hotel from annihilation was a mere lucky incident — the Engineer's opportune appearance in the Kitchen.

To avoid these dangers to life and property is the clear duty of every Architect.

[The Editor is not responsible for anything which appears in this column.]

To the Editor of the California Architect and Building News.

Gentlemen:—I saw in your February issue an article in reference to fire-proof materials that were tested in the New Wells, Fargo & Co.'s building on Second street. However the test was made I do not know, but I can say that the people who made the test came to the conclusion that concrete material was fire-proof. I would like to ask for information, gentlemen, what the word fire-proof means. Does it mean something that will not light by the application of a match or something that will stand a limited amount of heat—say 1000 degrees Fahr. Now let me ask the gentlemen who were present at the test, how many degrees of heat were raised about the so called fire-proof material and if a stream of cold water was turned on it after it was heated up. Or how do these gentlemen account for the fact that concrete is fire-proof when the principal ingredients will not stand over and above 300 degrees Fahr. Is there any chemical action that takes place after the ingredients are mixed and the mass has set? If there is it is something very unnatural. The principal ingredient of concrete is rock—that is blue trap rock and Portland cement, which disintegrate (after being mixed together forming with the addition of sand or gravel and water what is called concrete) when subjected to a heat of 300 degrees Fahr. In all big fires without exception it has been proven that the only materials that will stand fire without serious damage is burned clay, i. e, brick and terra cotta. It is now about four years since we had a fire that would bear me out in my argument. If people who observed the ruins of that fire near Fourth and Brannan streets about four years ago, and took particular notice, they would have seen all the concrete sidewalks destroyed in front of frame buildings, which had been burned down. The new St. Roses Church, then in course of construction, was damaged by the fire destroying the granite blocks and artificial stone or concrete trimmings, while not affecting the brick-work at all except drying it a little. The only thing that can be fire-proof is a material that has been already tested or burned. Now any kind of clay ware has to stand at least 1500 degrees of heat to be burned—while the genuine terra cotta fire-proofing has to stand about 3000 degrees Fahr. before it is marketable.

Hoping that my question may be answered, which is—What is fire-proof material? I remain,

Very truly yours,
W. A. Butler

MODERN APPLIANCES IN QUARRIES.

The huge beds of stone upon which the two magnificent palaces of the Champs Elysees are to be erected, begin to make their appearance above ground. These two buildings will border the "Grande Perspective Nicolas II." at the Universal Exhibition of 1900. How will it be possible to construct so speedily these imposing monuments destined to remain after the exhibition among the architectural beauties of Paris? We can readily understand how the architects, men of undoubted talent tested by numerous competitions, to whom the work was entrusted, imagined, studied and planned these palaces with marvellous rapidity; but the materials themselves, the stones which form the bulk of the work, how can they be obtained in time, drawn in huge blocks from the quarries? Here is a very interesting object lesson, in which is revealed the power given to human labor by mechanics with its admirable utilization of forces. It is by the cutting, transport and piling of huge blocks that the successive stages of civilization have marked the extent of their grandeur. Are not the obelisks and pyramids a cause of admiration and wonder even to people of the present day? How was it possible for pure manual labor, even when carefully distributed, disciplined, subjugated, to hew those gigantic stones and then move them into their final resting-place? Important works have been written on the subject, from which it appears that the inclined plane and the wedge

no less than patience and length of time contributed to remove these difficulties. But fundamental documents are too frequently denied to seekers; perhaps they were lost, to our deep regret, in the famous and silly destruction by fire of the famous Library of Alexandria. The present generation has consequently been obliged to begin all over again. Very fortunately, steam and electricity have given it perfectly new means of action of such power as to be able to rival the buried secrets of ancient engineers.

A striking example is furnished in the working of quarries where electricity, now co-operating with the steam, wins victories of power of great value. Work must be smart in the cutting of a bed of stone in quarries. The architect who has ordered the ashlar and arch-stones is always in a remarkable hurry. Besides, one has to work in the open air, amid the dust in fine weather and under the pelting rain in bad. The steam engines scattered about the quarry were often injured by such a state of things; they became clogged, suffering from a kind of engine rheumatism, afflicted by untimely condensations, a kink of pulmonary apoplexy, and uttering heart-rending groans, not, however, stone-rending.

With this pliant electric conductors all these inconveniences vanish in many cases. In the great quarries of Euville, for example, for the work of extraction, the machines which cut the stones are electric, the work-yards are lighted by electricity, and water is raised by this same means to a height of 60 metres to feed the boiler of the little steam motor which is situated at the end of the big rolling bridge and raises the stones through space. From an already long experiment it is estimated that a great final saving is thus obtained.

In the quarries of Hainault, also famous, there is a rolling bridge of 60 metric tons power which raises the biggest blocks. It is worked by steam, but illuminated by electricity, and served continuously by pumps, windlasses and electric cranes. The annual production of a quarry exploited in this way is estimated at 20,000 cubic metres of granite. We may also mention the instructive case of the Soignies quarries. When boilers and special motors were employed for the various machines situated in different parts of the work-yards which are about 52 hectares in area, the consumption of coal was 4 to 5 kilogramme per effective horse-power. Since adoption of electricity the consumption of coal fell below one kilogramme per horse. It is a result not to be despised, and which demonstrates the utility of classing motive power. Let us add that, thanks to these powerful electric machines, the time requisite for extraction of stones and their employment has thus been greatly reduced. To build a big monument, palace or imposing edifice of any kind we had formerly to reckon on long delay in extraction, without mentioning the time required to dry the stone and render it frost-proof. The time of drying is about the same with the new rapid methods of extraction; but circumstances change. It is quite a different affair to dry a stone which for months has been subjected to the inclemency of the weather and that which is removed and placed under shelter in a few days.

It is to this powerful and improved extracting plant that the Exhibition of 1900, being now prepared on a scale of incomparable grandeur, will be indebted for the sudden appearance of its palaces above ground, recalling to mind the mythological legend of Orpheus charming the animals, rocks, trees; etc.

In fact, we here find a reply to the question made by Henri Heine: "Had not nature formerly a sensibility similar to that of man and perhaps more? The inspiring power of Orpheus, we are told, led away trees and rocks in a dance. Is such a prodigy possible at the present day?" If Henri Heine were conducted by one of the architects of our future Exhibition through the yards where the marvelous work is being executed he would no doubt exclaim, all poetical skepticism conquered, "The prodigy has happened."—*La vie Scientifique.*

THE CALIFORNIA UNIVERSITY COMPETITION.

AS OUR BRETHREN ACROSS THE WATER VIEW IT.

THE ARRANGEMENTS for this proposed great international competition have now assumed a definite form. The programme and conditions are comprised in a pamphlet of nearly forty pages, issued by the "The Trustees of the Phebe Hearst Architectural Plan," 217 Sansome street, San Francisco, but of which copies, we believe, can be seen or obtained at the Institute of Architects. It may be useful, however, to notice here some of the main points of the programme.

The competition is for a general scheme for the whole laying out of the ground and arrangement of the buildings, "the guiding thought of the entire undertaking," so that, although the whole cannot be carried out at once, those buildings which are erected from time to time may all be carried out as portions of one great design. The competition will be a double one, Preliminary and Final; the final competition, as usual in such cases, being between a limited number of competitors selected from the preliminary competition. It appears, however, that even the preliminary competition will be a matter of considerable detail, as the "general plan" will indicate all the buildings in detail, and not in block only, to a scale of 100 ft. to the inch. The other drawings will be a general elevation and a general section, to the same scale as the plan. The authors will each use his own judgment as to which points of the design he will take for his section and elevation; and as each competitor is to be allowed full liberty to arrange the buildings and sites as he thinks best, it would be difficult to specify any special line for the section or elevation.

The jury will select not less than ten plans from the preliminary designs, but have power to select more. If only ten are retained, their authors will each be entitled to a premium of 300*l.*; if more than ten and not more than fifteen are selected, the premium will be 240*l.* each; if more than fifteen are selected, 200*l.* each. This arrangement seems rather illogical, from the point of view of the architects, as one cannot see why any one man should receive less for his labour on account of the proportion of merit in the other competitors; and as there seems to be plenty of money, we should suggest that it would be much more fair and logical to give the same premium to all those whose works are selected for the final competition, independently of their number. The premiums are not, however, to be paid at once; one third of the sum is to be paid down, and the remainder after the competitor has sent in drawings for the final competition. This is, however, independent of the premiums specially attached to the final competition, for which

a sum of 5,000*l.* has been set aside; of this at least 1,600*l.** will be awarded to the plan classed as No. 1, and at least five of the final competitors will receive premiums; but the jury retain the right of distributing the total allotment among a greater number of competitors if they think fit.

In the final competition a general plan, section, and elevation are again required, accompanied by a general perspective view, all the three latter, as before, to be taken at any point the competitor prefers. What further drawings may be required will be decided by the jury after the preliminary competition; they may require the competitors to give drawings of one division or set of buildings; to a larger scale, we presume, than that of the general plan, though that is not stated in so many words. We observe also that no statement is made as to the scale to which the general drawings are to be made for the final competition; as far as appears, they are to be the same as in the first competition; but the fact that the scale is not defined appears to be an oversight. The point is of some importance as an indication of the amount of work a selected competitor will have to go through before his chance of ultimate success in the final competition. If the scale for the general plans is to be the same, there does not appear to be any reason why a competitor might not send in his general plans again for the final competition, if he is entirely satisfied with them. In connection with this point, however, it may be mentioned that a competitor selected in the preliminary competition has full liberty to modify his designs for the final one, and is not obliged to adhere to his first scheme. All descriptive writing on the plans is to be on the rooms described and not in the margin (a provision, obviously, against the possible waste of time of the jury in referring to schedules and reference letters), and it is all to be in English; no other language will be recognised. For a competition open to all the continental countries we should have thought French would have been more convenient.

The preliminary competition is to be decided by a jury of architects, viz: Mr Norman Shaw, R.A (London), M Pascal (Paris), Professor Wallot (Dresden), Mr. Walter Cook (New York), and Mr J. B. Reinstein (San Francisco). We are rather surprised that the committee did not apply to Mr. Waterhouse to be the English representative on the jury; in that particular function his name, we should imagine, would command more confidence with English competitors (if there are any) than that of any other English architect, more especially as this is a case in which plan is of the highest and most essential importance, and Mr. Waterhouse is a master of plan. For the final competition the jury will be composed of the five members of the preliminary jury, and of four architects who will be chosen by the Phebe Hearst Trustees, assisted by lists of names proposed by the competitors who are selected in the preliminary competition, each of whom will be invited to send five suggested names, the four who have most votes to be selected, subject, however, to proper provision for the international character of the jury.

The preliminary designs are to be delivered, not in San Francisco, but to the care of the United States Consul at Antwerp, by July 1 of this year. No date is yet fixed for the conclusion of the final competition, but it is stated that the selected architects will have not less than six months given them to mature their designs; and they will moreover, if they wish to study the site, receive, under certain conditions, first class transportation and expenses for the journey from their places of residence to San Francisco and return; a provision both liberal and sensible. There is to be no exhibition of the general collection of preliminary plans, but after the final competition the final and preliminary plans of all those who take part in it will be exhibited at the Mark Hopkins Institute of Art at San Francisco.

The programme has been deposited at various centres in different cities, that for London being the Institute of Architects.

Such is the outline of the arrangements for this very exceptional and perhaps unprecedented architectural competition, concerning which it is difficult to predict whether it is likely to result in a grand success or a *fiasco*. The ultimate prize, for the man who comes out the winner in the final competition, is no doubt a grand one; but the work to be done for even the preliminary competition is so serious that it may be questioned whether many architects who are already in possession of a fair practice will care to go through it for the chance of selection to enter the final competition; for the premiums in the preliminary competition, though they may be thought liberal in comparison with ordinary competition standards, will by no means recompense the work to be undertaken. This will be realised at once when we say that the general plan includes no less than twenty-eight blocks of building, many of which must be extensive and elaborate in plan, and the plans of all of which must be given in as much detail as can be shown on the scale of 100 feet to an inch. The following is the list of these Departments, the requirements of which are in some cases drawn out at considerable length; we must content ourselves here with merely indicating the principal rooms required in some of the more important blocks:—

1. Administration: Including entrance to the University, offices of the president and secretaries, and for the meetings of regents and professors, reception-rooms, ante-rooms, committee-rooms, hall of records, etc.
2. University Library: For 750,000 volumes, with large reading-room, hall for papers and periodicals, study-rooms, etc.
3. University Museum: Provision for art, antiquities, ethnology, etc.
4. Auditoriums: Two, each adapted to lecture, concert, and theatre purposes, 5,000 and 5,100 respectively, and a garden arranged for celebrations and receptions.
5. Military Establishment: Four lecture rooms, library, museum, gallery of models and drawings of military works, armoury, drill field, etc.
6. Gymnasia: Two large halls for exercises, each with 200 dressing-rooms, and 100 shower baths; two swimming tanks, large field for athletic games, with stands and seats, "treated in a monumental and majestic style."
7. Printing and publishing Establishment.
8. Habitation: for 3,000 students, and for head of the Material Department and family, assistant doctor, superintendents employees and workmen, etc., and two dining establishments for students.
9. Club Houses: Four, with all modern appointments.
10. Infirmary.
11. Approach and Communication: Porticos, galleries or corridors, interior staircases, elevators, etc.; covered communications between the various groups.
12. Buildings for the General Service: A central plant for production of power, heat, and light; workshops; telegraph and telephone stations; warehouses; fire department tsation, etc., etc.
13. The Departments of Instruction in general; Various adjuncts required in all the groups—cloak-rooms, lavatories, department libraries, study-rooms, etc.
14. Department of Philosophy and Pedagogy; Eleven lecture-rooms, twelve laboratories, etc.
15. Department of Jurisprudence; Eleven lecture-rooms, etc.
16. Department of History and Political Science: Fourteen lecture, rooms, gallery of geographical maps, etc.
17. Department of Ancient and Modern Languages; Fifty-four lecture-rooms.
18. Department of Mathematic: Fifteen lecture-rooms and model-room.
19. Department of Physics: Ten lecture-rooms, thirty-one laboratories, with necessary adjuncts, tower for vertical experiments, long gallery for optical experiments, machine-shop, etc.
20. Department of Astronomy: Observatories for astronomy and meteorology, six lecture-rooms, dwellings for three astronomers and families.
21. Department of Chemistry: Three lecture rooms, thirty-one laborotories, and a long list of accessorp departments.
22. Department of Natural History: Ten lecture rooms, various laboratories and their accessories, dissecting-rooms, vivisection-rooms, large museum of zoological collections in three sections, microscopical laboratories, herbarium, botanical garden, etc.
23. Department of Fine Arts: Providing everything for the teaching of the Fine Arts; painting, sculpture, architecture, music;
24. Department of Agriculture: Seven lecture-rooms, many laboratories; museum for agricultural products, etc.
25. Department of Mechanical Engineering: This department includes electrical engineering. Eight lecture-rooms; eighteen laboratories; five drawing-rooms; three or four workshops. rooms for collections and models, etc.
26. Department of Civil Engineering: Accommodation similar to last department.
27. Deparment of Mining: Similar to No. 25; space and accommodations required for this department are about the same as for the Department of Mechanical Engineering; power supplied from central station.
28. Department of Draughting and Graphical Analysis: Nine drawing-rooms, model-rooms, etc.

Bearing in mind that in the above statement of the requirements for the various blocks we have only given the principal items, and omitted a great quantity of minor detail, it will readily be seen that this is a scheme which no man can adequately consider and sketch out plans for, even on the small scale demanded, between now and July 1, unless he put aside everything else that he was doing and devoted his whole time and thought to this one competition; and is it likely that any man who has a practice and has his living to make by it will abandon all his regular work for the sake of the chances offered to him here? The only people who are likely to go in for it are ambitious young men who have not got into practice, and who have enough to live on to support them while they are engaged in working out the California scheme; so, at least, the probability appears to us; and we do not suppose it was that class of architect which the promoters desired to attract. The promoters, in fact, seem to have been a little bitten with that disease of *megalomania* which is said by Nordau to be a special weakness of the present day; they have desired to have an architectural competition on such a scale as should throw all others into the shade; and they have gone beyond the limits of what it is possible to expect from competitors. They should have asked for a block plan of the site, with a sketch elevation and section, and detailed plans of perhaps two of the blocks, as an indication of the author's efficiency in the details of planning. With such a programme they might have attracted some of the most eminent architects from all countries. As it is, we very much doubt whether they will attract any such men. There may be still time to consider the matter and to announce such a modification of the conditions as we have suggested, through the Press, in such a manner that it should come under the eye of all actual or possible competitors; and the Trustees or their professional advisers would probably do well to take this point into consideration before it is too late, if they wish the competition to be a success. *The Builder, London.*

* In the programme the sums are given, naturally, in dollars; we give them here in English currency.

THE BEST FIREPROOF CONSTRUCTION FOR BUILDINGS OCCUPIED FOR MERCANTILE PURPOSES.

PAPER READ BY W. L. B. JENNEY BEFORE THE FIRE UNDERWRITERS' ASSOCIATION OF THE NORTHWEST.

CONTINUED FROM LAST ISSUE.

N VIEW of these important developments, it is our opinion that important structures of this class should have a radically different method of fireproofing. The fireproofing should be in itself strong and able to resist severe shocks, and should if possible, be able to prevent the expansion of the steel work.

There seems to be but one material that is now known that could be utilized to accomplish these results and that is, first-class concrete. The fire resisting qualities of properly made concrete have been amply proven to be equal if not better than fire clay tile, as shown by the series of tests carried on by the Building Department of the City of New York."

The Engineering Record of September 16, 1897, states that in the Denver test a floor made of end construction porous terra cotta endured eleven alternate applications of fierce flame and cold water, lasting 23 hours and finally endured a 24 hours continuous fire test and afterwards sustained a load of 12,500 lbs. which seems quite satisfactory still, personally, all things considered, I would give the preference to concrete.

From the experience gained in street railway construction in laying continuous rails, it is to a large degree possible to prevent the metal from expanding. In street railway work this has been accomplished merely by the adhesion of the pavement to the side of the rails. In building construction the same results could be obtained by encasing the columns and girders with concrete placed directly against the steel work. The adhesion of the concrete would to a large degree prevent unequal expansion of the concrete and steel. The floor arches should also be constructed of concrete but of sufficient depth to be able to resist lateral forces, except during a fire principally wind pressure. By the use of such floors with the prevention of injurious expansion and the protection of columns with materials that can stand severe shocks of any nature whatever the modern steel frame constructed building would be most thoroughly protected against any fire.

The construction herein suggested should not materially increase the cost of construction. The solid concrete about the colums would be added strength to same, and could no doubt be made self supporting. The same could be said of concrete surrounding beams and girders, as has been amply demonstrated by the strength developed by concrete iron constructions.

As so-called fireproof buildings are not equally and to the same degree, protected against fire, we would recommend to the insurance companies that they should vary the rate of insurance for this class of buildings, depending upon the character of the fireproofing used. The competition between fireproofing companies has been so severe as to reduce the price of their output, in very many instances at the expense of quality. The large fire loss in the Horne building would still have been larger had the fireproofing been of poor quality, and we would further recommend that the insurance companies have prepared standard specifications governing the character of the fireproofing and the construction and putting up of same, and requiring owners of buildings to use fireproofing subject to these specifications, under careful inspection, or be subjected to higher insurance rates."

Before answering the question—"What is the best fireproof construction"—I will call your attention to ahother class of buildings known as "Mill Construction" much in vogue, particularly in St. Louis. The Chicago building ordinance permits building of this class to be 100 ft. in height as against 60 ft. for common construction. The underwriters give them an advantage of rate indicating a less hazardous risk. Are these advantages justified by the facts? I think not. Mill construction as understood by the Chicago Building Department is thus described in the city ordinances—"The term 'Mill Construction' shall apply to all buildings in which all the girders and joists supporting floors and roof have a sectional area of not less than 72 square inches, and above the joists of which there is laid a solid timber floor of thickness not less than 3¾ inches thick. Wooden posts used in buildings of this class shall not be of smaller sectional area than 100 sq. inches. Partitions and elevator enclosures in buildings of this class shall be made entirely of incombustible material. If iron pillars, girders or beams are used in building of this class, they shall be protected as provided for fireproof building; but the wooden posts, girders,

and joists, need not be protected by fireproof covering. The use of wood furring wood laths or steel partitions, shall not be permitted in buildings of this class."

On the 15th of March last there occurred a big fire in the heart of the wholesale district in St. Louis, a building occupied by the Ely-Walker Drygoods Co. Quoting from the St. Louis *Democrat* of the 16th of March, "the loss will be close on to $1,500,000.00. One human life was lost and several people hurt. The fire was one of the worst the St. Louis fire department has had to cope with for a long time and for a time it looked as though there was to be a conflagration that would wipe out the Washington avenue wholesale district. The firm's enormous stock had been recently increased by large purchases of the finest lines of goods in the market, consequently every inch of available floor space was occupied by great piles of dry goods of every description for the spring trade." Desiring to obtain reliable information in regard to the character of the building burned I wrote to W. S. Eames, of Eames & Young, architects. Mr. Eames replied immediately as follows:

"In regard to the recent destructive fire in our city, I beg to send you under separate cover two newspapers which contain very graphic and accurate descriptions of the fire, the amount of damage, the character of the contents of the building, etc. The fire began about half past seven on Monday night, and while I am dictating this letter I can see from my window the engines still attempting to quench it. Portions of all the walls remain, but the building is a total loss unless it be the foundation and the walls of the first and second stories. The building was not a fireproof building in any sense. It is what is known by the St. Louis Board of Fire Underwriters as "a standard slow combustion building." I enclose a printed specification for such buildings as issued by our Board of Underwriters. The building in question complied with all of the requirements of this specification except as to area and height. The building is about 120 ft. square and seven stories in height. It had three street fronts and a blind wall on the other enclosing side. The two principal street fronts were faced with Long Meadow brown sand stone. It was one of the last works of the late H. H. Richardson, and was of course Romanesque in style. Of course the stone work of the two street fronts was principally Ashlar backed with brick work. The building was constructed by Norcross Bros., of Boston. The basement, first and second stories, I think, had cast iron columns enveloped in fire clay casings plastered. The remaining columns were of southern yellow pine. The wooden girders, wooden floor beams and heavy planking were of Long Leaf Mississipppi or Louisiana pine. The building was not equipped with automatic sprinklers and to this defect is attributed the loss of the building and its contents. The stairways and elevators were enclosed in brick shafts with standard metal covered doors to all openings.

The fire burned for about three hours apparently entirely within the building. Then came a collapse (which probably was caused by the fall of the burned wooden posts) whereupon the fifth, sixth, and seventh floors and the roof fell in and created an opportunity for a tremendous conflagration. The enormous mass of heavy dry seasoned beams and flooring made an irresistible fire with a heat of great intensity. The first, second and third floors are still in position but of course the intense heat has damaged what remains of the walls, and the contents of the building are a total and irreparable loss.

Most of the commercial mercantile building in this city have for the past seven or eight years been constructed upon the slow combustion principle. The reason being that the Board of Underwriters gives a rate on such construction that makes it profitable to the owner of the building as well as the occupant. Nearly all of the buildings in the Cupples Block, of which we were the architects, are buildings of this type of construction. But special constructive features have been added to the requirements of the underwriters and the entire plant is thoroughly equipped with the very best system of automatic sprinklers."

The specifications of the St. Louis Board of Fire Underwriters for mill construction, although more in detail, do not differ materially from the Chicago city ordinances, which were quoted. In these buildings there is no lath and no plaster, hence, no covered passages, so that the fire is entirely exposed to the direct action of the fire department. This is certainly an advantage at the outset of a fire. It also enables the fire department, after the fire is well under control, to extinguish it entirely. There is no opportunity for the fire partially extinguished to be hidden under lath and plaster and to break out later. To this extent the system is advantageous but under the conditions under which the Horne building was placed—the raging fire across the street to windward, inflaming the goods in every store at the same instant—mill construction feeds the flame and causes total loss in an incredibly short time. Several Boston fires, the Jenkins building at Pittsburgh, as well as the St. Louis fire, have shown that no advantage as against loss can be expected from this class of construction. The timbers add so much fuel to the flames after the fire is once under way. In these buildings we meet another difficulty. The long heavy timbers required for that construction can be obtained cheapest and easiest in southern or pich pine. Moreover, this material is usually considered to carry a heavier load than oak. For example, a 10 in. x 10 in. post in Georgia pine would require by formulæ in general use to be 11 in. x 11 in. if in oak. Oak is much safer from fire but unfortunately cannot be obtained of the requisite dimensions and moreover costs about 50 per cent more per thousand, than southern or pitch pine, which can be obtained free from knots direct from the mills smooth dressed to the sizes demanded, hence, this is the material usually employed for such buildings. This southern pine, often called pitch pine, is as its name implies full of pitch. It is the most inflamable of all the usual building materials. The pitch distils out by heat and rapidly catches and spreads the fire with rapidity, so that the usual so-called "Slow Burning Construction" often used as a synonym for "Mill Construction" is a misnomer and offers no protection against the burning of a stock of goods beyond the ordinary common construction and is not entitled to any reduction in rate. Indeed, when pitch pine is used, I should be inclined to place this construction as extra hazardous as the building could be set on fire by the burning of a newspaper or by a gas jet flaming against the wood. Such a fire once started usually feeds itself and spreads rapidly over the entire building. I also object to the use of southern pine for the floors and interior finish of apartment houses as unnecessarily hazardous, for there is no doubt but what pitch pine helps along a fire and greatly increases the loss above what it would have been had oak been used instead of the pitch pine.

The Jenkins building at Pittsburg is reported by the Insurance World as of mill construction. Also the store in St. Louis occupied by the Ely-Walker Co., and many of the Boston buildings.

To be Continued.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

411 MISSION ST., Bet. 1st and Fremont, SAN FRANCISCO, CAL.

BEST FOR WARM CLIMATES

Cannot Crack or Peel as Pain Does.

Being *in* the wood, and not wholly on the surface, like paint.

CABOT'S CREOSOTE SHINGLE STAINS

wear better and longer in warm climates than paint, which cracks and peels off under the hot suns. They are the only exterior colorings that do not turn black, and the only treatment that will prevent the blackening of Redwood. No other Stains can contain Creosote, "the best wood preservative known," our patent giving us the sole right to make, sell or advertise Creosote Stains.

The *Siding* of the Kip Mission, above, is Creosote Stained.
Samples and prices on application to

FACTS ABOUT PAINTS.

PHŒNIX

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

PURE

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

PAINT

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.

CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAUSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

Price, $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

☞ CLAWSON'S PATENT THIMBLE.

Mission near 2d. Iron, steel work, etc; o. Wells, Fargo & Co; a. Percy & Hamilton; c. Joseph F. Forderer; signed, March 26; filed, March 28; cost $12,624.

Oak near Laguna. To build; o. George J. Anderson; a. D. V. Deuel; c. Pettersen & Persson; signed, April 2; filed, April 4; cost $3100.

Railroad Ave. near Oak. Two-story frame; o. B. Vergez and A. Methebat; c. C. A. Henderlong; signed, April 4; filed, April 5; cost $3800.

Second and Mission. Ornamental cast and wrought iron work; o. Wells, Fargo & Co; a. Percy & Hamilton; c. Winslow Bros. & Co; signed, March 19; filed, April 4; cost $28,000.

Second near California. To build; o. Miss Mary McQuaid; c. John Keneally; signed, April 6; filed, April 7; cost $2675.

Scott near Broadway. Two-story frame; o. W. F. Herrin; a. Julius E. Kraft; c. Anderson & Greig; signed, March 17; filed, March 23; cost $6973.

Stockton near Vallejo. Two-story frame; o. Hirsch Bros.; c. H. P. Conrady; signed and filed, April 6; cost $4500.

Sutter near Taylor. Alterations and additions; o. Mrs. Mary A. Gaffney; a. Kenlizer & Barth; c. Hannah Bros; signed and filed, April 4; cost $2300.

OAKLAND

Sixth and Alice. To build; o. Henry Hennings; a. McNally & Stoufey; c. A. R. Denke, Sr; signed, March 23; filed, March 24; cost $4350.

Adeline and 10th. Additions and alterations; o. M. Jones; a. Chas. Mau; c. McCracken & Lee; signed, and filed, March 8; cost $2400.

Tenth and Broadway. To build; o. John Lancaster a. J. Conant; c. J. M. Shay; signed, March 30; filed, March 31; cost $4157.

Butler Ave. near Idaho. To build; o. Wm. J. Elfert; a. John J. and T. D. Newsom; c. J. House; signed, April 7; filed, April 8; cost $1800.

Club House. O. Piedmont Development Co; a. D. F. Oliver; c. H. C. Canfield; signed and filed, March 21; cost $2988.

ALAMEDA

Pacific Ave. near Chestnut. Brick and carpenter work; o. Thos. H. Kelly; c. Theo Victors; signed, April 2; filed, April 9; cost $1840.50.

BOLINAS

To build. O. Bell C. and Grace Nichols; a. Oliver Everett; c. Edward Bletch; signed and filed, April 6; cost $1344.

ROSS STATION

Dibble Tract, lot 10. Cottage and barn; o. Edward G. Schmeidell; a. Geo. H. Howard; c. Thos. O'Connor; signed and filed, April 7; cost $3900.

SAN RAFAEL

B street. Cottage; o. C. A. Burkhardt; a. B. A. Brown; c. Thos. O'Connor; signed, April 4; filed, April 6; cost $1350.

By a decisive vote at a recent election here, it was decided to issue bonds to the extent of $15,000 for the purpose of erecting a High School building.

SAUSALITO

On grounds of El Monte Hotel. To build one-story frame dancing pavilion; o. Excelsior Loan Association; a. B. A. Brown; c. J. Strittmatter; signed, April 5; filed, April 6; cost $1350.

BERKELEY

Bancroft Way near College Ave. Two-story frame; o. Lloyd Tevis; a. A. S. Smith; c. Anderson & Stockholm; signed, March 28; filed, March 31; cost $2428.50.

Humboldt Ave. and Prince street. To build; o. Walter Deakin; c. C. M. McGregor; signed, April 11; filed, April 12; cost $1041.

Telegraph Ave. near Durant Ave. Two-story frame o. C. L. Tilden, T. H. Bishop; a. Edward B. Seely; c. Kidder & Copper; signed, April 6; filed, April 7; cost $7727.

BUILDING NEWS.

LOS ANGELES

Henry D. Thompson has purchased the southeast corner of Sixth and Bonnie Brae streets, and is having a plan prepared for a suitable residence.

H. B. Hubbard has purchased a lot on Alvarado street, between Tenth and Eleventh streets, upon which he intends erecting a two-story residence.

Architects Ferris & Kronnick are preparing plans, for James Christie, of a six-room cottage, to be built at Pico Heights.

Architects Bradbeer and Russell have prepared plans for Morris Klein of a six-room cottage, to be erected on Tenth and Union avenues.

Architect R. B. Young, has prepared plans and taken bids for a two-story frame building 50x96 feet, for the Pacific School of Osteopathy. The location may possibly be the corner of Tenth and Figueroa streets.

Architect F. L. Roehrig has prepared plans for the Southern California Savings Bank, for extensive alterations to the southeast corner of court and Spring streets, by which they will occupy when completed the entire ground floor of their bank building.

Architect John P. Krempel is working on the detail drawings for the sugar house of the Oxnard beet sugar factory at Oxnard. Its dimensions are 400x120 feet; steel frame, expanded metal and fire-proof floor construction. The window frames, 360 in number, will be constructed of galvanized iron, and galvanized corrugated iron will be used for roofing. The steel frame work is well advanced, and work on the brick walls will commence shortly.

Architect A. M. Edelman has prepared plans for the estate of S. Heilman of a two-story business building 32x80 feet, to be built on the west side of Main street near Third street.

Architect Edward Neisser has let the contract for the erection of four flats, located on the east side of Olive street, between Tenth and Eleventh streets, to E. C. Shipley.

Architects Bradbeer and Russell have prepared plans for Mrs. E. Woolacott, for a five room cottage to be built on Central avenue, between Seventh and Eighth streets.

Architect H. F. Starbuck is calling for bids for a church building to be erected on Thirtieth street by the congregation of the Knox Presbyterian church.

Architect C. L. Strange has preparrd plans for a two-story 10 room residence, cobblestone foundation natural wood inside finish; to be built on Burlington avenue.

Architects Bradbeer and Russell have prepared plans for a two-story frame for Dr. Jones, to be built on Olive between Second and Third. The same architects have plans for cottage to be built on West Ninth street.

Architect Frank D. Hudson has let the contract for the foundation work of a 4-story and basement brick business building, to be built on the east side of Broadway between Third and Fourth streets.

BUILDING NEWS.

Architects Reid Bros. 401-402 Stimson block have plans and specifications of the new Douglass building all ready for bidders. The building will be 5 stories and basement; the elevation will be either stone or pressed brick and terra cotta; steel columns and girders throughout; wood floor joists, forming a semi-fire-proof structure. Inside finish may possibly be oak.

Martin Bekins, the proprietor of the Van and Storage Co; is about to erect an addition to his brick warehouse at Fourth and Alameda streets, it will be 50x150 feet, and two stories in height.

Architect Krause and Jenkins are preparing plans for Willard Sheldon of a two-story frame; concrete foundation, plastered outside, Spanish tile roof inside finish of oak redwood and yellow pine; to be built on the corner of Twenty-ninth and Menlo avenue.

Architect A. Benton has prepared plans for a new church for the St. John's Church, Episcopal of San Bernardino; it is to be of the perpendicular style with corner tower; side cloister; seating capacity 250; frame building; open timber roof; pine and redwood finish.

A Turkish hotel will be built on Grand avenue between 1st and 2d streets; cost $10,000; architect, A. J. Kosby he is now preparing plans.

BAKERSFIELD

After taking off 30 feet from the proposed plans to his bath house, Mr. Offer has awarded the contract of Geo. Robinson for $4110.

CATALINA ISLANDS

Architect C. H. Brown is preparing plans for the Catalina Yacht club, of a club house, to be built near the pavilion at Terminal Island, it will be 60x100, two stories, and surrounded by a porch 12 feet wide; the first floor will contain a ball room 35x58 feet.

SAN DIEGO

Building permits have been granted to W. R. Rogers for a residence at Seventh and Stevenson streets; to cost $3500.

S. E. Cofes has been granted a permit to build a cottage at Third and Olive streets to cost $1900.

The contract was awarded yesterday for the construction of M. V. Carrol's residence at Fifth street and Robinson avenue.

POMONA

Architect R. B. Young is preparing plans for the Sisters of the Holy Name, of a two-story frame academy building 65x100 feet, to be erected on the corner of Holt and Illinois avenues, Pomona.

RIVERSIDE

Frank A. Miller who intends erecting the new building which will be used jointly as a hotel and court-house, has asked for an extension of time to October 1st, pending the arrival of Walter Raymond from the east.

AUBURN

J. Ford has commenced a five-room cottage. J Thorn will build a three room cottage on the Huntley tract.

Mrs. Champman is building a small cottage.

John Chisholm will build a five room cottage on Linden Heights.

Mrs. I. M. Power will build a small cottage for rent.

Contracts not let and no architects plans accepted for any of these.

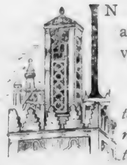
VOLUME XIX. APRIL 20th, 1898. NUMBER 4.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.



IN THE Architects Code of Ethics is an article of very general adoption by the various chapters of America.

It reads about as follows:

Although employed and paid by the owner to protect his interests, the architect should remember that exact justice must be maintained between both parties to a contract. He should so conduct his practice as to maintain and foster a higher and better standard of construction; and to encourage the employment of a better class of skilled contractors and workmen in every department.

Another article of equal strength and general adoption in the Code says:

A number of the architectural profession is found to maintain its honor, and to labor earnestly to extend its sphere of usefulness.

These articles are perfectly right and proper but we feel it clearly within our province to point out the fact that in the matter of plumbing inspection a goodly number of the profession in this City have become sadly forgetful of the existance of the foregoing precepts in their Code of Ethics.

It has become almost a uniform practice to specify the grade of bathtubs, the quality of closet and brand of kitchen sink, etc., etc., then finish the specifications by inserting this clause: "all other plumbing and drainage must comply with the rules and regulations of the Board of Health"—while we have no particular objection to offer to this mode of getting the plumbing contracts into municipal shape—we do most strenously object, to the practice of requiring from the contracting plumber a Board of Health certificate of inspection as a condition to a contract. And our objection to this mode of proceedure is fully sustained by the Ethics of the Code, wherein it says: "Exact justice must be maintained between both parties to a contract."

How can exact justice be maintained for the owner when an architect delegates to a plumbing inspector a duty that is clearly and specifically within the lines of his responsibility.

These inspectors are but human, and it is human to err, and we, who know their little peculiarities well, know that they were never known to err on the side of the owner.

These specifications, which read according to the rules, etc., etc., with the certificate of inspection clause as a condition to the contract, are to the plumber—who knows a thing or two about politics, and who has a friend at court—a source of considerable profit, as they are also to the inspector detailed on the building. But to the plumber who

figures on just what the rules and regulations call for, who is without a close political connection—as he is without the "useful friend at court"—that "certificate of inspection," as a condition to the contract, becomes a bugaboo of insurmountable proportions.

Mark the result, the political plumber banking on his financial and political affiliations with the inspector—more particularly the former—and knowing the exact cost to his competitors for the work as specified, complacently sends in a bid below the actual cost of the work, which when completed is as complacently accepted by his friend the inspector.

Who suffers? The non-political plumber—an honest man as plumbers go—loses caste and business and the architects' confidence in his ability, through no fault of his own. The architect should suffer through loss to his self respect; the owner becomes a sufferer because of the trust he has reposed in the honor and Ethics of the profession supposed to be embodied in his particular architect, to whom he has also entrusted his property and his money.

It is to the architect and to the architect only, that the owner looks for protection; as an employer, the owner expects, and has every right to expect, that exact justice shall be maintained between himself and all parties to contracts entered into for him, by his architect. But this practice of deliberately delegating to an open-handed free-lance inspector, a duty which the Ethics of his profession and his honor as an architect demands shall be performed by himself, certainly cannot be construed by any stretch of the imagination, as obtaining exact justice for any one, nor of maintaining the honor of a profession that should be beyond all else honorable.

THE STEEL SKELETON IN HIGH OFFICE BUILDING CONSTRUCTION GIVEN ITS INITIAL EARTHQUAKE TEST.

THE Earthquake which arrived at 11:42:44 on the night of March 31, last, according to all authorities was by far the severest experienced in this city since 1868. Prof. Lenschner, Director of the Observatory at Berkeley, in reporting of its intensity says: "It must have vastly exceeded all prior shocks in a horizontal direction." So of its severity there can be no doubt.

To be able to furnish to the world at large, and the building world in particular, the initial earthquake test of stability for the steel skeleton constructed high office buildings is now the proud lot of San Francisco.

It is, of course, only meet and just that where a condition of such vast importance as this arises, detailed reports of the effect of the shock upon the high buildings of the City, should be given to the world at large by the men who are responsible for their stability. Therefore the Editor of this Journal submits with much pleasure the following letters upon the subject:

To the Editor of the California Architect and Building News.

San Francisco, April 22, 1898.

Dear Sir—Your favor inquiring as to the noticeable effect of the recent earth-quake on tall buildings of steel skeleton construction, is received.

In reply would say that the Claus Spreckels Building, having a base of 70'0"x75'0" and a height of 315 feet, i. e., having a height of four and one half times its base, has shown no signs of damage.

The closest inspection reveals no cracks, either in stone, mortar joints or plastering. No glass has been broken although some were bent plates of large size (72"x132").

The elevator guides are perfectly true, showing complete recovery from any movement the building may have been subject to.

We have mentioned this building particularly, believing it offers the best proof of the complete immunity of well constructed buildings from damage, from our occasional seismic disturbances.

Other buildings, above the usual height, in relation to their bases, coming under our observation, show no evidence of harm.

Very sincerely yours,

Reid Bros.

To the Editor of the California Architect and Building News.

San Francisco, April 15, 1898.

Dear Sir:—In regard to the last serious earth-quake and its results on high buildings which have been erected under my supervision, I beg leave to state, that having never been in favor of high buildings and never having constructed any buildings on the so-called steel or iron skeleton construction, I cannot give you any absolute information in regard to the effects of same. Have found no damage in any of the buildings which have been put up under my supervision further than slight cracks, especially where the wood partitions and brick walls are joined together, which condition of things have also found has occured in all steel buildings.

In one building only, a ware-house having a front composed of a series of arches which were tied together by very rigid concrete and iron woven panels was there any effect which amounted to anything like a damage, and there so slight, as to be of no consequence. In this case it is very evident that the main building had undergone a decided movement from east to west, during this movement, where unquestionably the piers and walls were out of plumb, the rigid panels caused the brick work to crack on the face, but on cessation of the shock, all these walls and piers regained their original position, now being perfectly true and plumb, and the building as strong as ever, as far as can be seen by very close examination.

Having examined personally fifteen or twenty large brick buildings, including the Telephone Building, the Otis Building, the Grosvner Hotel, and the building opposite the Grosvner Hotel, I found no traces of any damage done.

Yours very truly,

Wm. F. Smith, Architect.

To the Editor of the California Architect and Building News.

San Francisco, Cal., April 15, 1898.

Dear Sir:—In response to your favor of the 9th inst. requesting my opinion as to the effects of the recent earth-quake on steel-frame construction in this city, I am gratified to state that they have stood the test very satisfactorily. While none of us could have desired such an experience we have naturally been curious to know how a severe shock would treat the buildings in question, and it is comforting as well as interesting to observe that while the vibration must have been very marked the buildings show no damage from this cause. The hour of disturbance precluded any concerted opinion as to personal experiences during the shake, as the offices of the buildings were empty, but from the reports of the few people who happened to be on the upper floors of two of the taller structures I judge that force of the oscilation must have been in proportion to the height from the ground and possibly by reason of the rigidity of the steel-frame the shock may have been intensified.

One of the three office buildings in which I have had a professional interest rests on piles averaging twenty-eight feet, driven to hardpan, in which the estimated load is very much within the limit of subsidence for each pile. The occupants of the top story of this building had an uncomfortable shake up, but the building shows no damage.

As the several members of steel-frames are either cased in terra cotta or inbedded in the masonry, we have no ready means of observing the lateral or shearing strains, which are the especial points of interest to the architect, but the fact is demonstrated that in properly constructed steel-frame buildings an earth quake will leave fewer marks of its force than in the cases where the walls have been anchored to wooden beams in the ordinary method of construction.

Very truly yours,

Clinton Day, Architect.

Editor California Architect and Building News.

San Francisco, April 22, 1898.

Dear Sir:—Referring to your favor of April 9th, asking my general observations, together with the result of my examinations, upon buildings which I have built lately in San Francisco, of the effect of the recent earth-quake, I beg to state as follows:—

On the morning following the shock I visited several of the buildings in question, the first one being Mr. W. F. Whittier's residence on the NE. cor. Jackson and Laguna streets, and as far as the exterior of the building was concerned noticed no effect whatever. I did not go inside, but afterwards saw Mr. Whittier at his office and, upon inquiring as to any damage done, he said there was none except the shaking down of a few flakes of loose plaster. The only place that this occurred was on the wall side of the rear stairway where the plastering ran continuously from the first story floor passed and above second story floor. At the junction of the second story floor there are joists usually placed running horizontally and parallel with studding. These joists had shrunk and buckled the plaster off slightly, producing cracks, and it was the loose plaster from the cracks which was shaken down in a fine dust on the floor below. Otherwise no damage throughout the entire building.

In the W. S. Clark Building, NE. cor. Bush and Battery streets, I examined same carefully from top to bottom inside as well as outside, and was unable to detect the slightest damage, there being no cracks visible except such as could be accounted for by natural causes and which existed before the earth-quake occurred. This building is one denominated in the Fire Ordinances as Class B. It was built upon made ground, the foundation being piled. The piling of this building was rather peculiar, inasmuch as the original shore line of the bay of San Francisco ran diagonally from the NW. corner of the building to the SE. corner, thus cutting the lot in half, the Westerly triangle being upon firm ground and the Easterly triangle on mud. This I ascertained when piling, the piles in outer triangle being 60'0" long at the extreme NE. corner of the building and from thence running to SW. corner of building down to 14 or 15 feet in length. The building was originally calculated, however, very carefully, as far as weights were concerned and the same amount of load per square foot imposed upon the foundation in all cases. Whether this had anything to do with its stability I am unable to state positively, but I believe that it had a good effect in keeping the building free from damage. In other words, when the shock came, one part of the foundation being as strong as the other, the building moved as a whole and was not shaken in parts as would probably be the case were one part of the foundation less strong than another.

In the Hobart Building on Market street which I built twelve or thirteen years ago, and which was the first building in San Francisco to use partial steel construction, I noticed no evidence of disturbance on the exterior. I only looked at front however and did not examine the interior, as the building has since been altered and made into offices. Throughout the entire front, which is a very complicated piece of construction I did not notice any cracks whatever.

The Union Depot and Ferry House I examined very thoroughly and carefully throughout, and the only cracks I could find were at the junction of the tile partitions with the overhead beams, and in one or two cases the walls themselves had cracked and some of the plastering fallen off. The cracks at the junction of the beam and top of partition were caused, in my opinion, by there not being placed on the underside of the beams any means of fastening or steadying the tile wall. The original specifications did not provide anything and no steps were ever taken subsequently to fasten them. Had there been a 4" channel placed flat side upwards into which the partition could have been wedged, there would probably been no cracking.

The only other evidences of disturbance I found around the building was in the upper stories of the tower in SE. corner thereof, where a small crack, probably a sixteenth of an inch in thickness, made its appearance in second and third stories.

I examined very thoroughly the junction of the tower with the main building and found no cracks, which was rather remarkable considering the fact that this tower is 245 ft. high and must have vibrated considerably at the top. This would produce a crushing and grinding effect on its junction with the main building, but so far as I could see not the slightest effect was produced.

I examined particularly the grand nave, which is an open space 45'0" wide and 66o'0" long running about north and south, from which direction the shocks came principally. This nave is covered throughout its entire length and width with marble wainscoting in large slabs, there being a base about 2'0" high, then a plain space about 9'0" high, capped with a complicated marble cornice. I looked principally for evidences of disturbance in the vertical joints of the long slabs, which were, as I said before, 9'0" high and about an average of 4'0" wide. I was very much surprised to find that there was not even the slightest crack visible, the original pointing being all in place and no spawling of edges having taken place. This is more remarkable when it is

considered that the wall on Easterly side of nave between the piers is composed of heavy wooden studding diagonally boarded. It would seem that if any damage were to be done it would occur at these points, but, as I said before, nothing was visible.

In the Crocker Building where I have my office, I examined only the rooms which I occupy and found no cracks whatever. I do not think that any cracking was done or any damage on either the exterior or interior of this building, otherwise if there had been I would have heard of it.

Yours very truly,

EDWARD R. SWAIN.

Ca *Architect and Building News.*

SAN FRANCISCO, CAL., April 16, 1898.

DEAR SIR:—Your letter is at hand relative to the recent seismic disturbance in this City, and to general observations and results of examinations made upon high buildings, so that through the opinion of the architects in this city, your valued journal may be able to compare the relative value of the two systems of construction followed in our midst, viz., the old or solid masonry unfortified by metal skeleton, and the new, viz., combination of masonry and steel frame.

In answer I have simply and briefly to say that if you desire to investigate properly the true merit of a certain system of construction it would, I feel, be wisdom to take for example the structures, which because of their excessive height and limited ground area, will be most subject to oscillation from the effect of wind force and earth-quake shock, and should such structure be found to resist the greatest forces, lower buildings, such as the Mills, Crocker, etc., of same construction, with greater ground area, will cenrtainly be proof against the same acting elements and need not become a part of your investigations.

We have in our city two tall structures of comparatively equal height and ground area.

One, The Claus Spreckles' building, square in plan and complete in every detail, with a rigid steel frame, the perpendicular wall surfaces subdivided into panels of minimum height by heavy steel masonry floors and said wall panels again subdivided to the greatest degree by solid partition walls from ground line to uppermost point. It is a splendid example of our modern system of construction as applied to an office building.

The architect was afforded the opportunity, was provided with ample material, took advantage of the situation, proved equal to the occasion, and in a masterly manner gave to the city a building more limited in ground area when compared to its perpendicular than any other building perhaps in the world; beautiful in design and irresistible as far as known forces are concerned in its perfect stability as has been proved beyond question by the recent disturbance.

If The Claus Spreckles' building, therefore, has not been found wanting, the system of construction employed is certainly ideal, no matter what might have developed in other buildings of similar construction, of lesser elevation, for the fault could not be laid at the door of the system but the manner of its employment.

The second structure is the New City Hall Dome, for which I am responsible. It is circular in plan, of equal height, almost same ground area, and after similar system of construction as The Claus Spreckle's building, but incomplete as a perfect building in being destitute up to this date of many essential members, such as its solid floors and partition walls at every story height, all of which were provided for by me in original design, but not placed because o the lack of funds in the public treasury.

And while it is unfortunate and to be regretted that it has been impossible so far to find the way to supply these most necessary re-enforcing members in the Dome, that it might have become as rigid as was originally intended, and be able, thoroughly, to the very last degree to resist all such horizontal and upward forces, as of recent occurence, or of increased intensity, without slightest indications of effect, still the lack of same has now demonstrated the absolute necessity of these things being placed, and also produced ample evidence of the severity and tendency of the shock, which would otherwise be unknown, upon masonry not as yet perfectly re-enforced by steel, as above mentioned, and it also afforded evidence of the imperceptibility of the shock upon the frame itself and all masonry brought in proper relation with said frame from foundation to crown line, and emphasizing, therefore, in this case more than any other the crowning virtue of the steel frame in building.

The Dome, though circular in plan, has been designed originally from an interior point of view as a model office building, with steel frame so arranged that great solid floors may be placed every fifteen feet from base of first order up to the very summit, and each of said floors subdivided by partitions, and as The Claus Spreckels' building for example, without a single floor or partition from foundation up, (one great open shaft) would be robbed of a mighty and indispensible element of its present rigidity, just so is the Dome, at this date, (deprived of these vital members of re-enforcement) possessed of only two-thirds of the strength, rigidity and utility originally contemplated, and was, therefore, as is evident with such existing conditions, subjected during the late tremor to a many fold more serious trial than any other structure in this city or elsewhere.

My examination of the Dome developed these facts, that in every particular the steel frame was rigid, and that all materials in contact with same in perfect condition, but at the very centre of the Dome, because of the nature of the movement or forces, being deprived of the essential weight and horizontal or lateral bracing which would be afforded, as above mentioned floors and partitions, I found one of the terra-cotta wall panels somewhat cracked, which was the sum total of the injury done, and which could never have occured were the Dome entirely complete, as I have above described.

The Dome, therefore, was the only structure, of the many buildings of steel construction in this city, which, though severe as the trial was, bore the slightest evidence that the earth-quake had occured, and the strong reasons in this one particular case, why it could not be otherwise expected, and how it could have been and may yet be easily avoided, I have, I trust, clearly presented.

All other buildings throughout the City and State damaged in any way belong to the system of construction, viz., solid masonry. Hence it is evident to the general public, (for it could never be discussed in the profession), that in a city like ours, subject to periodical tremors like the recent one and perhaps two fold greater, that the only character of building to be erected, if we aim to possess the most perfect type is that of steel frame complete, supporting enclosing walls, if possible, at every floor line, and through which steel frame all weights are transmitted directly to foundation, and by which metal skeleton all parts throughout are perfectly united.

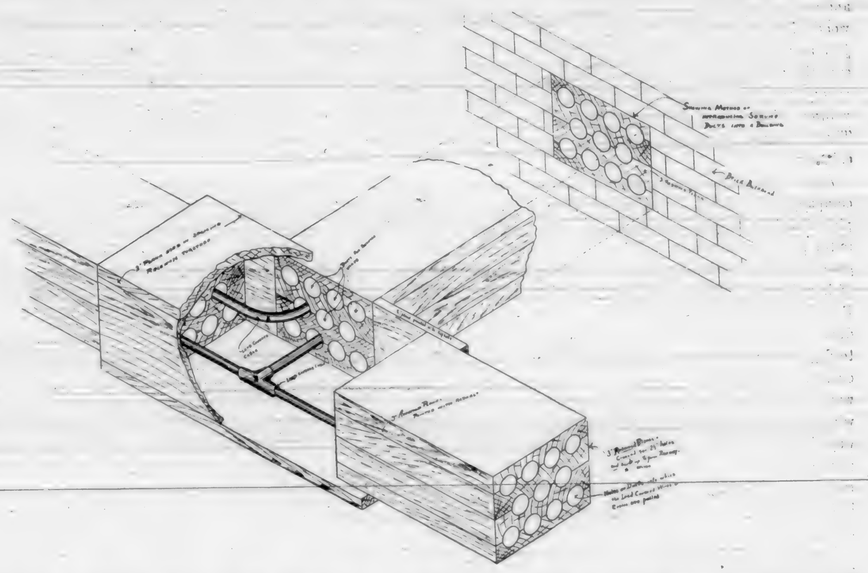
Respectfully,

FRANK T. SHEA.

HOW TWO WEALTHY CITIZENS BECAME EXPERTS IN TIMBER PHYSICS.

THE WORLD'S ELECTRICAL EFGINEERING EXPERTS GIVEN A LESSON IN ECONOMICS, AND INCIDENTALLY IN CONDUIT CONSTRUCTION

The business of selling electric current and telephone communications in large cities has acquired, as every reader of this Journal knows, enormous proportions. The tendencies of municipal legislation, growing more exacting each year, in opposition to the use of poles and all other known supports for overhead wiring, brought the companies who are in the business to stay strictly for the revenue there is in it, face to face with a problem, the solution of which was the underground conduit system. The placing of wires underground becoming compulsory within the limits of traffic congested districts, the question of doing so in the most effective manner conducive with safety to the life and property of others, together with the necessity for obtaining satisfactory results where space was very limited, access to conduits difficult, and where large consumption from many consumers made arrangement of construction very intricate, was a mathematical and mechanical problem that taxed severely the brains of many of the best electrical engineering experts that the world has as yet produced.



One of the greatest difficulties that continues to confront the companies engaged in the business for a legitimate profit, is that of discovering a material from which an ideal conduit may be constructed. The cost is of little consequence to such companies. Expense as an obstacle to the adoption of a conduit should never be considered.

Consideration should be given to, maximum of safety to life and property, minimum of danger to the consumer and to the companies' employees, and lastly, utility for the active service for which it is produced.

These surely are all the considerations that trustworthy men, acting collectively or singly, should allow to enter in judging of what constitutes the better conduit.

This leads to a short Wood digression, made necessary in order that the reader's mind may receive the right amount of preparation for the coming disclosures regarding the great discovery, recently made by two wealthy experts, long residents of this city, and neither of them heretofore suspected of expert knowledge in Timber Physics.

Until very recently no company in any city of the world using conduits for underground wiring service had utilized wood for underground conduits or raceways, as a means of distributing electric currents. This great discovery of wood as a suitable material for such conduits may open up a vast vista of wealth for the owners of redwood forests, and then again it may not.

However that may be, it is a substantiated fact that this great discovery was a simultaneous one on the part of the wealthy investigators. By the expenditure of two cents in postage, jointly contributed, they obtained from the Forestry Division U. S. Dept. of Agriculture the much wanted information, that the most important consideration had heretofore been given to Wood as a material of construction; they also found that the use of Wood as a substance which may be altered physically and chemically is far more important than is generally admitted. Immediately after carefully digesting—mentally—this wonderful piece of intelligence, the wealthy investment producers became imbued with a sudden and consuming joint desire to alter the physical and chemical properties of redwood as a substance

for underground conduits at the very least cost to themselves; but utterly regardless of the cost to the people at large or to fire underwriters in particular.

Among the enumerated physical properties of wood is "color" and "behavior after seasoning." These two physical properties these old sinners—experts, rather—very deftly altered by a burning process of their own, and a graphic description of this process is given in the accompanying description and diagram of the Alma Keith fire, a tenant of his honor, the Mayor.

This fire process through underground redwood conduits brought out some properties of the wood—asphaltum treated—which should attract the attention of the city authorities, as well as the fire underwriting experts. These are its intense propensity to produce dense and penetrating volumes of gases and smoke, under easy provocation. This property of the redwood of course interests the wealthy experts but little; it is just as well, however, to call their attention to it, otherwise something might be lost to them. Perhaps, another great discovery will be the outcome, whereby these penetrating dense volumes of gases and smoke may be turned to some account. The resources of the aforesaid wealthy experts being almost inexhaustive.

And in this Wood digression, with the aid of the accompanying diagram, showing graphically the method employed and the easy access through the open ducts, leading into the premises of patrons, for either fire, smoke, or accumulated gases, will be found the true story of the great discovery and of how it was that these streets underground of poor old San Francisco, became filled with redwood planks, grooved with ducts, piled one on top of the other, spiked together and made to do duty as underground conduits for distributing electrical currents by means of lead covered cables drawn into the raceways. The planks are generally about 3 inches by 12 inches, with 2½ inch grooves cut therein. This set of ducts or raceways is laid in the streets from the powerhouse along the various thoroughfares where it is intended to supply electric current for light and power. (Wherever a consumer along the line is secured, a service is introduced into his basement in a manner similar to the method shown by diagram.)

Every two hundred feet or so a brick manhole is located, having a cast iron top set flush with the paving. This manhole or junction box is installed to facilitate the drawing in and out of the various cables.

It is the custom when installing this system to install extra ducts—i. e., more than present needs demand—in order to have room for additional cables as business increases.

The matter of drawing in these cables is a safe enough proposition from an electrical standpoint, before the conduit has been cut or chopped into to make service connections.

The timber which composes this conduit system not having been laid on a concrete or other stable foundation, soon settles at these service points, and when the additional wires are drawn in the lead and insulation is torn or abraised by the sharp corners, thereby laying bare the conductor. The conductors may be conveying any voltage from 100 to 7,000 volts. It will be readily understood that with a potential anywhere near the latter figure a break in the continuity of the insulating covering will soon cause trouble. This was demonstrated recently in this city. Employees of the Mutual Company while drawing in the cables or in working in the opening in the ducts abraised the lead covering and injured the insulation to such an extent that the leak of current permitted thereby set fire to the asphaltum soaked ducts and soon had the lead melted and insulation burned off adjacent wires, and a general mix-up in the conduit was the result. From this point the smoke and gases traversed the raceways of a nearby service which terminated in the basement of Alma Keith's millinery establishment in the Phelan Building, and causing a loss to the fire underwriters of $1,200.

This same trouble is liable to happen at any time where conduits and raceways are installed in this manner.

Any conduit system employing open ducts is, in addition to being capable of conducting smoke and gases from a fire originating therein, a collector of other gases which have escaped from neighboring pipes conveying illuminating gas which permeates the ground, and if the joints in the conduits are not carefully installed, these may in a short time collect enough gas to become a source of great danger from explosions and fires.

It is from this fact that any company which connects such a system to the basement of a customer, with similar ducts, and does not seal up the ends of the raceways, should be held liable for any damage resulting from this criminal negligence. It might be further stated that the ducts which convey the cables from the main conduit to a basement should be of a fireproof material, certainly never of wood, made more inflammable by a coating of asphaltum. An iron tube with an insulated lining should be insisted upon by the fire underwriters' association.

While the street work may be without the pale of the insurance companies, it comes within their jurisdiction, and strictly within that of the fire marshal, when the wires are brought to the sidewalk line and enter the building basement.

In several prominent places high tension electrical apparatus is installed by Mutual Outfit, where it is within reach of anybody and where not even a sign is placed notifying the public that the potential being carried by the wires and bare parts is up in the thousands and "Hands Off."

Installed in the basement of Lucke's Shoe Store on Market Street, for instance, are several arc cutout switches; these have had, for some reason not known to the writer, their covers removed, thereby exposing the metal current carrying parts for the inspection of the buzz-saw boy. These switches, carrying as they are, a current of several thousand volts, would without a doubt electrocute anyone touching same.

The same condition of affairs, or worse, exists at Summerfield & Roman's, clothiers, Fifth and Market Streets; Johnson's Restaurant, History Building, basement, gore corner of Geary and Market Streets, and several other places. This condition of affairs should be looked into as it is criminal to allow them to exist.

Consumers of electrical current looking for cheap service can find it readily enough, if they assume all risks to life and property that the methods of these experts in Timber physics, and in other things legislative, municipal and judicial, will give them, free of extra compensation. Applications for this kind of cheap service may be made to philanthropist Alvinza Haywood, Esq., care of the People's Anti-Monopoly Low-Price Waterworks Company, Oakland, or to his fellow-discoverer, also a pure philanthropist in his own right, Mr. Barry Cornwall, care of the Coal Combine, U. S. Appraisers Building, or to James

DESIGN FOR STONE BUILDING.
ALBERT SUTTON, Architect.

Fisher, Esq., Secretary of the Mutual Electric Light Company, limited—only as to time of existence.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

RESIDENCE for Mr. F. W. Voogt, Alameda, Cal., B. E. Remmel, Architect.

DESIGN for a stone Building, Albert Sutton, Architect.

THE USE OF STONE IN SKELETON CONSTRUCTION.

E. MCL. LONG, C. E., IN STONE.

A STONE wall is a rigid mass of solid stone and cement from face to back, and is as durable as the foundation on which it rests. Through all ages it has been a symbol of strength, and represents stability and solidity.

All massive structures, and those designed to stand through centuries have been built of stone, or stone and cement, with no other material entering into their construction; and in viewing an edifice of this character, whatever may be its architectural rendering, one cannot be impressed with its appearance of strength. The walls sustain the weight of the building, and are thick, with small openings for doors and windows, thus showing to all observers their ability to do the work for which they are designed.

We have become so accustomed to looking upon stone, when used in the walls of buildings, as the strength-giving material of the structure, that it is rather hard for us to consider it otherwise. It is, therefore, that the architect in applying a covering of stone to a structural steel frame endeavors to create the impression that the building owes its stability to this covering. This hallucination has been partly produced by constructing heavy basement walls and reducing the size of windows to a minimum and giving them deep reveals. While this form of construction may be pleasing to the eye, as we are now trained to look at stone work, it is a fraud and is certainly very undesirable, from an economic standpoint, for stone work is expensive and every extra pound causes an increase in size of beams and columns, and from a practical standpoint since the most desirable thing in an office or store room is to have a maximum amoudt of light. In most instances, however, where light rooms and economy are the prime objects of the designer, the stone is applied so as to produce very queer results. Where the ground floor of a high building is used as a store, the windows and doors occupy nearly all the wall space and we see twenty stories of masonry supported by stone piers scarcely sufficient in size to support their own weight, and stone beams or flat arches three feet deep carrying a superimposed load of hundreds of tons over a span of twenty feet. We can hardly, however, class this as an architectural fraud, for it is self-evident that the stone is not doing the work as represented.

However applied, stone has become very popular, at least, as a covering for the fronts of steel constructed buildings, and while it plays no part in the structural strength of the building, it still has its own duties to perform in affording a protection against the weather both for the interior of the building and for the steel work. So, from the top of the beam at one floor level to the bottom of the one above, it is a stone wall, and as such acts an honest part, and it is an error to say that a steel skeleton is covered with a veneering of stone, for the stone is a necessary part of the structure, and the completed wall is a combination of stone and steel in which each material has its duty to perform.

During the period when the steel skeleton constructed building was first being brought into use, the question was often asked whether two materials, of such different physical natures as stone and steel, could be joined together to form a solid whole. The question has been well answered by the number of examples we have, in none of which have the different rates of expansion and contraction damaged a building. This difference is not as great as most people would suppose. For a rise of 100° in temperature, steel expands one-eight of an inch in sixteen feet. For the same rise in temperature, granite expands one-eight of an inch in twenty feet, and marble one-eight of an inch in eighteen feet. According to these figures, since the stone is exposed to the extremes of temperature and the steel is protected, we might infer that the stone expands or contracts more than the steel. However this may be, since no practical inconvenience is produced, we will let the question drop, and confine out attention to methods of building the masonry to the steel.

The typical steel skeleton building is one in which the frame of steel is designed to carry all permanent and temporary loads and convey such loads through its columns to

the column foundations, and among the permanent loads is included the weight of the walls. The walls rest on beams, commonly called spandrel beams, at each floor level, and thus each wall is the height of one story and has only its own weight to sustain, whether it incloses the first or twentieth floor rooms.

The problem that presents itself to the architect is to construct a wall to fill up a rectangular opening in the side of a building. As a foundation for this wall he has a steel beam, or a combination of beams, to limit its height; he again has beams similar to the foundation beams, and to limit its extent laterally he has steel columns. The foundation beams are designed to carry the weight of the superimposed wall with a minimum amount of deflection and the wall must be designed to be as light as is consistant with strength and its efficiency as a protector against the weather. It is better that this wall should be entirely of stone than of brick with a stone facing.

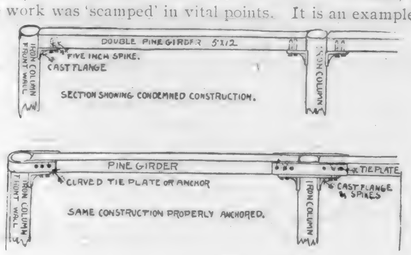
As steel buildings are at present constructed, another condition to be fulfilled is that all beams and columns must be protected against the weather. This will necessitate the outside of the beams and columns being at least 8" within the building line.

To be Continued.

SLOW-BURNING CONSTRUCTION.

THE AYER building in Wabash avenue in this city which, on the 16th inst., collapsed in less than ten minutes after the fire started was a so-called "mill-construction" building. The awful catastrophe demonstrated it to have been nothing but a fire and death trap of the most dangerous description.

It was a large area building, seven stories high, 80 feet wide and 160 feet deep. The front was entirely constructed of iron and glass. It was built in 1890 at a cost of $112,000. The original owner says he gave the architect carte blanche for a substantial mill-constructed building, and that when it was finished it was so well liked by the insurance people that he secured a "very advantageous rate for it." If that is true then the architect has a terrible responsibility hanging over his head. Ten persons lost their lives and a score or more were severely injured, say nothing of the loss of $750,000 worth of property. One of the city building inspectors made an examination of the ruins after the fire and he is reported as saying: "This was not a cheap building. Plenty of first-class materials appear to have been used, but the work was 'scamped' in vital points. It is an example of



pure carelessness on somebody's part, as the cost of doing properly what was neglected in this case would not have exceeded $200 for the whole building."

As to the construction of the building Deputy Commissioner Shea of the building department in his testimony said: "I found the columns with a 1½ in. cast iron flange to receive the wooden girders, and said girders were fastened with two five inch by one-half inch wrought iron spikes (see first diagram). No iron straps around the columns connected with the girders, as there should have been (see second diagram.) I also found the interior girders fastened to columns in the same manner, with an iron strap twenty-four inches long and two inches wide by one-half inch thick, with nail holes in the end of each strap. These straps were fastened to the side of each girder by three-inch by one-quarter-inch spikes. The iron anchors of the north and south walls project about six inches outside of the walls, with two nail holes in the ends. The building was of mill construction. The joists were about nine and a half feet long, four feet apart. Joists were six by twelve inches. The length of girders about sixteen feet, made of two pieces bolted together.

In the same City on the Tuesday following the collapse o the Ayer building, the Shoeneman, another "mill construction" affair, became a total loss by fire, the immediate cause being the explosion of a gasoline can. This building was seven stories in height and the whole inside fell to the cellar in a remarkably short space of time.

If these buildings had in fact been mill-construction they would not have burned as they did. Everybody who knows anything about mill-constructed buildings knows that they are so built to be slow burning. That is what they are built for, and that is why the insurance companies make a lower rate on them than they do on buildings of ordinary construction. But from the frequent and disastrous fires in the last year in so-called fire-proof and mill-constructed buildings, it begins to look as if they were the worst kind of fire-traps, and built solely to deceive the insurance companies. It is about time for the companies to look into the matter. They owe it to themselves and to the public. It will not do to depend upon the city building departments. They cannot be depended on. That has been demonstrated in the Ayer building.—*The Investigator of March 26.*

[NOTE—The Shoeneman stood between the old Colony building, seventeen stories high, on one side, and the Manhattan building, sixteen stories high on the other. Both of these sky-scrapers were of the steel skeleton construction and neither one of these buildings was much endangered by the fierce heat.—[EDITOR.

SOUTHERN UNION STATION AT BOSTON.

A RAILWAY passenger station that in size and equipment will be without equal in the United States, perhaps unequaled anywhere in the world, is now in the course of construction at Cove and Summer streets and Dorchester avenue, Boston. The total investment of the Boston Terminal company, which has conceived this project, will amount to nearly $12,000,000. Four million dollars will be expended in construction, the contract price of the main station building alone being $1,100,000. As a whole, the station was designed by George B. Francis, engineer of the Boston Terminal company, assisted by the chief engineers of the roads that will ultimately use the station.

The design involves a unique feature in station construction. In the first attempt to introduce into one terminal an electric suburban service, and the regular through passenger traffic of a steam railway. The difference in character of the suburban or commutation passenger traffic and the passenger traffic which goes beyond the commutation points

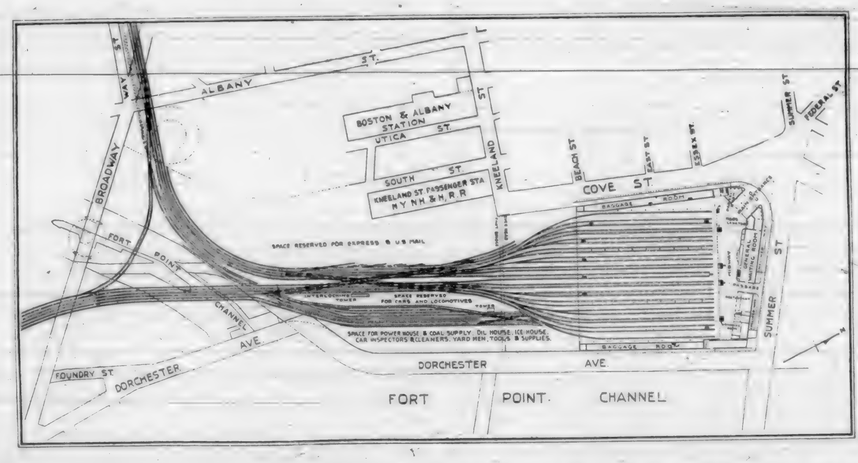
has long been recognized, but the system of handling the former by means of a subway was never successfully projected up to this time. It is the design to handle the traffic of the southern union station upon two floor levels. In the subway two loop tracts with ample platforms will accommodate the entire electric suburban service, while the upper floor will provide for the steam passenger service, with 28 stub tracks capable of holding 350 passenger cars.

The main entrance to the station will be at the corner of Sumner and Cove streets, where it is built on the arc of a circle for a distance of 228 feet. On either side of the curved portion the main building extends 320 feet on Sumner street and the same distance on Cove street, with a further extension of 350 feet on the latter thoroughfare for baggage-rooms. The general waiting-room on the first floor will extend through two stories, and has an area of 65x225 feet.

A general idea of the size of the station may be obtained from the fact that the main and connected buildings have a roof area of 700x650 feet, the largest railway roof in the world. The structures will require about 15,000 tons of steel and will rest upon 40,000 spruce piles. The architects for the building are Messrs. Shepley, Rutan & Coolidge.

The first story and basement are devoted entirely to railroad purposes, the second story to offices of the terminal company and general offices, with restaurant rooms in addition to those provided on the first story. The third, fourth and fifth stories will be occupied by the offices of the several railroad corporations forming the terminal company.

The suburban station in the subway, accessible by either inclines or steps, is below the level of the ocean, which is but one hundred feet away. This necessitates the use of about eight acres of waterproofing material to shut out the water effectually. Above this is placed an average of 3½ feet of concrete to resist the water pressure.



At this time seven-eights of the work on the new station is under contract, and about one third of the construction has been accomplished. Norcross Brothers of Worcester Mass., are the contractors for the foundations and buildings, excepting the steel work for the train shed and the bridging over the suburban tracts, which is let to the Pennsylvania Steel company. About $250,000 is being spent on construction monthly.—*Construction News.*

ELECTRICITY IN MODERN BUILDINGS.

IN THE construction of a certain class of building a steel framework, filled in with stone or other material, is being very largely used, and as electricity is rapidly becoming the means of distributing light and power, and to some extent, even heat, throughout the halls, corridors, offices, etc., of any building which proposes to offer all the best modern conveniences, it may be worth while to consider whether there will take place any interaction between the steel frame work, considered as a conducting network of comparatively low resistance, and the electric circuits which distribute the lighting and power current. It is, of course, evident that such a steel framework will offer a path of comparatively low resistance to any current that may be set up in it, and it is the purpose of this article to formulate those conditions which will tend to the setting up of such currents, and their fiscal effect on the building materials.

Suppose, says a clever writer on matters electric, we have a steel frame building with a complete system of electric distribution—for lighting, elevators, heaters, etc., etc.—it can easily be imagined that there may be set up inductively a most complicated and interlined system of active currents in the various uprights and horizontals forming the frame, and that they may be of quite considerable magnitude. This can occur not only in the steel frame itself, but in the piping for the heating or auxiliary gas lighting services. With a direct current distribution for lighting only, these induced currents would probably have a negligible effect, as it is only at the moment of make and break that inductive action would take place, although even in such a case a direct current, though continuous in direction, will have sufficiently small fluctuations in strength (owing to the fact that the number of coils in the armature is not infinity) to keep up a continual alternating current in all the pipes and beams parallel to it and within the sphere of its influence. But in very many cases current is distributed for elevator and motor purposes, and here we find not only the small fluctuations due (as mentioned above) to the armature construction, but also that fluctuation due to the varying demands of the elevator and motor services, which, while not so rapid, will have an enormously greater amplitude, and so a much greater inductive influence. There are very many buildings, moreover, that employ an alternating current for lighting, the influence of which requires no pointing out. So that it appears that there will always be some circuits induced in such buildings, whether in the frame or the piping.

It is well known that an electric current flowing in a circuit must produce one effect and may produce more. It must heat the conductor and may decompose it. The heat generated in the conductor depends on the amount of current flowing, and on the resistance offered to it, and in a circuit of varying conductivity the greatest heat will be generated at the point of greatest resistance. In a circuit—again taking from the supposable case of the same writer—composed of beams and points of function will be those of highest resistance, and will therefore be the heating points.

Just how far the expansion and contraction due to heating and cooling may be expected to work with the natural vibration to loosen the joints, is a matter that affords a very interesting field for discussion and experiment. But if it be granted that it does have the effect of so loosening them, then such loosening will tend to promote the decomposing action of the current flowing, with the assistance of whatever slight amount of moisture has condensed out of the atmosphere (or elsewhere) on the opposing faces of the loose joint. This latter action of the current is probably of greater importance than the former, as its tendency is to loosen by decomposition, and just where the utmost rigidity and permanence is desired, viz., in the foundations. The electrolytic injury would take place just at the base of a steel pillar, where the current was able to escape to earth, and the effect would be to eat away the metal, as the iron of water pipes is eaten away by the passage of railway currents. The electrolysis of gas and water pipes might be even a serious matter unless precautions be taken to minimize its effect.

While it seems impossible to so arrange as that there shall be no induced currents in framework or piping, still it is possible, and in most cases would be well, to adopt such precautions as will confine them within such small limits that they may become negligible. It would be well to thoroughly ground the entire steel structure by copper wires of large section leading from various points to the earth, and making good contact there with permanently moist soil. It would also be advisable in laying out circuits to so arrange that all those wires carrying the main current shall be as far removed as possible from any part of the structure, and as close together as insurance regulations will permit. If it be necessary for the main wires to be close to a pipe or pillar, and to run parallel to it, then they should be placed one on each side of it so as to neutralize each other's effect.

BOOKS AND PERIODICALS.

THE BROCHURE prints each year over one hundred half-tone engravings from photographs of European architecture, the subjects being carefully chosen, is those likely to be of most value and interest to architects and draughtsmen. Each issue deals with some particular building or class of subjects; the October issue for instance, illustrated in detail the Great Staircase of the Chateau of Blois; the December issue contained photographs of beautiful Italian holy-water fonts; the January number illustrated Sicilian churches.

It will be evident that such pictures are of great value, not alone to architects and draughtsmen and students of art, for whom they are primarily intended, but also to all those to whom the best of the world's architecture appeals. An article of detailed description and comment accompanies each set of illustrations.

Although these photographs and the description of them form the chief features of the magazine they by no means constitute its entire contents. Articles of various kinds are constantly published which interest all who in any way have to deal with architecture. It is a marvel that the magazine can be sold for the subscription price—50 cents a year.

CARRICK'S FIRE-PROOF CONSTRUCTION.

THIS fire-proof system is the invention of a practical plasterer and will remedy many defects and difficulties from which other systems suffer. The obect of this invention is to provide for the construction of complete floors, ceilings, partitions, columns, etc., in which a space is provided for ventilation, making the introduction of pipes and electric light and bell wires a very easy matter. The air space is accessible and wires may be easily run through or removed for repairs.

Partitions constructed of channel iron studding, set at every sixteen centers, bolted and fastened at top and bottom, and with transverse stiffening braces and sheet steel lath fastened thereto columns incased in the same way, ceilings formed with sheet steel lathing secured to angle iron bars, extending beneath the floor beams, and knees or brackets to which they are fastened, said knees being bolted to iron bands, which extend around the I beam, at every sixteen centers.

The concrete flooring to be supported by angle irons and knees or brackets as above, extensions of sheet steel upwards from the angle irons every thirty-two inches, said extensions riveted to the angle irons and having 2x2 inch wooden strips, nailed to the upper edge transversly for the wood floor to rest upon and from a space between floors and concrete for ventilation, piping and wiring purposes.

The sheet steel extensions also divide the concrete at their upper edges into panels, to prevent cracking in case of vibration, contraction and expansion. The lathing is made in sections or sheets, which are preferably made of galvanized sheet steel and by means of dies properly formed, these sheets are stamped with slots or channels, the portion which forms the slot is so cut that it turns inwardly and forms a key or lock to hold the plastering in place on the interior of the lath and also a ledge or support to prevent the plaster which protrudes inwardly, from falling down as is generally the case.

Carrick's lath construction is especially valuable for plastering on brick walls, as it does away with the necessity for plugging and furring, thus saving time and expense.

The sections are attached to the wall by means of large nails driven into the brick joints, while the supporting V shape rib, acts as a furring strip. It should be understood that the system takes in the plastering work as well as the fire-proofing.

The inventor claims the following points of superiority: 1—Simplicity and rapidity in construction. 2—Absolute prevention of cracking or bulging. 3—Easily and quickly repaired. 4—A splendid sound deadener. 5—Fire, water and vermin proof. 6—Gives perfect ventilation, making it especially valuable for use in large buildings.

THE BEST FIREPROOF CONSTRUCTION FOR BUILDINGS OCCUPIED FOR MERCANTILE PURPOSES.

PAPER READ BY W. L. B. JENNEY BEFORE THE FIRE UNDERWRITERS' ASSOCIATION OF THE NORTHWEST.

CONTINUED FROM LAST ISSUE.

WE now reach the question under discussion: "What is the best fireproof Construction for Buildings occupied for Mercantile Purposes." As recommended in the Appraisers' Report (Insurance World, July 1, 1897), "the first requisite is a good foundation," which in Chicago means that the loads shall be uniformly distributed, that is to say, the load upon each footing shall be carefully calculated taking into account the weight of the building and the load within, that is, all the load that will come upon said footing. Then make the size of the footings so that the load per sq. ft. shall be the same in every instance throughout the building. This load should not exceed

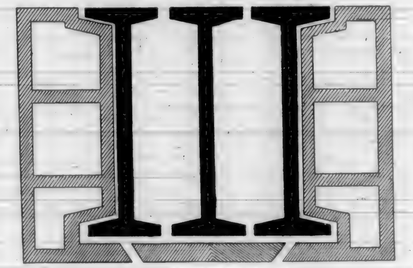


Fig. 2.

3,500 lbs. per sq. ft., for should this load be much in excess the settlement will be so great as to be inconvenient, and moreover continue too long, besides it increases the difficulty of obtaining an absolutely uniform settlement. With the load designated the total settlement should not exceed three inches, and should cease entirely by the end of the first year after the building is fully occupied. Any unequal settlement is not only a disfigurement to the building, but it causes a movement in the fireproofing that may be equal to a disarrangement, loosening the flange protection of the beams and girders so that they will fly off as soon as touched by a stream of water.

Second, fireproofing. This should be much more substantial than what is at present in general use. The recent fires have demonstrated that it is not difficult to protect the steel from injury. The fireproofing as usually constructed protects the steel, but is itself usually destroyed, causing serious loss. The material should be carefully tested by heating to redness and plunging into water, repeating this test five or six times. If it flies to pieces it is worthless. What is known as soft porous terra cotta, if the clay is good, usually stands well. This is manufactured by adding six parts of saw dust to four parts of fire clay. On burning, the saw dust is consumed, and furnishes a tile full of air holes or little cells, rendering it impossible for any hurtful heat to penetrate to the metal. The weakest part in the usual fireproofing is the protection of the soffits of the beams and girders. As usually constructed they are like Fig. 2, a long, weak flange on either side holding in a dove-tailed manner the soffit tile. The tile are also too thin and too close to the flanges of the metal beam. This is a serious fault, because the soffit is the very surface which has to resist the intense heat and action of the fire from the burning goods below, and is exposed to the direct force of the water.

In the *Clay Worker* of April 18, 1897, I find in the report of the proceedings of the last convention of the brick manufacturers at Buffalo, N. Y., a discussion of this subject. Mr. Gates, president of the American Terra Cotta Co. of Chicago, condemns the arrangement of Fig. 2, where the suffit tile

only 1 inch thick is placed close to the flanges of the beams, and only supported by the long weak flanges of the side tile. Mr. James Taylor, Fig. 3, made a diagram of a method he suggested which would overcome the dangerous method of Fig. 2—so justly condemned by Mr. Gates. He proposes a porous terra cotta flange 2 inches thick, Fig. 3, supported

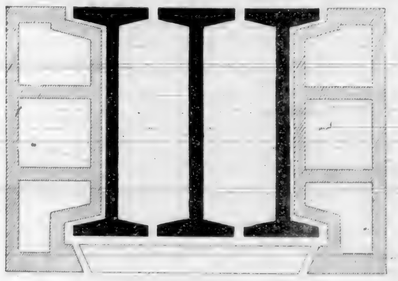

Fig. 3.

by short strong flanges on either side. By this method the whole surface of the metal girder is covered with a non-conducting material which has [illegible] to crack or break under the most [illegible] difference of temperature. The short flanges on either side reduce the liability of cracking or breaking to a minimum, and the additional thickness affords additional solidity without much increase of weight, and greater ability to resist the action of heat and water. In Fig. 4, Mr. Gates showed how the terra cotta could be

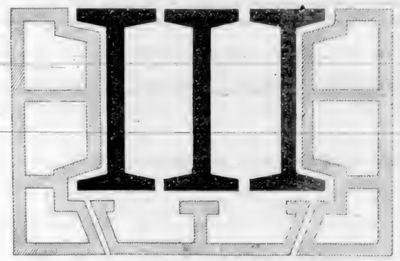

Fig. 4.

used in a double capacity, as a fireproofing protection and as an exterior finish when such girders are used projecting from exterior walls—mouldings can be added at pleasure. Care must be taken in dimensions and shapes in order that the side flanges shall securely hold the soffit tile so that it cannot escape or be knocked out by a stream of water. The floor arches should be very substantial, and what is known as "porous and end construction" is recommended. The laying of the terra cotta is very essential. Common lime mortar should be discarded as unfit for the purpose and Portland cement mortar should be used, adding only sufficient lime mortar to make it work freely under the trowel. Every joint should be filled with mortar over the entire surface and the tile crowded close together. In putting in the key, unless it fits closely, slabs of tile covered by cement mortar should be forced into the joints. It is very essential that these tile floors should be very rigid, as by so doing they prevent the lateral movement of the building not only in case of fire but as against high winds. If this work is well done they will take up a material portion of the wind pressure even in a building of moderate dimensions. In most of the fires that have occurred in fireproof buildings very serious damage has been done to the floor arches by scaling off of the lower webb, necessitating the replacing of the floors at an expense even greater than first cost. Concrete on top of the floor arches should be of good quality. Soft coal cinders should not be used. Crushed slag of the blast furnace is far better; it is full of air cells, and being produced at very high temperature is not affected by any heat likely to obtain. This concrete should not be inferior to that used in sidewalks, and when practicable should form the floor so as to avoid wood floors. The column protection is another detail that should receive the most careful attention, for the columns are the main supports of all that are above, and if a single one should fall it brings down all there is directly above it, and the loss is necessarily very serious.

At the Fair building the columns are doubly protected, see Fig. 5, so that should the outer layer of terra cotta be

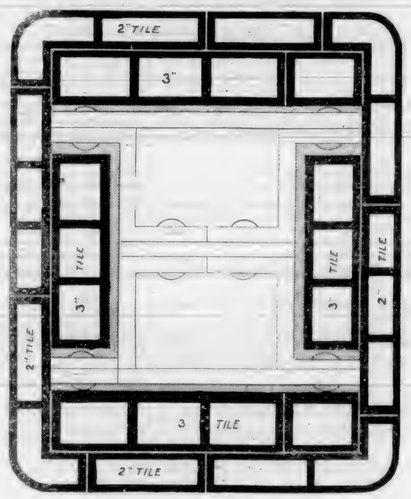

Fig. 5.

knocked off the column would be sufficiently protected by the second layer, which would be sufficient to resist the heat and prevent any serious injury to the column. For round columns there can easily be two layers; the inner one should be bound on firmly by wires or wire netting, which, lying close against the terra cotta, is itself protected. That this is the case can easily be shown by tying a piece of sewing cotton tight around a lead bullet and holding it in the flame of a candle; the lead will melt before the string burns off. The Chicago city ordinances demand in case of buildings devoted to the sale, storage or manufacture of merchandise, the covering of columns shall be of brick not less than 8 inches thick; if of hollow tile these coverings shall be in two consecutive layers each not less than 2½ inches thick; if of porous terra cotta it shall consist of at least two layers, each not less than two inches thick, each course breaking joints and to be so anchored and bonded in itself as to form an independent and staple structure. If this is carried out in a proper manner the protection is all that is necessary.

To be continued.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

See a full size working model at our store.

Plans and Specifications Invited for an Hospital Building.

Public notice is hereby given to architects that competitive plans and specifications for the erection of an hospital building will be received by the Board of Supervisors on MONDAY AFTERNOON, September 12, 1898.

The proposed building to be of modern design and to be constructed of stone or brick, or of both, with all the latest scientific improvements.

The said hospital building to be erected on the lot of land commencing at the most southeasterly corner of a tract of land known as and designated, on the official map of the city and county of San Francisco, as the "Almshouse tract."

The said plans and specifications to be so prepared that the cost of the building shall not exceed in the aggregate the sum of three hundred thousand ($300,000) dollars.

The architect whose plans are adopted will be appointed architect and superintendent of the building, and will be required to give a good and satisfactory bond to insure the completion and construction of the said building for the amount of the cost as made by the said architect. The architects submitting plans determined by the Board to be second, third and fourth in merit will receive premiums of $1000, $750 and $500 respectively, with the understanding that any features of said plans and specifications which may be considered useful or necessary to be embodied in the plans adopted may be used without further cost of charge.

JNO. A. RUSSELL, Clerk.

411 MISSION ST., Bet. 1st and Fremont, SAN FRANCISCO, CAL.

BEST FOR WARM CLIMATES

Cannot Crack or Peel as Pain Does.

Being *in* the wood, and not wholly on the surface, like paint.

CABOT'S CREOSOTE SHINGLE STAINS

wear better and longer in warm climates than paint, which cracks and peels off under the hot suns. They are the only exterior colorings that do not turn black, and the only treatment that will prevent the blackening of Redwood. No other Stains can contain Creosote, "the best wood preservative known," our patent giving us the sole right to make, sell or advertise Creosote Stains.

The *Siding* of the Kip Mission, above, is Creosote Stained.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

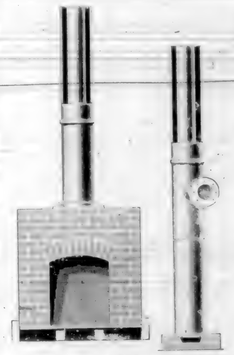
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET, SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

Sacramento and Larkin. Brick work, carpentry etc, for five flats and two stores; o. Mrs. F. de Lariviere per J. S. Perini, attorney; signed, May 14; filed, May 3; cost $7300. Plumbing, gas fitting, sewerage, etc; c. E. Kraus; cost $1200. Painting, graining, etc; c. G. A. Petterson; cost $625.

Scott near Geary. Repairs to Girl's High School; o. Board of Education of S. F.; a. T. J. Welsh; c. Daniel Sherrin & Sons; cost $1600.

Second and Mission. Plumbing work, etc; o. Wells Fargo & Co; a. Percy & Hamilton; c. W. F. Wilson; signed, April 15; filed, April 18; cost $16,856. Elevator work; c. Fraser Electric Elevator Co; signed, April 13; filed, April 18; cost $15,500.

Second and Mission. Marble work, etc; o, Wells, Fargo & Co; a, Percy & Hamilton; c, Duffey Bros; signed, April 9; filed, April 18; cost $25,000.

Shipley near 6th. Alterations and additions; o. Gus. Harshall; a. Salfield & Kohlberg; c. J. V. Hull; signed and filed, May 12; cost $3185.

Sixth Ave. near California. To build; o. Felix Marcuse; c. Marcuse & Remmel; signed and filed, April 29; cost $8000.

Stenart near Mission. Excavations, etc, for 3-story brick; o. John F. Boyd; a. McDougall Bros; c. H. Stettin; signed and filed, May 6; cost $7680.

Sutter near Mason. Electric elevator; o. Maude L. Bertschman and Blanch B. Morton; a. Oscar Haupt; c. W. L. Holman; cost $1625.

Turk near Taylor. Alterations and additions; o. James D. Phelan; a. Curlett & McCaw; c. A. H. Willcim; signed, April 18; filed, April 19; cost $6173.

Twelfth Ave. near Clement. To build; owner and contractor, D. Taylor; cost $2000.

Washington near Mason. Demolitions, and all work except mantels and gas fixtures; o. L. Brizzolara; a. E. Depierre; c. P. A. Antonelli; signed, April 18; filed, April 19; cost $3900.

Washington near Spruce. Two-story frame; o. Dr. J. Mora Moss; a. Sam'l Newsom and F. H. Myer; c. Depew & Brooks; signed, May 14; filed, May 16; cost $2750.

Webster near Post. To build; o. Mrs. Dora Dteckler; a. W. J. Cuthbertson; c. D. Currie; signed, April 22; filed, May 4; cost $1480.

The Yale and Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," they are intended to meet the condition where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

GENERAL OFFICES:

Nos. 9, 11 and 13 Murray Street, New York City.

BUILDING NEWS.

ALAMEDA

Santa Clara Ave, near Lafayette. To build; o, Cullen Bryant; a, A. Sutton; c, Z. O. Field; signed, April 25; filed, April 26; cost $6298. Plumbing and heating apparatus; c, Dalziel & Moller; signed, April 25; filed, April 27; cost $994.

ARIZONA

John Ivancovich contemplates erecting a brick building with stone foundation, adjoining the A. O. U. W. hall, at Tucson. It will be 75x85 feet, with iron and plate glass front.

ANAHEIM

N. B. Mitchell of Pasadena is reported as having plans for a hotel building which he is contemplating building upon his property here.

A High school will be the next enterprise to be started in Anaheim. The people have grown tired of sending their boys and girls to Santa Ana and Fullerton.

AZUSA

Six buildings were burned here last week, involving a loss of $10,000.

BANNING

Mr. M. L. Bridges is expected soon from Los Angeles to build the foundations for the new residence of Charles M. Morris, and to complete the work of plastering, etc., on the new cottage being built for Dr. King.

FRUITVALE

Spring Tract. Cottage; o, Elizabeth L. Murison; a, M. G. Bugbee; c, A. C. Soule; signed May 5; filed, May 5; cost $1580.

BUILDING NEWS.

EL MONTE

Architects Smith & Elder have prepared plans for a frame store building 30x70 feet, for E. J. Dobson, to be built at El Monte. The same architect has plans for a cottage for George Slack, to be built at the same place, by day's work.

OAKLAND

Eleventh and 6th Ave. Alterations and additions; o, C. H. King; a, W. J. Mathews; c, C. Christensen; signed, May 5; filed, May 6; cost $1400.

Webster street, No. 1576. Alterations and additions o, Ann M. Laidlaw; a, W. M. Campell; c, F. Eskilson signed, April 2; filed, April 26; cost $1135.

Hillside Ave. To build; o, J. H. and Julia L. Borrowlough; a, D. E. Oliver; c, H. E. Wharton; signed and filed, April 6; cost $9257.

Myrtle near 12th. To build; o, Adolph Uhl; a, A. W. Smith; c, W. E. and J. C. S. Whalin; signed April 4; filed, April 19; cost $9200.

Eleventh and 6th Ave. Alterations and additions; o, Harriett A. Braun; a, M. G. Bugbee; c, A. C. Soule; signed, May 5; filed, May 7; cost $800.

CLAREMONT

As a result of raising $62,000, since January, Dr. Piersons of Chicago gives $20,000 for a science hall for Pomona college. The hall is to be 60x90 feet, will face Holmes hall on Warren avenue. There will be three floors: the lower floor given to mathematics the second to biology and the third to chemistry and physics. Steps are being taken which will result also in the erection and equipment of a gymnasium.

RIVERSIDE

The supervisors of Riverside county have decided to erect the hospital building, to take the place of the

BUILDING NEWS.

one burned, on the old site at San Jacinto, and will call for bids as soon as matters can be adjusted. The building is to be completed by July 1.

The county clerk has been instructed to advertise for bids for supplying the county with suitable lands and buildings for county hospital purposes to take the place of the building destroyed by fire.

Work on the new passenger depot is progressing. The outer walls are of pressed brick and present a very pleasing effect. The building will cost when completed $10,000.

PASADENA

It is reported that a Mr. Neumeister, formerly of Chicago, will erect an ice plant here.

Work on Hotel Green annex goes steadily on. The decorative architecture begins to show up splendidly.

Ellis Hakes, of Illinois, has purchased a fine building site near the La Pintoresca. He contemplates erecting a home on the property shortly.

Architects Locke & Munsell are preparing plans for the remodeling of the Raymond residence, on Columbia street, Pasadena, which has been purchased by C. W. Smith, president of the Los Angeles and Pasadena Electric Company. The same architects have been instructed by E. S. Chamberlain of Des Moines, Iowa, who is charmed with the Southern California style of architecture, to prepare plans for a handsome brick and stone residence to be erected in that city.

Architect C. W. Buchanan is preparing plans for a nine-room modern residence for D. A. Davis, to be erected on North Moline avenue.

VOLUME XIX. MAY 20th, 1898. NUMBER 5.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

ARCHITECTS will examine with interest the illustrations of tile arch construction in the hightest office building in the world, which are shown on another page of this issue.

The *Engineering News*, to whom we are indebted for the article, has further information that similar defects can be seen in the tile floor construction of several buildings now going up in New York City.

That paper in its editorial comments on existing methods of building inspection, emphasizes the fact that competent authority has assured the Editor that these are merely ordinary examples of tile floor construction, such as can be found in odd corners around any first-class fire-proof building in that city.

As to tests and the extravagent claims which have characterized tile floor manufacturers' statements, the *News* pays its respects very neatly in the following paragraph:

"Suppose we accept this view of the case, that tile construction of this sort is common, or at least frequent in fire-proof buildings. If this be true, then it follows that our knowledge of the strength of such floors is to say the least very imperfect; for all the tests which have been made of the strength of such floors have been made on arches carefully constructed, with sound and symmetrical blocks, properly bonded with mortar. That such construction as is shown in our photographs is far weaker than floors built like the test arches, no one would think of denying. Perhaps it is still strong enough for safety; that is a matter which we shall not attempt to decide; the point of importance is that tile floor arches are just as capable of being built in a careless and defective manner, not contemplated by their design, as any other sort of engineering construction; and in view of some of the extravagent claims which have been made for tile floors, we believe, is well worth establishing."

FIRE-PROOF BUILDINGS AND LOW INSURANCE RATES.

800 BUILDINGS OF THIS CHARACTER IN NEW YORK CITY VALUED IN THE AGGREGATE AT NEARLY $200,000,000.

THAT is termed a fire-proof structure is very different from the so-called fire-proof building of twenty years ago. While it is still true that the absolutely fire-proof building scarcely exists, the modern steel-framed building constructed throughout of inconbustible materials is practieally fire-proof. This statement is supported by the test of several fires, and by remarkable concessions in rates by fire underwriters.

Salvage on the fire-proof buildings themselves has always been exceedingly large, the walls and steel framework being only slightly damaged in the fiercest fire, and scarcely entitled to a claim for loss as the result of any ordinary blaze. This can not always be said, however, of the combustible contents; for a degree of heat and amount of water not seriously affecting the building may destroy goods and furniture.

Fire underwriters have carefully studied the risk of the modern fire-proof building. They have employed experts and have accumulated statistics to determine the character of the new risk from their point of view; and they are now satisfied it is a safe risk.

Competition for fire-proof risks has recently been very keen among New York underwriters. This is partly due, it is true, to the recent suspension of rates in the Metropolitan district; but it is mainly due to the fact that the underwriters believe that large losses need not be feared among so-called fire-proof buildings. Rates have been amazingly low. We submit a few examples:

Lord's Court was written at five cents for three years. The Central National Bank building and the fire-proof Arnold. Constable building were written at ten cents for five years. Large lines are carried. On one thirty-two storied steel skeleton building classed as one of the several hundred New York fire-proofs, nine companies wrote $675,000 in sums ranging from $50,000 to $200.000. The total premium for five years was only $675, and it is understood that the broker who placed the risk got twenty-five per cent of this small sum.

The underwriters are not gambling. There are about 800 fire-proof buildings in New York City, valued in the aggregate at nearly $200,000,000. At an average rate of fifteen cents for five years this fire-proof business would produce $300,000 in premiums. As the total destruction of any of these buildings is impossible, the damages to a large number of them could hardly be severe enough to wipe out all profit even at this low premium rate. We may therefore assume as a fact that low rates will continue to be the rule on these superior risks, even after a new rating by a tariff association.

This low rate experience in New York supports one of the strongest arguments urged by architects and builders in behalf of first-class buildings. The difference in insurance rates justifies the construction of first-class buildings of the modern fire-proof type.

AN EXPLANATION THAT EXPLAINS.

OR HOW TO EFFECT PROGRESS EITHER FORWARD OR BACKWARD.

IT IS NOW an open question in building circles as to which building will be first completed and opened for the use of a patient and long suffering public. The Hall of Justice or the new Post-Office. With the former the contractors have been somewhat given to experiments in vast fields of enterprising development of new industries—such as opening up stone quarries and establishing brick yards, in out of the way nooks only known to themselves. These enterprises while laudable and in every way worthy of commendation, take much time and money. Of the former, the now famous firm of brothers, possess or at least act as if they were posessed, of unlimited quantities; of the latter, if dame rumor is to be believed, the Harbor Commissioners have awarded them liberal portions for their now practically completed work on the Ferry Depot.

It is just possible, however, that their supply of the former will be curtailed. More certain things than their grip on continuous extensions have "gang'd aft aglee." The term of office of indulgent supervisors, for instance, will expire one of these days. Then what?

The stone quarry riddle has been eliminated from the case by the firm position taken by the architects—Messrs. Shea & Shea—in standing by their specifications and Colusa stone—now all in place.

The expanded metal people too are about out of the way, having completed the first three stories and are now well on with the fourth.

The brick—just plain ordinary pressed brick, ah! there's the rub—can the contractors plead successfully to the powers that be that they are up against a pressed brick combine, then by working up the old, old story, of self preservation being the first law of nature, gain time enough from this board and the next, to bring to a conclusion this last new enterprise of theirs, viz:—The pressed brick works they are said to have established at Stockton.

This about disposes of the Hall of Justice, and it gives much "the best of it" to the New Post Office building's chances, now under pretty fair headway. The daily papers may retard progress somewhat, in their efforts to assist the marble quarry men for the revenue there is in it. But this is doubtful; and the money could be far better expended at some of the unopened marble quarries in the State. In that quarter there would be a possibility of seeing the color of it again. As things stand now, a lobby at Washington with log rolling tendencies; many small but beautiful exhibits of speculative marble possibilities; with the purchased surport of the said daily newspapers, constituted about all the stock in trade that has been thus far brought forward to inkuce the Treasury Department officials, to seriously consider California marble as a structural possibility.

The Supervising Architects office at Washington has kept the local superintendent, Mr. Roberts, quite busy, for some time back, visiting stone quarries, marble quarries and marble locations. This is all right and should be quite satisfactory to all concerned; but, and what a large but that is, there will be no delay from this time forth, and what is more, the department ruled a long time ago, that "the opening up and development of quarries, had no part in the functions of Government.

THE USE OF STONE IN SKELETON CONSTRUCTION.

E. MCL. LONG IN STONE.

CONTINUED FROM APRIL NUMBER.

SINCE the architectural lines of every building are somewhat different the spandrel beams must be designed, or rather modified, to meet the special cases, and in order to arrive at the most substantial results the architect and the designer of the structural steel should work in unison. Generally the architectural lines of a building, and its adornment, are designed first, and then the structural steel frame is designed to carry a wall of known shape and weight. This is practical, for before an engineer can design a girder to carry a load he must know its weight and how it is to be applied. But still if this method of procedure is carried too far, and the lines of the building as first laid down, before the structural part has been considered, are strictly adhered to, almost impossible problems may be presented to the designer of the frame, and unnecessary expense incurred. Therefore, the structural engineer, when he finds he is being led into too complicated and expensive construction, should consult the architect, and where possible, without injuring the appearance of the building, the original lines should be changed. This architectural change for the most part would consist of a slight change in design or position of pilasters and cornices and some unimportant angles on the exterior of the building.

As in all masonry, the foundation for the curtain wall is of greatest importance. It seems strange at first sight that no standard construction has been agreed upon for this part of the skeleton construction; but when we consider the short time in which this form of architecture has had to develop, and the fact that most of these frames have been constructed by different engineers, each having his individual ideas in regard to a new form of construction, and the variation in decorated front to be supported, the variety we meet with in this detail is not to be wondered at. A long list of details could be shown of combinations of I beams, channels, Z bars, and angles that are now in use, but since these would be uninteresting to the general reader, and those particularly interested in this form of construction can procure them from books and articles on individual buildings, we will confine ourselves for the present to generalized methods and principles.

Besides carrying the wall, this beam serves as a floor girder to receive the ends of the floor beams, or as a floor beam, and as such receives its part of the floor load, therefore its position must be at a floor level. Its position is also limited between the top of one window and the bottom of the one above. In the horizontal plane its position is very much limited, owing to the fact that its ends are to be connected with the columns.

In regard to the manner of loading this spandrel beam we have first the cornice, or horizontal band of stone ornamentation, which in architectural design is between the windows and on about the same elevation as the spandrel beam, so we can assume that this work will be fastened directly on the outside of the spanbrel beam. From this band to the next band above we have the wall, or rather since the wall is mostly windows, the mullions between the windows. Thus we have two kinds of loading, a uniform loading and a loading at intervals along the beam corresponding to the window spaces. Now neither of these loads are over the center of the web of the beam, but are applied externally by means of supports built to the outside of the beam, and tend to produce a twisting moment in the beam which carried to the columns produce the effect of an eccentric loading there. Where the outside wall is of stone and extends out well from the steel frame this twisting moment is quite an item, and must be balanced by having the floor beams at right angles to the spandrel and attached to it, in this way the structural problem becomes one of the cantilever, the supports for the stone work being a continuation of the floor beams with the spandrel acting as a fulcrum and receiving its load centrally and vertically. For causes of economy, the spandrel beam is generally a deep girder (a plate girder). Now the floor beams instead of ending at this girder can project beyond it, and thus form a shelf on the outside of the structural frame, on which can be built a stone wall of any design. If the spandrel beam can be placed so as to receive the floor beams on its top flange the construction is very simple, otherwise it receives the floor beams somewhere on its web and the continuation of the beams are formed by riveting on the outside of the spandrel. It would give a better form of construction if all supports for walls were built as above, but generally if floor beams are perpendicular to the front wall they are parallel to the side walls, and to have the floor beams making right angle connections with all four walls would cause a little complication in construction at the corners of the building. By so doing, however, we are following correct principles of construction and obviating the undesirable twisting that is produced by loading a detached beam on one side. In all structural steel work, except the skeleton of a steel building, all parts of the construction are in view and the steel can be easily examined to see how it is standing usage, and can be constantly repainted as a protection against rust, and when different members show weakness they can be replaced. But when once the steel of a building is covered with masonry it will never see the light of day again, except in the case of fire or the destruction of the edifice. It is, therefore, very important to be sure that all connections are well made and the steel well coated with paint, and that the stone covering is so constructed as not to allow moisture to attack the steel. It is one of the great faults in this form of construction that the structural material and details cannot be inspected, and considering this fact it is surprising to see with what carelessness these frames are often put together.

After the steel work has been erected and the architect is absolutely certain he has a structure that will stand rigidly

all stains produced by loads and wind, the next work to be taken up is the construction of the outside walls. Before the mason starts his work it is well to see that all spandrel beams are in their correct positions, and that the stone work as designed will fit into its place between beams and columns. When everything fits as designed, the methods of constructing a curtain wall will be the same as those employed in erecting a wall in any other position.

The artistic part of the problem, however, is different from anything ever attempted before, and it is in the design of the front wall that the architect expends his best efforts and brings into play his entire knowledge of architectural adornment.

The architect's first aim seems to be to hide all the structural steel work and give the front of his building the appearance of one solid wall of masonry; then he turns his attention to adornment, and we have presented to our view, in cities where high buildings thrive, all manner of walls, from the rigorously plain to the one on whose face every architectural adornment ever conceived finds a resting place. At first sight some of these fronts may please and awe by their striking appearance, but if we see more of even the finest, we admire it less and look upon it as a most unnatural stone wall, and a feeling that a fraud has been penetrated grows upon us. The use of steel in the structural part of architecture has produced a revolution, but into architecture as an art it has not entered. True, architecture is an adornment of the materials of construction, and since our ideas of architecture are gotten from a time when the use of steel was not know, we associate all architectural effects with the materials used in former times. But now, however, since steel is playing such a part as an architectural material of construction, the time is sure to come when the art will recognize it, and not until that time can we hope for pleasing architectural effects in steel construction.

When the front of a skeleton constructed building can be so designed that each curtain wall of stone will show to the untrained eye that it is merely a covering for an open space between two floor beams and two columns, and the fact that the steel frame is carrying the wall made evident, it will then be that the art of architecture is adapting itself to this form of construction. It is not necessary that the building front should be marred by unsightly beams and columns. They may be entirely covered, but yet have the covering so arranged as to suggest what is behind. And then, again, we may have the beams and columns in full view, ornate, and enframing the individual walls of stone, with the stone and steel blending artistically, presenting to view strength and architectural grandeur. When and how such combinations will be made the future alone can reveal. We can rest assured, however, since stone or other non-metalic materials are non-conductors of heat, that they will always find their place in the curtain walls, and that the structural design of our tall buildings, as they are at present, are too near the ideal to be much improved upon. The architect has shown his ability as a selector of materials and as a constructor. The problem before him now is to adorn his construction, not to hide it.

Subscribe for The California Architect and Building News for the year '98.

HOLLOW TILE FIREPROOFING IN THE PARK ROW SYNDICATE BUILDING.

THE PERSISTENT opposition of the Board of Examiners of New York city to the use of concrete fireproof floor systems in office and mercantile buildings of the best class has been pretty fully discussed in past issues of *Engineering News*. Among the buildings concerning which this contest between the manufacturers of concrete floor systems and the Board of Examiners has been the fiercest is the 30-story Park Row Syndicate Building, now being erected at the corner of Park Row and Ann street, opposite the New York Post-Office, and within a stone's throw of the offices of the *Engineering News*. The history of this dispute has been given from time to time, but a brief review of it will aid in making clear to readers the full significance of the defective work illustrated in the accompanying cuts, which are reproduced from photographs recently taken in the building itself.

The architect's specifications for the Park Row Syndicate Building called for either a concrete floor or a hollow tile floor. The first-named was preferred, owing to its being less costly (we understand the difference in price amounted to $20,000 on this building), and also some 30 per cent lighter than tile, thus reducing the foundation loads about 4500 tons, and considerably lightening the column loads. In designing the steel work the beam spacing was made only 5 ft., and all the suggestions of the Department of Buildings respecting the design of the ironwork to be used with the concrete floor were carried out. Notwithstanding all this, the Board of Examiners successively denied three separate petitions filed for the approval of this construction, and absolutely refused to give any reason for its action. Finally a mandamus was obtained from the courts, compelling the Superintendent of Buildings to pass upon the question whether the concrete floor might be used. This he did in December, 1897, approving the concrete system, but by that time hollow tile had already been placed in about half of the floors, that material being finally adopted to avoid delaying the construction of the building.

The views published herewith show the nature of these hollow tile floors, which the Board of Examiners preferred and which the department of buildings have passed as complying with the building laws. Taking these views up separately, Fig. 1 shows an arch with the key out of center, and in which some of the rings are discontinuous; one key and several blocks are broken; the ring-blocks are not on line with the skewbacks; the steel beam is only partially protected; and various joints are open and uncemented. There are plenty of other arches in the building like this one. Fig. 2 shows on the left side abroken skewbsck and irregular, eccentric key blocks. On the right hand side one skewback is broken and both sets of skewbacks are so much out of line with the rings that the ribs do not stand opposite ribs; some of the blocks are broken and some of the joints are open and uncemented. Fig. 3 shows naked maingirders; broken and discontinuous keystones; unsymmetrical rings, and skewbacks and ribs not opposite each other, while two keystones are not down to their proper level by at least 2 ins. Fig. 4 is especially bad in its defective blocks; use of spalls to fill up gaps, and a skewback set for "side construction."

These defects are chargeable both to the poor workmanship and to the use of imperfect material. Summarized briefly, the characteristic ones are the exposed portions of the steel work, the use of broken tile, eccentricity of keystones and carelessness in opposing rib to rib in the same arch ring, failure to cement joints properly, and generally poor workmanship. In other words, the defects are chargeable to the use of injured material and to the method of handling the material rather than to the nature of the arch material itself; and as many of these faults could be corrected by a more careful supervision of the workmen and a closer inspection and more careful handling of the tiles themselves.

Views Showing Bottoms of Porous Terra Cotta, "End Construction," Fireproof Floors in the Park Row Syndicate Building, New York

the makers of tiles are quite as much interested in better work as the owners of the buildings should be. The question now arises, why is the work of this character not objected to by the Department of Buildings of New York? The law certainly contemplates and demands a different class of workmanship in these hollow-tile arches.

Crude as the applying section of the building law is in the light of present knowledge concerning fireproof floor construction, it does not in any way contemplate or countenance such defective work as is shown by the illustrations. It is perhaps but fair to assume, however, that some of these defects will be remedied in part at least. The exposed beam flanges may yet be covered with the plastering which will of course cover them ultimately, but the structural weaknesses resulting from broken tile, keys out of center, and discontinuous arch rings, cannot be remedied except by reconstruction.

From the views furnished the fact is very clearly brought out, that owing to inefficient inspection tile floor arches of even the best design may be erected in actual construction in a very different manner from that which their design contemplated. *This fact is worth emphasizing here, for the reason that one of the leading arguments made by the advocates of clay tile floor systems against concrete floor arches of all kinds is that inferior material can so easily be used and that the strength of the construction depends so largely upon the manner in which the material is put into place. To the answer that proper engineering supervision and inspection can easily prevent this, the reply of the tile men has been that the nature of their material and the rib construction of the usual flat arch made its perfect installation necessary and ensured sound floor arches even in the absence of inspection. How little basis there is for any such claim, the views which are published here show clearly.—Engineering News.*

CORRESPONDENCE

[The Editor is not responsible for anything which appears in this column.]

NEW YORK, N. Y., May 13, 1898.

Editor California Architect and Building News.

SIR:—In your issue of February and March last, we read with interest a paper of Mr. W. L. B. Jenny, Architect, on "The Best Fireproof Construction for Buildings" and beg to take exception to his sweeping assertion that "the fire-resisting qualities of properly made concrete have been amply proven to be equal if not better than fire-clay tile, as shown by the series of tests carried on by the Building Department of the City of New York."

These OFFICIAL tests of 14 differing systems of fireproof construction were published in "Engineering Record" of New York, September 18th, 25th and October 9th, and we defy any one to form any such conclusion on the results there shown.

Mr. Jenny qotes from the report of Engineer experts to the "Insurance World" of July 1st on the Pittsburgh Fire of May 3, 1897—"There is no probability that any future fire will be fiercer than the one at 'isssue'." That fact not being disputed, we beg to refer him to the report of Mr. S. Albert Reed, manager to the Executive Committee of the Tariff Association of New York, dated June 15, 1897, on the Pittsburg Fire:

Horne Department Store—the one undergoing the severest and crucial test was constructed of hard-burnt terra-cotta: conceded to be inferior in fire-resisting qualities to the porous material—"the steel girders and beams supporting the tile roof are entirely bare and had no protective covering at all. The designers of the building evidently relied for protection upon the suspended ceiling of flat tiles carried by light angle or tee-bars. In this they made their error, *and this error is responsible for nearly all the structural damage to the skeleton and walls.*" Is it fair or just to condem a material because the cheese paring designers of the building failed to avail of its protection, when other parts of the building where it was employed, the results amply demonstrated its efficiency?

"The majority of the floor arches in the path of the falling material were smashed through from roof to ground floor. That the wreck of these floor-arches was caused by this and not by the 'action of fire' is seen from the fact that practically not an arch is broken through anywhere in the building except directly under the section of roof that collapsed." The girders (except those of roof) in this building were admirably protected and not one was injured by the fire—the column protection also did extremely well and was an excellent job."

Horne Office Building—adjacent to above structure was constructed of porous terra-cotta floor-arches and partitions, and the report states: "Of this building little need be said, except that the skeleton, floor arches and walls are apparently intact, structurally, and that the protection was good and did its work effectually."

Such testimony coming from a totally impartial source should carry greater weight than the mere personal opinion of some individual Architect. Mr. Jenny is entitled to his personal opinion but against this we can cite those of a great many other Architects certainly the peers of Mr. Jenny. There are of course various qualities of concrete, but we have only to do with such as is usually found in floor construction, and many will agree with us that a great deal of rubbish at present masquerades as concrete.

As fully 90 per cent of the fire-proof buildings erected in this city and elsewhere are of terra-cotta clay-tile; that the fire proof qualities of such are appreciated by Underwriters is evinced by the fact that they have offered to write the Bank of Commerce and the Clearing House Buildings of New York City, at five cents for five years.

These facts alone, even if they were not reinforced by innumerable others clearly show the trend of opinion among Architects, Owners, Underwriters, etc.

It is also necessary to bear in mind that the limits of efficiency of porous terra-cotta clay tile have never been reached, because the manufacturer simply carries out the designs of the Architect, with results as conclusively shown by the defects in the Horne Department Store.

Truly yours,

HENRY MAURER & SON.

420 E. 23d St., N. Y.

CHICAGO, ILL., April 25, 1898.

To the Editor of the California Architect and Building News.

DEAR SIR:—In reply to your favor of the 16th, would say that the only information which we con give in regard to the condition of the beams and metal lath in the old Chicago Post-Office is, what we saw in them ourselves at the time the builking was torn down. There was at that time, an article written in some paper calling attention to the fact, that iron beams and lath protected by mortar had apparently remained unchanged since the erection of the building, but we do not remember the paper in which the article appeared. This was true so far as we were able to see, but the lath in the building which had been put in when building was erected, was of course, not expanded metal, but sheet metal lath, and that had rusted but very little, and that, on the backside of the lath. All the expanded metal lath that was in the building had been put in in an addition to the building which had been erected only some three years, and was in perfect condition when building was demolished. The iron beams had been painted with red lead, and so far as any of us saw, showed no evidence of rust. As the building had been erected over twenty years, and as the backside of the sheet metal lath would be entirely unprotected, and had not rusted in that time sufficient to weaken or damage it to any appreciable extent, it would seem that open mesh lath like expanded metal or wire cloth embedded in the mortar, would stand for an indefinite length of time without any deterioration. Yours truly,

NORTH WESTERN EXPANDED METAL COMPANY.

WHETHER it is accepted or not, the magnitude of the proposed work makes the proposition to raise the massive capitol of Ohio, and place another story under the structure, of more than passing interest to the building trades and to the architectural and engineering professions. The present building at Columbus being inadequate for the needs of the various state departments, the last legislature provided for the remodeling of the structure. The plans adopted to this end, however, entailed so great an expense that much opposition has been met with, and last week senator Miller introduced a bill to provide funds for the raising of the capitol building as proposed by Mr. Harvey Sheeler of Chicago, who says he will accomplish this feat for $300,000. The Ohio capitol covers more than two acres, and built of native limestone, is one of the most massive buildings in the country. Mr. Sheeler proposes to raise this structure, the weight of which will run high into the thousands of tons, without disturbing the work of a single occupant in the building. He would cut off the building at the base and raise it on jack screws, the entire work of remodeling requiring about three months. The building is to be elevated eighteen feet, which would place three full stories at the disposal of the state authorities. The work of raising this structure will be the largest operation of the kind ever attempted in America.

The proposition of H. Sheeler of Chicago to raise the Ohio capitol, intact, one story, serves to remind us that this trade is keeping pace with the advancement in other lines of building work. This fact is established by the notable operations in this department of building in Chicago. As examples, we may cite the moving of the Immanuel Baptist church, Michigan Avenue and Twenty-third street, the shoring and putting in of new foundations for the Church of the Holy Name, North State and Superior streets. and the recent shoring for the music hall in the Studebaker building, all of which work was accomplished by Mr. Harvey Sheeler, who is the leading exponent of this branch of the work in the west. House moving and shoring has developed into a science, and the operations of to-day involve an accuracy of loads and strength of materials, and an ingenuity and practicality of engineering that frequently equals that required in the more established lines of engineering. The feats accomplished during the past years have in succession astonished even those intimately associated with the building business. It was perhaps one of the more recent of these works that presented a problem so enormous as to be unique in the history of raising, and unparalled in that of the removal of structures, the raising of the Immanuel Baptist church 5 feet 6 inches, and its removal a distance of 51 feet. The building was constructed of limestone and covered a ground area of 93 by 161, with a 225-foot tower resting upon a base 24 feet square. The tower was estimated to weigh 1432 tons, and the entire structure 6652 tons. Besides this enormous tower, the auditorium spanned 63 feet. The successful accomplishment of this feat was an important step in the progress of moving and raising buildings, demonstrating the ability of experienced men to handle a concentrated load and to move large open buildings having virtually no cross walls or heavy partitions binding them together. It was a turning point in the history of the business, since it gave architects and owners thorough confidence in the men who had for twenty years successfully pursued this line in lesser operations, and who are now reaping a reward well merited by their past works.—*The Construction News.*

A SIMPLE METHOD OF MAKING DECORATIVE BRICK.

HERE comes to us from Perth Amboy, from Mr. Antonio A. Mundy, a new method of making decorative brick. He says these ornamental bricks can be made in soft or tempered clay, and the brass plate which contains the negative of the ornament must be placed in the side of the mold. The stiff block of clay is then put in and pressed. The plunger of the press forces both the brass plate and the clay from the box of the press; the plate is then removed from the clay, leaving a perfectly formed brick with the required ornament. This method is applicable to the ordinary hand work which is in general use in many sections, and

AN ORNAMENTAL PANEL OF COMMON BRICK.

which presses the brick on the flat. If a press was so constructed as to press a brick on its edge, then the plate containing the ornament would have to be placed in the bottom of the mold. The picture shows what Mr. Mundy has done. He shows the rare quality of those who take an interest in manufacturing methods, being able to select and adopt a beautiful pattern. Most patterns for decorative brick are so irredeemably ugly that one interested in things artistic says, "If this is machine art, we will have none of it." So it is the machine suffers through no fault of its own and through no fault of the mechanical ingenuity of the designer. In order that the machine which produces artistic form should have success, it should be guided by the hand of an artist. Nearly all mechanical inventors imagine they have the artistic as well as the mechanical touch. This is rarely true; hence the loss to the world of many valuable mechanical ideas.—*The Clay Worker.*

ILLVSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

ACCEPTED plan for Court House, Sonora, Tuolomme County, Wm. Mooser & Son, Architects.

INTERIOR VIEW Church of the Holy Cross, Eddy and Devisadero streets, Shea & Shea, Architects.

COTTAGE in Oakland, A. W. Smith, Architect.

APARTMENT House, corner of Geary and Jones streets, C. A. Meussdorffer, Architect.

THE BEST FIREPROOF CONSTRUCTION FOR BUILDINGS OCCUPIED FOR MERCANTILE PURPOSES.

PAPER READ BY W. L. B. JENNEY BEFORE THE FIRE UNDERWRITERS' ASSOCIATION OF THE NORTHWEST.

CONTINUED FROM LAST ISSUE.

THE RECENT fires have demonstrated that steel is more easily protected than is usually thought. For example, beams in the condition of Fig. 6, that is with the lower flange entirely exposed on the ceiling where it is subjected to the greatest

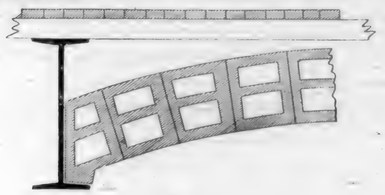

Fig. 7

heat in case of fire. These beams have gone through a severe fire without injury; still, Mr. H. B. Seely in his paper on the art of fireproofing, published in the Engineering News of April 9, 1896, theorizes that a beam in this position is liable, under heat in case of fire, to sag on account of the lower flange of the beam being heated to a considerable degree more than the balance of the beam will necessarily expand, and will cause a deflection of the beam to such an extent that the arches might drop out. Mr. Seely is undoubtedly correct in this theory, still I can find no example of such a serious accident in the reports of any of the fires, which is our only practical test, still as the expense of protecting the lower flange is so small this omission is not to be recommended. The limit by law in height of buildings makes it desirable not to take more than is necessary for the thickness of floors, so that the top flange of girders or beams for convenience is often left uncovered. To this there is less objection. The flange of a beam is such a small part of the whole, and so far removed from the mass of the steel, that no heat that can be produced by the burning of the goods on a floor above will seriously injure the beam. Moreover, the floor is protected by the goods and deluged by the fire department, so that in an ordinary wooden joist building there are records of floors falling from the burning off of the joists and from falling walls, and after the fire was out considerable areas of unburnt floor were found in the basement still covered by partially consumed goods, so that when convenience demands it is not very objectionable to adopt the construction shown in Fig. 7.

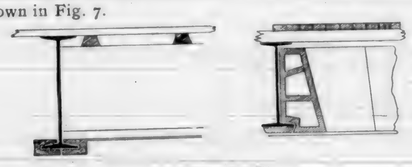

Fig. 8

For partitions the ordinary 3-inch or 4-inch tile the Pittsburg fire shows to be a disappointment. They do not stand any better than wood studding covered on both sides with wire lathing and plastering. Indeed, it is reported that the firemen stated that the hot tile partitions appeared to dissolve and fly into powder as the water struck them. The appraisers noticed that the amount of debris around partitions where considerable portions had been knocked down was very small. From these fire tests it is probable that very satisfactory partitions can be made by steel tees or anchors set vertically, secured top and bottom, covered on both sides by the metal lathing and fireproof plastering (asbestic). Still greater security could be obtained by filling in between lathing with asbestic. The lower six or eight feet of all columns should be protected against damage from shocks by a substantial covering of sheet metal, as boxes of goods are piled up against the columns and they are also subject to be scraped by passing trucks. This outside metal covering will render it impossible for the fireproofing to be stripped off during a fire. There is a still further protection to the columns that I would strongly recommend, which is the filling of the interior of each column with good Portland cement concrete rammed into place. This will protect the interior against rust, and materially strengthen the column as against bending in case of severe fire. This was done in the first nine stories of the Home insurance building in this city.

To be Continued.

VALUABLE INFORMATION CULLED FROM OUR EXCHANGES.

HAVING in mind the destructive warehouse fire of the Chautauqua Lake Ice Co., which had occurred a few days previous, the writer for the *Engineering News*, while in Pittsburg, Pa., took an opportunity to examine the ruins in a superficial manner, and in doing this observed a remarkable case of column distortion. As stated in the description of this fire, published Feb. 17, 1898, the second floor of this building and the columns below were steel, the floor arches being brick, and the column protection of clay tile. These columns were made up of Z-bars and plates and were about 15-in columns. The particular column which attracted attention had assumed the form indicated roughly by the accompanying sketch; that is, it had buckled and shortened up about 1 ft., causing a plainly observable depression or dishing of the floor above. The destortion or bending of the column laterally was very small, the shaft above and below the immediate point of buckling being nearly in its original position. Adjacent columns, though bent, showed no such appearance of buckling, and it is, perhaps, fair to assume that this particular column, heated by the fierce fire, must have sustained a direct blow from falling debris in the collapse of the floors above. This fact, however, the writer was unable to verify, as there was no access to the floor above.

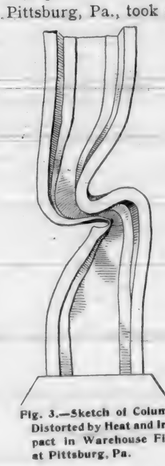

Fig. 3.—Sketch of Column Distorted by Heat and Impact in Warehouse Fire at Pittsburg, Pa.

The incident, however, is most interesting for the manner in which it brings out the reliability of steel as a structural material. Despite its severe distortion, this column still remains in position, and from all appearances was still in condition to carry a pretty heavy load. In the same place a cast-iron column would probably have failed entirely by breaking in two. This fact of toughness was still further evidenced by a close examination of the distorted plates and flanges, which, so far as could be observed, did not show a single crack, though in some places they were bent double. Another noticeable feature was that none of the rivets had been twisted or sheared off by the distortion, though this was sufficient to cause the edges of riveted plates to spread apart between the rivets far enough for the finger to be inserted, while directly at the rivets the two plates were still in contact.

THE statistics of the building department show considerable activity in building operations in St. Louis during the month past, and the prospect for a good building year seems to be as favorable in that city as in any of the larger cities of the middle west. The total number of buildings for which permits were issued during March was 317, and the estimated cost of these structures was $1,096,580, as against 295 buildings, costing $692,007 for the corresponding month in 1897.

This exchange item noting prosperity at the Mound City must be very gratifying to The John Douglas Company, this well-known and popular concern having only recently opened a branch store at that point in order to kept up with the "Course of Empire". Their chain of branch depots now takes in Philadelphia, Chicago, San Francisco, and St. Louis; while their factories at Cincinnati it is currently reported are kept going with full force to supply the demand for their justly popular closets and fittings.

WHAT is known as wire-glass has for some forty years or more been manufactured both in Europe and in the United States. As its name implies it is simply ordinary glass in which wire netting has been introduced while the glass was in the process of being rolled into sheets. Practically the wire insert does not add much to the ductility or strength of the glass sheet, but it has the special quality of keeping the plate together after fracture from impact or heat. In fire-proof qualities it has special value, and is rapidly taking the place of iron fire-proof shutters, as not only resisting fire but admitting light. In a valuable paper on "Recent Developments in the Manufacture and Applications of Wire Glass," by Francis Shuman, read before the Mining and Metallurgical Section of the Franklin Institute, Philadelphia, some forceful illustrations were given of the fire resisting qualities of wire-glass. These practically demonstrated the efficiency of the comparatively new method of resisting fire with a light admitting material. In a series of photographs it was shown that wire glass remained intact after being subjected to a heat, when the walls were cracked, plain glass partly melted, smokestacks had fallen, and fusion had taken place on the face of the brickwork. In other features of utility the authority quoted said:

"In wire-glass the architect and engineer has an article of undoubted value in the light of modern requirements. A medium for enclosing space, fire-proof and water-proof, transmitting light, not liable to disintegration by corrosion or combustion, and difficult of penetration, which still maintains its utility, no matter how much it is sub-divided by cracks, as it will neither leak nor fall apart and injure those below when used in skylights."

It has also been demonstrated that what is known as "rough-ribbed wire glass, such as is used for skylights and windows, adds greatly to the diffusion of light, and the author of the paper further says, "that such rapid strides are being made in perfecting the methods of manufacture, that it will not be long before wire-glass will be generally accepted as an established commercial product, its process of evolution being analogous to that of steel." In resistance to severe storms of snow, hail, etc., the value of wire-glass has been repeatedly demonstrated, and the advantages of its use may be formally summed up in the conclusion reached by experts, that in the near furture, it will be much more extensively used than at present, and in its fire-resisting qualities especially will be found to be of invaluable service. —*The Age of Steel.*

Family Friend—"Does your father suffer much with the rheumatism?" WORRIED DAUGHTER—"No, not half as much as we do."

TRANS-MISSISSIPPI AND INTERNATIONAL EXPOSITION.

JUNE 1 TO NOVEMBER 1, 1898.

JUNE 1, 1898, is the date set for the inauguration of the Trans-Mississippi and International Exposition at Omaha. For five months the gates will open upon a magnificent display of the products, arts, industries and resources of the Greater West.

The Trans-Mississippi Commercial Congress, composed of delegates from every state and territory west of the Mississippi river, by unanimous vote designated Omaha as the Exposition City. The area

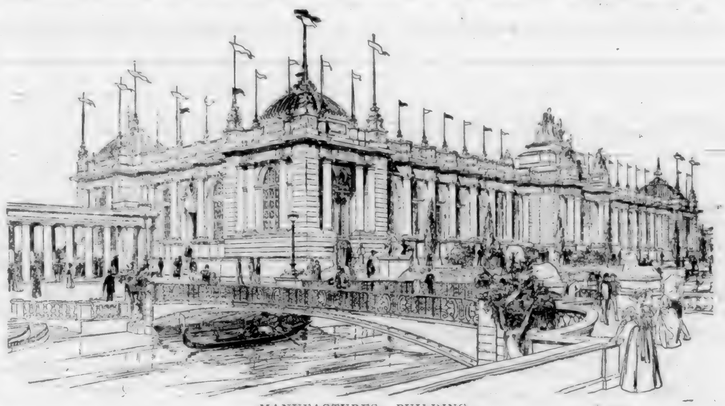
FINE ARTS BUILDING

of the Trans-Mississippi region is more than 2,500,000 square miles, and embraces the great granary of America, vast forests of merchantable timber, and practically all the precious minerals produced in the United States.

A corporation styled the Trans-Mississippi and International Exposition, with a capital of $1,000,000, constituted according to law, is in control of the Exposition. In addition to stock subscriptions and donations, amounting to $500,000, revenues from various sources aggregating not less than $1,000,000 are positively assured. With these resources at command the managers are vigorously pushing the work of preparation of grounds, construction of buildings and of the development of plans to promote the enterprise. The active management of the Exposition is vested in a directory of fifty members, with an executive committee of six department managers. Each department is divided into appropriate bureaus in charge of experts in their respective branches.

The Congress of the United States appropriated $200,000 and made further provision for a government building and exhibits at the Trans-Mississippi and International Exposition. Plans for the Government building have been approved and construction work is in progress. President McKinley has appointed a commission authorized to supervise the collection of exhibits and to have custody of buildings and exhibits during the period of the Exposition.

Facing the Plaza directly inside the main entrance is the Fine Arts Building, in shape a parallelogram 246 feet long and 130 feet wide, the long axis parallel to the Grand Canal. It consists of two separate, symmetrical, domed buildings, connected by a peristylium or open court surrounded by colonnades. The building rests on a ballustraded terrace, and is approached from the Plaza by flights of steps, and also from the avenue bordering the canal, between it and the building. One enters through the portico and vestibule to the dome, central for each building and lighted from the top, forming a suitable place for the effective exhibition of statuary. Surrounding this central feature are the galleries, all lighted by sky-lights, and so arranged as to afford the greatest degree of wall surface for the display of pictures and to allow for the proper circulation of visiting crowds. The two separate buildings offer a better opportunity for the classification of material and at the same time, bring the scale of the architecture to its proper relation with the surroundings and in accord with the general scheme of the Exposition grounds. The colonnade connecting the two parts forms an effective architectural feature, conspicuous from the canal and opposite avenue, and affords a place for the installment of architectural fragments and models, which cannot be so effectively arranged inside the walls. A touch of landscape art lends additional interest to this court. In the exterior design a somewhat free rendering of classic motif has been adopted, the usual severe simplicity of outline being modified sufficiently to bring it in accord with the purpose of the building. The basis of the design is the Corinthian order, which is applied in two dimensions, the larger emphasizing the entrance porticos and repeated on the gables fronting the canal and opposite side; the smaller is adjusted to the height of the flanking walls and connecting peristyle, and serves as a tie to bind the separate elements into one composition. As being quite in accord with the character and purposes of the

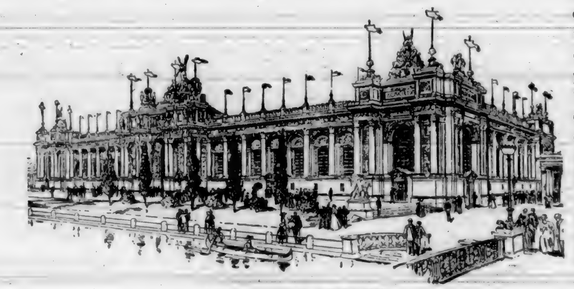


MANUFACTURES BUILDING

building, it was determined to make a liberal use of the sculptors' and painters' art to soften the outline and bring out in greater contrast the severer forms of the architectural

members. To this end the walls behind the columns of the porticos will receive a decorative color treatment, interesting in itself, and forcing into greater prominence their classic outlines. The sculptor is again called upon to crown the pediments and flanking buttresses with groups and figures representing the various arts, and holding out for those who win them, the emblems of success. Eames & Young, Architects, St. Louis.

The Manufactures building designed by John J. Humphreys of Denver, is a handsome structure of the Doric order,



AGRICULTURE BUILDING

modified to comport with nineteenth century requirements. The result is a building of simple dignity, having an air of repose considered requisite in a large building.

The facade presents a frontage of 400 feet, accentuated at center and end with pavilions, sixty-four and forty feet respectively, thereby obtaining sufficient variety of mass. The solidity of these pavilions and their strong perpendicular lines and shadows give a strong contrast of light and shade.

The height of the building to the top of the main cornice is forty feet; the height of order thirty feet, resting on stylobate ten feet high. The height of the center pavilion to the top of the crowning group of statuary is eighty-five feet, while the end pavilion is sixty-five feet to the top of the dome. The large windows, ten feet wide by twenty-four feet high, placed at intervals of sixteen feet, and the roof having a large skylight area, make the interior very bright and cheerful.

The center entrance is twenty-four feet wide by thirty-four feet high, and very rich in decoration, flanked on either side by coupled columns and their accompanying pilasters, standing six feet from the walls. The main cornice breaks around a projection of columns supporting pedestals for groups of statuary. There are also single statues between columns resting on stylobate projected out to receive them. The spandrels above the arch are decorated with bas-reliefs. The end pavilions with their entrances are crowned by shallow domes.

The entire interior elaboration will be confined to classic ornaments. The ceiling, a large barrel vault, with intersecting cross-vault, is richly coffered and elaborately decorated. On the walls it is here proposed to have mural paintings emblematic of manufactures.

The design of the Agriculture building shows a richness of ornament almost to redundancy, which not only gives it the character of an exposition building but suggests the wealth and abundance derived from agriculture. Rich and brilliant color is an important element in the design. This color is applied to the loggias and on the plain wall surfaces, leaving the arches, columns and main architectural parts to stand out in simple, strong masses, having no color themselves but relieved against the colored background. This color treatment produces a beautiful and brilliant effect, whether seen under brilliant sunlight with the strong shadow falling across it, or in half-lights late in the afternoon, reflected in the lagoon or half concealed by the projections of the buildings, as it is seen in the perspective. While the building is of Renaissance or classic type the decorations and ornament will be entirely modeled from agricultural products—festoons of corn and other cereals, and even the common market garden products are given proper place in this decoration. The great semi-circular niche forming the main entrance will be richly decorated in this way in color, and on either side of it there will be figures representing the "Digger" and the "Sower," taken from Millet's famous paintings, supported on either side by lesser figures and the arms of the state and nation. At each side of the great central arch will be recessed niches with rich color decoration, and crowning this central composition will be three sculptured groups, those on either side representing the zodiac and the seasons, while the central figure, crowning the whole composition, will represent "Prosperity," supported by "Labor" and "Integrity." At the corner pavilions there will be figures representing the seasons and the favorable winds, and inscriptions relating to the subject of agriculture. Names of those who have been patrons of agriculture or who have made notable inventions in this field of labor will be inscribed upon the panels in the frieze. The outside dimensions of this building are 148x400. It has a total floor space of 84,260 square feet. The design is the creation of Mr. Cass Gilbert, Architect, St. Paul, Minn.

The design of the Liberal Arts Building is of the French Renaissance school of architecture, harmony and proportion being regulated by the conditions of the other main exhibit buildings in the Grand Court. The Liberal Arts Building is located on the south side of the Grand Canal, near the Arch of the States. The exterior presents the appearance of two stories, the first story or stylobate being low in treatment, with small windows cut into a plain wall surface. The second story is enriched by Corinthian columns, set in pairs with ornamental windows between, and the top of the building is finished with an open balustrade which adds to the general effect.

LIBERAL ARTS BUILDING

At each corner of the building are pavilions with ornamental pediments projecting sufficiently from the main line wall to show a strong corner treatment.

Above the pediments at each corner of the building are

octagonal bases on which will be set groups of statuary. Each group will be composed of four heroic figures, the main one representing the Liberal Arts will be supported by two kneeling figures suggesting industrial art, while in front of all will be a smaller figure supporting a shield on which the attributes of pottery and wrought-iron will be inscribed. An uninterrupted line along the entire front is preserved by the aid of the color-treatment between the pavilions.

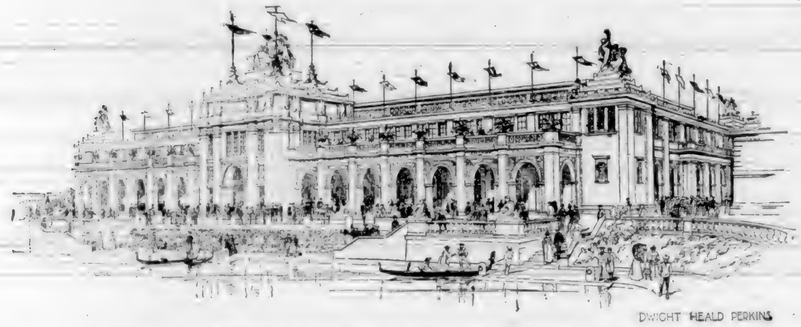
The class of exhibits for which the building is intended will be indicated by the free use of statuary and ornament on the exterior. Color will enter largely into the design and play an important part in the general effect, which will be quiet and dignified, and in strict harmony with the general grouping and masonry of the buildings in the Grand Court, which is buoyant, simple, strong.

The Liberal Arts Building is 246 feet front by 130 feet in depth. The main entrances are on the east, west and north fronts. Fisher & Lawrie, of Omaha, are the architects of the building.

The Machinery and Electricity building is 304 feet front by 144 feet in depth. There are triple entrances on the main floor level in the center of the main front, and similar groups in the centers of the east and west fronts, with four emergency exits in the north wall. In front of the building, flanking both sides of the main entrance, is an open portico sixteen feet wide, running the entire front of the building. The center entrance feature projects beyond the portico, thus forming the grand entrance vestibule. The main floor covers the entire area of the building. Above is a gallery thirty-two feet in width, extending around the four outer walls. The gallery is reached by spacious staircases located in the front corners of the building. This leaves a high central court 248 feet long by 80 feet wide, lighted from the skylights and clere-story windows above the roof.

The character of the exhibits sheltered by this building is shown by the decoration. The ornamental spandrels and panels receive all of their motifs and suggestions from machinery. The cresting at the top is composed of cog-wheels, this principle being carried out in all of the decorations. The underlying principle and function of machinery is symbolized by the groups of statuary on the top of the building. At each of the four corners are groups representing the early supremacy of man over the untamed forces of nature. These forces are represented by wild animals. Men in their youth are seen subduing them for the simple purpose of escaping injury and the preservation of their own lives at the sacrifice of the natural forces. A higher supremacy is shown by the center group, which is the dominating feature of the entire design. In this, man developed beyond the youthful stage, having wisdom, takes these same untamed, unharnessed forces of nature and harnesses them to his chariot, making them do his bidding, symbolizing in a direct way the service which machinery does for man in using the powers of steam, fire, electricity and gravity.

Color enters into the design with maximum importance. The ornaments in the panels under the porticos and over the main entrances will be highly emphasized by small background spaces of strong colors. These are treated in such a way as to give great interest to the spectator near by without detracting from the general quiet and dignity of the view from a distance. The entire building will be a series of yellow and ivory tones, growing more intense as they reach the top, culminating in the dull golden statuary full of primative vigor which surmounts the building and symbolizes its use. The building was designed by Dwight H. Perkins, architect, Chicago.



MACHINERY AND ELECTRICITY BUILDING.

THE COST OF OPERATING ELEVATORS BY STEAM, WATER AND ELECTRICITY.

THE COST of operating elevators by steam, water and electricity has properly become the subject of careful investigation, in view of the extensive and growing use of these appliances. It is stated that in New York, the home of so many sky-scrapers, a larger number of persons are carried vertically in elevators than are transported horizontally by the various forms of traction. Experience with electric elevators in the United States is said to have shown the cost of carrying a useful load 1500 pounds to a height of 100 feet, inclusive of return to starting point, to be one cent. In Berlin and Vienna the cost is reported to be considerably below the figure mentioned. In the former city the cost of lifting by electricity a load of 850 pounds to a height of 80 feet, inclusive of descent, was only one-fifth of a cent.—*The Canadial Architect.*

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

BUILDING NEWS.

SAN DIEGO

Three large art glass window pieces have been placed in the Elks' lodge rooms by W. P. Fuller & Co. The central piece has a magnificent elk's head blasted in the glass while each of the other two companion pieces has worked in the center a large lighted torch.

The foundations are being prepared for General Churchill's new residence, near the Hotel del Coronado.

Ralph Granger has accepted plans for an extension of his music rooms in his house at Paradise Valley. The addition will be 80x30 feet, and the present music room will be used as a reception room for the new apartment.

F. Kreamer was granted a permit to build a two-story and basement house on Fourth street, between A and B, to cost $1600.

F. Heinlein, architect, is seeking to recover $750 for drawing plans for a new stockhouse, warehouse and other buildings for the S. D. Brewing Co.

SAN PEDRO

Plans and specifications for the construction of the new electric railway that is to be built on San Pedro street, with a proposed terminus at San Pedro harbor are now being considered in the office of the en-

MEMBERS OF THE BUILDERS' EXCHANGE.

Plans and Specifications Invited for an Hospital Building.

Public notice is hereby given to architects that competitive plans and specifications for the erection of an hospital building will be received by the Board of Supervisors on MONDAY AFTERNOON, September 12, 1898.

The proposed building to be of modern design and to be constructed of stone or brick, or of both, with all the latest scientific improvements.

The said hospital building to be erected on the lot of land commencing at the most southeasterly corner of a tract of land known as and designated, on the official map of the city and county of San Francisco, as the "Almshouse tract."

The said plans and specifications to be so prepared that the cost of the building shall not exceed in the aggregate the sum of three hundred thousand ($300,000) dollars.

The architect whose plans are adopted will be appointed architect and superintendent of the building, and will be required to give a good and satisfactory bond to insure the completion and construction of the said building for the amount of the cost as made by the said architect. The architects submitting plans determined by the Board to be second, third and fourth in merit will receive premiums of $1000, $750 and $500 respectively, with the understanding that any features of said plans and specifications which may be considered useful or necessary to be embodied in he plans adopted may be used without further cost of charge.

JNO. A. RUSSELL, Clerk.

BEST FOR WARM CLIMATES

Cannot Crack or Peel as Pain Does.

Being *in* the wood, and not wholly on the surface, like paint.

CABOT'S CREOSOTE SHINGLE STAINS

wear better and longer in warm climates than paint, which cracks and peels off under the hot suns. They are he only exterior colorings that do not turn black, and the only treatment that will prevent the blackening of Redwood. No other Stains can contain Creosote, "the best wood preservative known," our patent giving us the sole right to make, sell or advertise Creosote Stains.

The *Siding* of the Kip Mission, above, is Creosote Stained.
Samples and prices on application to

San Francisco, Depot: 421 Market St.

BUILDING NEWS.

gineer, F. W. Wood. It is expected that work will be commenced in a week or so. In the meantime architects are working on the plans for the buildings to be used in connection with the enterprise.

SAN JACINTO

The Riverside county hospital, at South San Jacinto has been destroyed by fire. The building was valued at $20,000, and was covered by $10,000 insurance. Losses on other buildings destroyed at the same time will amount to $5000. Efforts will be made to rebuild at an early date.

BUILDING NEWS.

STOCKTON

Bids were opened on the 16th in the office of Geo. Rushforth, architect, for a cottage for Mrs. Elizabeth Wermuth to be built on Commerce near North, the contract was awarded to Lewis Todd & Co. the lowest bidders, price $1271.

The same architect is preparing plans for a residence for Jerome Haase to be erected on N Stanislaus street the brick foundation is now constructed, the house complete will run to $4000.

Bids were opened in the office of Chas. Beasley & Son May 4th for a two-story lodging house for Mrs. Simon N San Joaquin street, F H Martin was the lowest bidder at $3850

Herbert Baldwin of this city has just broken ground for the erection of a modern cottage which will be built chiefly by day work, Downing & Lemme are the architects

FRESNO

All the bids have been received for W Parker Lyon building at Fresno and the building is well under way and will cost when completed about $9000, George Rushford of Stockton is the architect, and not Beasley & Son as was erroneously stated in our March issue.

LOS ANGELES

The building committee of the city board of education has recommended as a model for the new Pico Heights school, the Union Avenue building, with some modifications, work will commence shortly.

Architects Howard & Train are preparing plans for Alfred Ottaway of two-story eight room residence, to be built at 18th and Bush.

Archt W. S. Gorrett is preparing plans for J. Williams, for cottage on Winfield near Union ave.

Archts. L. B. Valk & Son are preparing plans for Johnson, Keeney & Co, for 3, 7-room 2-story residences Spanish and Italian style; to be built on Lone Star tract and on 36th st near Vermont ave.

J. R. Vogel, 701 South Broadway is taking bids on the erection of a 3-story business block to be built on the northeast corner of Temple street and Broadway.

Competitive plans are being made for the Edison Electric Co., for their proposed new building, East Fourth between Main and Los Angeles.

BUILDING NEWS.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

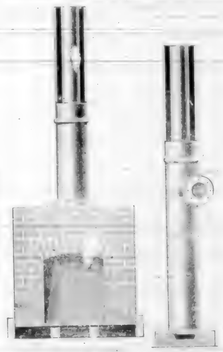
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See **CLAWSON'S LIVE VENTILATOR.** It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

The Yale & Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key, afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," the range of products and grades is such as to meet conditions where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

VOLUME XIX. JUNE 20th, 1898. NUMBER 6.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

PLANS and Specifications for Economical Dwellings, Farm Buildings, Etc.: published by the Continental Fire Ins. Co., New York. A copy will be sent to any property-owner who intends to build, (and will insure his property in the Continental), upon written request to the New York or Chicago office. Also contains proper forms of contracts with builders and architects. Plans are for dwellings costing from $500 to $2500.—Coast Review.

We are sure that architects throughout the country who have read the writings of Mr. F. C. More, President of the Continental Fire Ins. Co., of New York, on Slow Burning Construction, Fire Proofing and kindred subjects, will feel as much in sorrow as in anger, while reading the foregoing announcement. Sorrow, because that is the feeling that comes easily and naturally to all intelligent men when first made aware that one of their number has fallen from his place among men, stricken, as is the case in this instance, by the greed of gain.

As a class, architects are men above the average in intelligence and education, and they will hereafter rate Mr. Moore and his insurance company at their true value.

After the feeling of sorrow has passed, anger, righteous in this case, and deep resentment will have their sway. Then will arise a just demand for retaliation, and the vibration of this demand will be felt wherever architects congregate, as clubs, as unions, in Chapters, or in Institutes.

Mr. Moore is the guiding spirit of the Company but neither will be able to escape the consequences of this act, hich can only be classed with methods that are rated by high class commercial bodies as irregular, being looked upon as the exclusive preserves of venders of corn and bunion plasters, jewelry that is without jewels, dispensary specialities and a thousand other charlatine devices, that are offered every day to a gullable public by a class that are purely fakers.

THE *Examiner via*. Insurance Commissioner Clunie's inside rout, gave to its readers, very recently, some specially constructed information to the effect that, the great fight by the State, for a part of the Foreign Companies revenues had been won after a hard battle, solely by the tactful generalship of the Commissioner. But this item of news from Clunie's seat of war, like some other *Examiner* war dispatches, is pure fiction. The real status of the case appearing the same day, in the columns of the *Evening Bulletin*, which was to the effect, on the authority of the *New York Times*, that "Clunie would keep up the fight" having broken off all negotiations, looking toward a peaceful settlement.

So the Commissioner can be safely *rated* from this on to the end of his term of office, as a "warrior among quakers and a quaker among warriors" and to be feared accordingly.

Our "tumtum," to the doughty warrior would be: Come home and become an Economist—Robin Hoods are out of date.

PRESSURE WANTED FROM THE BOARD OF FIRE UNDERWRITERS OF THE PACIFIC COAST.

TO COMPEL SOME LOCAL ELECTRIC LIGHT AND POWER COMPANIES TO COMPLY WITH "RULES AND REQUIREMENTS" OF THE NATIONAL BOARD.

IN THE April issue of the Architect considerable space was devoted to an *expose* of the underground wiring and service system that had been put in force in this city by The Mutual Electric Light Company *limited*. In that article the attention of readers was particularly drawn to the danger to be apprehended from explosions and fire, from the installation of this company's Red Wood Plank Conduit System, at the underground points of connection with consumers premises, in the down town conjested districts. The incident of the Alma Keith fire in the Phelan Building, was illustrated to prove that the fire was the direct consequence of serving electric current through wooden conduits dumped on the underground shifting sands and having raceways for the lead covered cables that were unsealed at the ends. When damages and accidents arise from such an outfit there should be no trouble in convicting the company establishing it, of criminal negligence. But, bad as the M. E. L. Co.'s methods are they have a rival in their badness in the Central Light and Power Company, "*me too*," *limited*. This company also has a system that is productive of fires in the raceways for electric conductors, which only demonstrates the fact more fully that for underground distribution of electric current there are but two systems which are safe, i. e., Edison tubes or lead covered cables insulated in fireproof ducts.

But to get back to the methods of this Central Company, which was first organized to dispose of the surplus current that the Emporium plant could produce, and finding this part of the business profitable, the Company decided that by enlarging the plant and extending the system they would be in a better position to accomplish the real purpose of their creation. So they enlarged, and since that time have made a practice of installing wires covered with simple cotton braid dipped in a compound known as "Weatherproof" insulation, which in reality is but insulation in name. This kind of wire being made for aerial work only. Such a covering offers no impediment to the passage of current from one conductor to another, or in some cases to the ground. The fire in question was caused by this lack of precaution in not providing proper insulation covering for their conductors, thereby allowing the current to leak from one side of the system to the other setting up an arc which in turn burned away the copper cables, and an entire section of the raceway.

As was stated in the April issue there is always a possibility of these open ducts collecting gasses which might be exploded by a fire of this description causing great damage to adjacent property.

Another source of great danger from fire is a practice by these Companies of installing converters, transformers or pressure reducing devices within or upon walls of buildings or in basement under sidewalks. In the event of the coils burning out within the case a great amount of heat is generated, which soon heats up the boxes to such an extent that in most cases, no matter how it has been installed, the adjacent work will be ignited. The proper, and in fact the only places where transformers should be located are upon poles of companies who distribute by means of overhead conductors or in manholes located in the streets for companies who use the uudergrouud system of distribution.

There should be a municipal law enacted at once prohibiting the installing of transformers within or upon buildings. In the meantime owners and tenants should see to it that no transformers are allowed to be installed either within or upon the buildings they occupy, while insurance Companies should prohibit such criminal practice by restrictions in their policies.

Rule No. 13 a of the Code of the National Board of Fire Underwriters says that *transformers must not* be placed inside of any building unless by special permission of the Inspecting Department having jurisdiction.

Equally as stringent and fully as important is the enforcement of the National Code Rules governing the use of cut out switches and entirely at the discretion of the Board of Fire Underwriters of the Pacific. Yet, notwithstanding this fact, the rules are only partially enforced while some of the Companies are permitted to follow a "go as you please" policy.

Now as the rule is enforced in some instances, the question naturally arises why is it not enforced in all? And as this is one of those "purely a matter of dollars and cents" cases with the Board, it is time that a little home pressure was brought to bear in the right quarter. If the "home pressure" was made out to read something like this: "All Electric Light and Power Companies in this jurisdiction, *shall and must* on and after July 1, 1898, be compelled to place a double pole or triple pole quick break switch at point of entrance of *All* installations, the switches would be so placed."

A word to the wise is generally quite as effective as the proverbial pound of prevention.

HERTZ' EXPERIMENTS ON THE ELECTROMAGNETIC THEORY OF LIGHT.

BY DR. CHAS. A. PERKINS.

PROFESSOR OF PHYSICS AND ELECTRICAL ENGINEERING—UNIVERSITY OF TENNESSEE.

THE Industrial applications of electricity have had an astonishing growth within recent years, but the enlargement of our knowledge of the nature of electricity itself, and its relation with various physical forces, has been no less remarkable.

Faraday was the first to prove the intimate connection between electricity and light, showing that the plane of polarization of light is rotated by an electric current, somewhat as it is rotated when passing through a sugar solution. Faraday further ventured the suggestion that light itself might be an electrical vibration, and that electrical and magnetic forces might be exerted by means of the luminiferous ether, "for it is not at all unlikely that, if there be an ether, it should have other uses than simply the conveyance of radiations." These ideas of Faraday were submitted to mathematical tests by Maxwell, who found them

capable of explaining and accounting for the facts, and upon them he based his well known electromagnetic theory of light.

Everyone who has used a telephone is familiar with the fact that when variable electric currents are passing along a wire, currents are thereby set up in the parallel telephone wire. Maxwell showed that if such a disturbance traveled as a wave from one wire to the other through the air, it should travel with the velocity of light. Maxwell's theory is, in short, that light is itself such a wave of magnetic induction. According to this theory, light is produced by rapidly alternating currents in the luminous body, the direction of the currents being reversed about one thousand million million times per second. Several of the optical properties of bodies can be explained by this theory, especially the extreme opacity of metals; and so strong was the evidence in its favor that the theory was considered by scientists to be highly probable, even in the absence of direct experimental proof. Indeed, currents of such a high rate of alternation are not to be measured by any ordinary electrical apparatus, nor is it easy to experiment upon the velocity of a wave which travels (as does light) with a velocity of 186,000 miles in a second.

LECTURE-ROOM IN THE TECHNICAL COLLEGE AT CARLSRUHE, WHERE HERTZ PERFORMED HIS EXPERIMENTS.

Direct experimental evidence was first obtained eight years ago by Prof. Hertz, in the following way:

Two conductors were placed very near each other and connected, one to each electrode of an induction coil, so that when the coil was in operation sparks should pass from one conductor to the other. Under these circumstances the electricity does not simply jump across the gap and come to rest, but vibrates back and forth in a series of sparks which follow each other at a rate depending upon the shape and size of the conductors used. For those first employed by Hertz they succeed each other at the rate of one hundred million per second. Of course there are not one hundred million sparks—perhaps half a dozen, but these follow each other at this rate. On holding near these sparking conductors a ring or rectangle of wire in which was a break at one point, evidence in its favor that the theory was considered by sparks were seen at this break whenever they occurred between the conductors, showing that the electrical vibration had the same power as an electrical current to induce a current in a neighboring wire. Having calculated the number of vibrations per second in these wires, the next question was whether the induction traveled as a wave, or whether the current was produced by the electrical vibration acting directly and instantly upon the wire.

A large sheet of zinc was hung upon the further wall of the room to reflect the wave of induction, if it were a wave, and as a result it was found that at regular distances from the sparking conductors, the induced spark in the wire could not be obtained, while at intermediate points it was intensified, just as when waves upon the surface of water are reflected back, there are certain points where the surface is at rest, while between these points the water rises and falls in a wave more vigorous than before.

Hertz thus found evidence of the existence of a wave of induction, and succeeded in measuring its length, and from the wave length and the number of vibrations per second, he calculated its velocity. This velocity proved to be, as nearly as his experiments would show, equal to the velocity of light.

To further study the similarity between this electrical wave and light, Hertz made two large parabolic mirrors of sheet zinc. In the focus of one of these he placed the two conductors which were in connection with the induction coil; in the focus of the other he placed two similar conductors, between which a spark would jump when they passed between the first pair.

The mirrors were placed facing each other and acted perfectly as reflectors, concentrating the wave and causing a vigorous sparking in the second pair of conductors. Metallic screens placed between the mirrors showed that the wave traveled in a straight line. By a large prism of pitch the wave was bent out of its course as a beam of light is refracted

so complete was the similarity of the electrical wave to that of light, that not a doubt remains in the mind of any physicist as to the identity, or at least the close connection, of the two.

The extreme interest and importance of these experiments led the writer of this article to desire a picture of the lecture room in the Technical college at Carlsruhe, Germany, where the experiments were carried on. The room has been restored, as far as possible, to its condition at the time of the experiments, and such of Prof. Hertz' apparatus as still remains intact is shown in the cut. The large reflectors are shown in position, with the prism of pitch placed between them, to determine its refractive power. The circles and rectangles of wire, reflecting sheets of metal, a large wooden frame on which are strung wires for experimenting on the "polarization" of the wave, are all shown. The man who is represented holding this large frame in his hand is Mr. Amann, who assisted Prof Hertz in carrying out his measurements. The picture also shows the stoves and iron columns at the sides of the room, which Prof. Hertz afterward believed had introduced certain errors into some of the measurements.—*The University Scientific Magazine.*

CHANGING FORM OF STONE BY PRESSURE.

SOME very remarkable experiments in geology and mineralogy are going on at the present moment in the Workman Engineering building at McGill University, Montreal, Province of Quebec, under the direction of Professor Adams, of the Faculty of Arts and Prof. Nicholson, of the Faculty of Applied Science. These experiments tend to show that a substance so hard and brittle as marble may, under certain conditions be moulded like clay. The experiments in brief consists of placing miniature columns of pure Carrara marble, or stone, in sheaths of iron and submitting them to graduated but long continued pressure, with the result that the marble shortens and bulges so as to swell the iron sheath. The iron being cut away, the marble, no longer cylindrical, but greatly altered in shape, remains as solid and brittle as before. No increase of temperature or other agency than the pressure is applied in producing the above change. The experiments so far conducted have been highly successful, and it has been proved beyond the shadow of a doubt that marble by long continued pressure, may be greatly altered in size, shape and appearance, yet remain in as solid condition as it was before the alteration took place.

These experiments, remarkable in themselves, have implications that make them of peculiar interest to geologists and mineralogists, and incidentally, to sculptors. For the geologist the interest in the proof of the plasticity of marble rests on the light the experiments thrown on certain obscure formations of the earth's crust. They prove that under the conditions of pressure existing deep in the crust, stones may be moulded into new shapes without being melted. In point of fact the moulded marble of these experiments, when examined under the microscope, presents many striking resemblances to certain natural rocks whose peculiar cleavage has heretofore been difficult to explain. The recent discovery at McGill, however, shows that, however brittle a rock may seem to be, it is in reality a plastic substance, capable of flowing into new shapes as surely, if not as readily, as putty or dough is moulded.

In commencing these experiments three years ago, Professors Adams and Nicholson wished to ascertain whether it was possible, by subjecting rocks artifically to pressure under the conditions which obtain in the deeper parts of the earth's crust, to produce in them the deformation and catalastic structures exhibited by the folded rocks of the interior of mountain ranges or of the older formations of the earth. They took into consideration the three factors which combined to bring about the conditions to which rocks are subjected in the deeper parts of the earth's crust: (1) Great pressure from every direction; (2) high temperatures; (3) the action of percolating water.

In the several experiments which have taken place at McGill, the attempt has been made to reproduce only the first of these conditions. In subsequent experiments the endeavor will be made to reproduce all three of them.

The experiments so far conducted have been made chiefly with pure Carrara marble, and the process followed is thus described in detail by Prof. Adams: Columns of marble, two centimeters and two and one half in diameter and about four centimeters in length, are very accurately turned and polished. Heavy wrought iron tubes are then made, imitating the plan adopted in the construction of ordnance, by rolling long strips of Swedish iron and welding the strips to the bar as they are rolled around it. When the welding process is completed, the core of soft iron, around which the Swedish iron has been wound, is drilled out, leaving a tube of welded Swedish iron six millimeters thick, and so constructed that the fibers of the iron run round the tube instead of being parallel to its length. The tube is then very accurately fitted on to a column of marble. This is accomplished by giving a very slight taper to both the column and the interior of the tube, and so arranging it that the marble will pass only half way into the tube when cold.

The tube is then expanded by heating so as to allow the

MARBLE COLUMNS BEFORE AND AFTER PRESSURE

IRON CYLINDER INCLOSING MARBLE READY FOR SQUEEZING

marble to pass completely into it, and at the same time leave about three centimeters of the tube free at either end. On allowing the tube to cool, a perfect contact between the iron and marble is obtained, and it is no longer possible to withdraw the latter. Any very slight failure to fit at any point

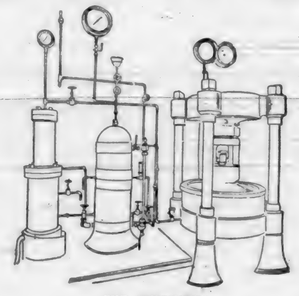
if such a failure exists in any case, is rendered harmless by the fact that under a comparatively low pressure, the limestone is found to be sufficiently elastic not only to fill up any such minute space, but even to stretch the tube, and, on the pressure being relieved, to contract again to its original form, so that it will drop out of the tube which has been thus enlarged.

When the marble has been firmly placed in position in the tube, an accurately fitting sliding steel plug is inserted in either end, and by means of these the marble is submitted to a pressure far above that which would be sufficient to crush it if not so inclosed. The machine employed in obtaining the pressure is so arranged that it (the pressure) might be maintained for weeks, or even months, if required. Under these circumstances the conditions of pressure to which the marble is subjected are those to be found in the "zone of flow" of the earth's crust.

Under the pressure which is applied gradually, and in some cases continued for several weeks, the tube is found to slowly bulge until a very marked enlargement of the portion surrounding the marble takes place. The tube is then cut longitudinally, by means of a milling machine, along two lines opposite to one another.

When thus cut the marble within is found to be firm, so much so in fact that it holds the respective sides of the iron tube, separated as thep are, so tightly together that it is impossible without mechanical aids to tear them apart. By the means of a wedge they can be separated, but the force of

PROF. ADAMS



THE COMPRESSOR

the blow frequently has the effect of splitting the marble through longitudinally.

In one experiment conducted by Professors Adams and Nicholson, the column of marble was reduced from 40 to 21 millimeters in height.

The deformed marble differs somewhat from the original rock in having a dead white color, the glistening cleavage faces of calcite being no longer visible. Although not so hard as the original rock, it is still firm and compact, especially so when its deformation has been carried out very slowly. No accurate measurements as to its strength have yet been made, but it will withstand a very sharp blow, and fragments of it weighing ten grams have been allowed to fall from a height of over eight feet onto a wooden platform from which they have rebounded without breaking. Thin sections of the deformed marble, when examined under the microscope, show that the calcite individuals composing the rock have, in many cases, been twisted and flattened, and, in the majority of cases, a very fine polysynthetic pressure-twinning has been induced in them, with movement along gliding planes, as well as several other structures seen in nature in highly deformed rocks.

To be Continued.

PREVENTION OF CORROSION.

FROM A PAPER READ BEFORE THE WESTERN SOCIETY OF ENGINEERS BY GEN. WILLIAM SOOY SMITH.

THE USE of combustible materials in buildings of all kinds endangers life and property to an extent realized only when we are startled into thinking by some great conflagration or appalling destruction of life by fire. If the great aggregate of destruction of life and property by fire during a single year could be carefully and accurately made up, the world would stand aghast at the horrible revelation. While such wonderful progress has been made during the latter half of the nineteenth century in the development and application of physical science, is it not passing strange that so little has been done to mitigate this stupendous evil? The term "fireproof" is only relative, for there is scarcely anything that will resist the highest known temperatures if applied for a few hours only. And the best and cheapest materials used in buildings do not belong to this class of very refractory substances. The subject of buildings is of vital interest to all mankind. Our convenience, comfort, health and safety depend largely upon the character of our dwellings and of the buildings in which our labor is done and our business transacted. It is especially requisite that the materials employed and the modes of construction of buildings shall be such as to make them strong, durable, safe and economical. They should also be as nearly as possible proof against destruction by fire, or by fire and water combined, as they are generally exposed to the joint action of the two in cases of conflagration.

The "skeleton construction" now so common in large cities for tall buildings is about as faulty and objectionable as it can be when exposed to this combined action. The expansion of the steel the buildings contain is at the rate of a tenth of an inch per foot for a change in temperature of one thousand degrees (red heat). The other materials, stone, brick, terra cotta, etc., each has its own rate of expansion differing from each other and from that of steel. They all differ also in their conductivity of heat. If these materials and steel are raised in temperature equally throughout their whole length, the increase in length will differ in each material, and taking the conditions as they occur in almost all burnings of buildings, the steel will, on this account, be heated much more quickly, and throughout a much greater part of its length, than any of the other materials present. The differences in the total dimensions of the several parts of the building resulting from these causes is so great as to bring about a destructive war between them. This is not mere theory, although it is correct. Close observation of the effects of fire on buildings discloses the same facts.

When a fire is in progress in a building and its parts heated to a high temperature, the fire engines throw powerful streams of cold water on the heated materials, and most of those now commonly employed fly to pieces under this joint action of fire and water. So says chief Swenie, of the Chicago fire department, and all who have become familiar with the effects of fire and water on building material. This is especially true of the light integument of terra cotta built around the steel columns of a skeleton building.

Iron and steel being the strongest materials used in the

construction of buildings, and in proportion to the service to be performed one of the cheapest, have deservedly come to the front rapidly as a building material, particularly in the United States, for the very high buildings that have been erected in the business districts of large cities in which the high prices of lots make it advisable to secure the greatest rentable space practicable on a given area. The experience previously gained in the construction of iron and steel bridges throughout the world prepared the way for the use of these metals in buildings, and to some extent developed correct methods of proportioning and connecting their parts. But it seems remarkable, in view of this experience, that such radical defects still creep into details of iron and steel framing in buildings—such as the flimsy lug and bracket connection of beams and girders with the columns, the eccentricity of loads on the columns, and the want of provision for expansion and contraction of the parts of the skeleton of a building. These defects are easily remedied.

And now supposing that all the metal parts of a building are properly shaped and connected, and all the loads and strains which the skeleton frame is to sustain are amply provided for, two great dangers threatening the safety and durability of the building still remain, viz: the weakening and destruction of the metal members by corrosion or by heat. These dangers are actual and obvious. But the precise rates of weakening by heat, and destruction by corrosion under different circumstances are not as accurately known as they should be. A column of iron or steel, such as those now commonly used in high buildings, would hold little more than its own weight when red hot; and it is well known that there is a dangerous weakening effect of heat at much lower temperatures. The metal while heated loses much of its strength to resist tension and compression, and also loses in greater degree its resistance to lateral fixture, and so the entire skeleton of a building may be deprived of a stiffness necessary to its stability.

It also happens that while the columns, beams and girders are weakened, they are also expanded by heat and unequally, as the degree of heat to which the different members are exposed varies. The unequal expansions of the horizontal beams and girders push the columns out of vertical into buckling positions, rendering almost certain a collapse of the whole structure. This has already occurred in many instances, and is likely to occur whenever fire attacks a skeleton building in which the metal parts are not absolutely protected by proper fireproofing. It also frequently occurs that the horizontal expansions of the beams and girders crack and shove out the walls against which their ends abut.

Many buildings having skeletons of iron and steel imperfectly protected by so-called fire-proofing have failed when heated by fire either in these buildings themselves, or in some instances from the burning of an adjacent building even at a considerable distance away, notably in the case of the Manhattan Savings Bank building, corner of Bleecker street and Broadway, New York, which was ignited by the burning of another building forty feet away and practically destroyed, and the three skeleton (so-called) fireproof buildings ruined by fire in Pittsburg, Pa., on May 3, 1897.

Many other instances may be cited, all teaching the same lesson, viz., that while steel at ordinary atmospheric temperatures is the cheapest, strongest and best building material known, it can only be considered safe and durable when thoroughly protected from high heat and corrosion. The rate of corrosion of iron and steel varies greatly under different circumstances. In pure water, containing no free air, with an airtight covering of paint or imbedded in quicklime, it scarcely corrodes at all, but when in the open air, particularly when alternately wet and dry, it rusts quite rapidly, and when exposed to steam and sulphurous fumes, it is eaten away by corrosion at the rate of one-eighteenth of an inch per annum, as was the case in the floor system of the viaduct in Milwaukee avenue, Chicago, under which locomotives were passing frequently; and corrosion at the same rate occurred in a portion of the western approach of the Eads bridge at St. Louis, where the same circumstances exist.

As the metal in a steel column is usually not more than one-half inch thick, corrosion at the above rate would make a steel building unsafe in less than twenty years. In an iron or steel skeleton building the columns starting at the basement floor, or at the floor at street level, extend to the top of the building. They are hollow and painted only on the outside, and this with paint that is so perishable that it will afford no protection from corrosion after the first five or ten years. The girders are nearly as much exposed as the columns, while the beams are generally bare on the top and bottom surfaces of the flanges, and sometimes over a considerable part of the webs.

Wherever the surfaces inside or outside are left uncovered they are exposed to corrosion that will be more or less rapid according to the temperature and hygrometic conditions of the air surrounding them. And in many instances, particularly in factories, there are destructive elements in the atmosphere, such as sulphur and chlorine, which may cause rapid wasting away of the metal, and which are the more dangerous, as they are apt to escape notice. A steel or iron skeleton building can be made safe and durable only by thorough knowledge of the nature of these metals and careful provision against the dangers that threaten it under all the conditions of their use. Supposing that the structural details are correct, care must next be taken to prevent corrosion. This may be done by covering all metallic surfaces, both inside and outside, with an indestructable coating of a material that will absolutely prevent corrosion. This having been done, all the metal parts must be inclosed in a fireproof and fireproofing material that will not only resist the heat of a conflagration, but so shield the metal from attack by heat as to prevent any considerable charges of its temperature. And this may be best and most certainly accomplished by having an eye to the fireproofing of each individual member.

Slow combustion of buildings can be secured by carefully whitewashing the inside and outside with fireproof material laid on with a brush. And fire departments claim that they can extinguish almost any fire if it is only prevented from spreading too much until they can bring their engines into play. If it of the utmost advantage to protect each building from the danger of ignition in the case of the burning of its neighbors, and this can be at least measurably done by the whitewashing suggested, and by putting fireproof shutters on all windows and openings of every kind. Where there is an open court in a building some sort of fireproof covering should be put upon all parts of such court, and the same protection should be given to stairways and elevator shafts.

The essential characteristics of a fireproofing material for buildings are: First, it must itself be incombustible; second, it must be as nearly as possible a non-conductor of heat; third, it must be strong and durable. While there are very many so-called fireproofing materials in use for which these qualities are claimed, up to a very recent period there

was not one of them that was a good non-conductor of heat, that would stand heating to redness, and being plunged into cold water while red hot, without flying to pieces. Within a few months, after years of careful experimenting, and testing the material, "asbestic" was discovered, which possesses all the requisites above enumerated, as proven by severe tests on a large scale at Montreal, New York, Washington and Chicago.

The requirements of a building are that it shall be strong enough to carry all its loads and resist wind pressure and all other strains to which it may be subjected as a whole or in any of its parts. That it shall be nearly as possible fire and weather proof, and that it shall be durable and not unreasonably costly. Supposing that steel is used for the framework of the structure as being preferable to any other for the frames of large buildings, and that proper shapes and sizes of all parts of such frames have been carefully and correctly determined, and the disposition and connections of these parts have been properly made, it only remains to cover the skeleton of a building inside and outside, roof included, with an integument that shall be fireproof, strong and durable; and, if possible, light, tough and elastic and a good non-conductor of heat and impervious to air or water. Such covering can be made of fireproof plaster of any necessary or desirable thickness, and suitable cornices and mouldings can be worked out of the same material.

As soon as the skeleton is erected every part of it should be covered with a thick coat of the fireproof material laid on with a brush. The metal lathing should then be put on, strengthened where necessary by angle or tie iron covering all parts of the frame and leaving an air space between the lathing and every part of the frame. The great weight of tile, brick and stone now used would thus be dispensed with and the much lighter construction described substituted. A very great saving of weight in the frame itself would be saved and the cost of the necessary foundations of the buildings be greatly reduced. There would be so many other important advantages realized that we need not describe them here. Enough has been said to invite the careful and unprejudiced study and criticism of engineers and architects, and out of this kind of investigation there may come a new system of building that may be the ideal one of the future.—*The Construction News.*

AN OFFICE BUILDING WITH FEATURES OF CONSTRUCTION AND SUB-CONSTRUCTION WORK THAT INVOLVE SPECIAL DESIGN AND ARRANGEMENT.

THE Singer Building, a modern iron and brick office building now approaching completion, is located on the northwest corner of Broadway and Liberty streets, New York city. It is about 60 by 111 feet in size and twelve stories in height. It is designed and will be equipped for office requirements, and although not of unprecedented dimentions nor requiring the elaborate foundations of some of the recent tall office buildings, several features of its construction involve special design and arrangement. Although the columns and floor beams of this building are of iron and steel and the floors, partitions, walls, etc., are of fireproof construction, the steel cage system has not been strictly followed, inasmuch as the ends of floor beams are supported by the brick walls. It was not considered necessary to provide independent steel wall columns, because it was determined to give the walls such dimensions as would insure their thorough stability for the moderate height to which they are carried, and this provision independently developed sufficient strength to make them abundantly adequate to carry the floor loads also.

The position of the columns were, as frequently happens, such as to concentrate heavy loads so near the lots lines as not to be coincident with the geometrical centers of the grillages through which their loads were distributed upon the surface of the sandy soil, at a depth of about 25 feet below the curb. The party walls themselves imposed so heavy a pressure upon their foundation courses that they could not be safely carried by the area of soil directly underneath. Therefore the weights of these walls and some of the adjacent columns were distributed over the grillages by means of an unusual arrangement of cross girders. These enabled the grillages to be set in convenient positions and of suitable dimensions, measurably independent of the center lines of columns and wall, excepting that they were chiefly included between them. The columns were set on short, heavy, multiple-webbed girders that are supported on the converging ends of radial beams, which spread out to support the bottom of the wall overhanging the transverse grillage beam upon which they were laid, and transmitted their loads for distribution upon the soil. In other cases sets of distributing beams were placed diagonally across the corners of the walls to support both sills, and were balanced upon the grillage without receiving any column reactions. In still other places openings in the foundation walls were built over sills composed of steel beams parallel to the axis of the wall, which projected beyond each side of the opening and distributed the weight from these portions of the wall to the grillage across the open space. The distributing beams were heavy sections of the deepest steel girders rolled, while the grillages themselves were composed uniformly of 12-inch steel I-beams, and both grillages and girders were set in solid masses of concrete, which extended 6 inches beyond the metal in every direction and was composed of Portland cement, sand and 2-inch stone in the proportions of 1, 3 and 5. It was well rammed into place, and extended between the grillages to form a continuous floor 6 inches thick over the entire area, with a solid filling of concrete carried down around every column to join the foundation beds.

About the time that work was begun on this building a land slide occurred immediately after a violent rain storm, which carried nearly all of the adjacent surface of Liberty street into the excavation and required a large amount of excavating and back filling. Immediately after the accident the street surface was restored by means of a temporary heavy wooden platform or bridge extending from the front of this building over its vaults, across the street through the front of another large building, which was being simultaneously erected on the opposite corner, thus allowing the foundations, retaining walls, etc., to be built at leisure. The retaining walls of the sidewalk vaults were constructed of special design.

These walls consisted of a core formed by two ring brick arches, with vertical axes built between the flanges of 8-inch vertical steel I-beams, spaced about 5 feet apart and bedded at the bottom in a concrete footing. These tops were joined by 6-inch horizontal I-beams and braced laterally by the sidewalk beams 5 feet apart. The arches themselves were

segmental with a rise of about 6 inches, and were built up solid against an 8-inch straight outside face wall. A 4-inch plain curtain wall was built inside against the flanges of the vertical beams inclosing segmental air spaces behind each arch. This construction was carried around the entire vault perimeter, although obviously the arch principle was not needed on the corner where the curved wall itself formed one long arch, but it was maintained for the sake of uniformity and to continue the sidewalk framework.—*Exchange.*

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

A DESIGN for Church, Reid Bros., Architects.

A STUDY, C. A Meussdorffer, Architect.

RESIDENCE for G. A. Rosenberg, Alameda, M. G. Bugbee, Architect.

FIRST Christian Church, Los Angeles, Austin & Skillings, Architects.

IRON SHUTTERS.

CHIEF Bonner, of the New York fire department, has rudely shaken the faith of those who have hitherto placed their trust in iron doors and shutters as the only proper safeguards against the inroads of fire. He says:

"It is claimed that iron shutters are nearly as good as tin-covered wood shutters, if properly made. This is a mistake. Iron shutters, from my experience, have never withstood fire as the 'Underwriter' shutter has; and they are deceptive in many cases, and have possibly caused more damage by permitting an extension of fire than is generally known. In the case of the Cohnfield fire some years ago, at the corner of Greene and Bleecker streets, iron shutters protected the side of the building on the south side of the Cohnfield building, as well as in the west wall of the Bleecker street building; but, when the flame from the rear of the Cohnfield building took possession of this yard and its surroundings, it opened those iron shutters as if they were unclapped mechanically from the outside; and this is a measure was responsible for the extension of the fire to each of the buildings. I felt confident previous to the opening of those shutters, that the department could hold the fire in check and confine it to the building in which it originated, and I felt some little confidence in the fact that the shutters on both buildings were closed; but I was sadly mistaken, for the first great volume of flame which passed out of the Cohnfield building opened the shutters, as I have already stated, without the slightest trouble, exposing both buildings at the same time to the mercy of the flames. From that time to this I have not taken any stock in iron shutters, and I believe they are deceptive and should not be used where the risk is of any account.—*Fire and Water.*

VALUABLE INFORMATION CULLED FROM OUR EXCHAGES.

A CASE at law in which architects generally are interested is now being tried in New Hampshire. It seems that some two years ago certain trustees invited four architects to prepare competitive sketches for a town hall. Subsequently the plans were received and the trustees reported that the plans came within the required estimate and the competitors were instructed to prepare plans and estimates. These were delivered by the competitors at the time specified. About this time the trustees were induced to admit other competitors and an expert was engaged to adjudicate the competition. The four architects immediately claimed a break in the contract and the trustees were instructed to carry out the original agreement and give the work to one of the four competitors. This they refused to do and awarded the design to another architect. Now one of the original competitors sues for damages.

C. C. Hall, a St. Louis man, brought to Alexandria, Ind., to take charge of the Union Steel Co's chemical laboratory, has made a most remarkable discovery whereby he is enabled to convert limestone into mineral wool; in making experiments lately in hopes of finding a chemical solution needed at the steel mill he found that certain kinds of limestone were converted into a lava when subjected to chemical preparations and heat, instead of becoming brittle. On this he began to work, and has succeeded in making the purest white mineral wool that could be found. In a refined state it can be used in the finer textures, and in the rough state it partakes of the nature of asbestos.

UNDER a new city ordinance, Chicago contractors will hereafter have to pay the city a small anual fee, and file a bond of $10,000 every year to indemnify the city for damages to sidewalks in the laying of foundations. Standpipes and metallic fire escapes must be places on all buildings, old and new, four stories or more in height. When a staircase surrounds an elevator shaft there must be a fireproof wall between the shaft and the stairs, and electro-glazed prisms are favored for shutters for windows in alleys, as they withstand heat, and at the same time are broken more easily than iron or wire, if the firemen wish to enter the building.

A REPORT of the assistant secretary of the United States Navy on fireproof material makes the recommendation that no wood at all be used on torpedo boats. The fire proofed wood which has been tried on some ships has, he states, a tendency to corrode steel with which it may be in contact. Further, the treatment weakens the wood and renders it hard to tool. Laid on decks it wears badly, and if subjected to constant wetting appears to lose its fireproof properties. From these considerations the secretary recommends that the material shall not be used for decking, but thinks it has advantages for interior joiner work, which is less exposed to the action of water.

THE responsibility of the architect for faulty construction has been greatly increased during the past few years. This is especially true of architects in Illinois. The passage of the state law licensing architects and regulating the practice of architecture as a profession increased the moral burden of responsibility for faulty construction with the legal rider of a revocation of the architect's license if he shall endanger life and property by criminal carelessness or malpractice. The recently revised building ordinances of Chicago have drawn the bonds of responsibility of the architect closer than heretofore, and the recent fires in this city, coupled with the loss of life, will result in a closer and more literal enforcement of the provisions of the new laws. Not only do the Chicago ordinances state that any person or persons violating the provisions of the building ordinances shall be each fined in a sum of not less than one hundred dollars, but it specifies that "any architect, having charge of such building, who shall permit it to be constructed in violation of this ordinance, shall be liable to the penalties herein provided and imposed." The stopping of the work of the reconstruction of the Holbrook building at 312 Wabash avenue may be taken as evidence of increased vigilance upon the part of the city building department, and a careful perusal of the new ordinances may save the architect future unpleasant complications.

FIREPROOFING.

READ BEFORE THE WESTERN SOCIETY OF ENGINEERS BY FRANK B. ABBOTT.

OUR MODERN steel skeleton building marks an era in the history of architecture. In times prehistoric, in the Drudical epoch, if I may be permitted the term, the architect practicing without a license but still building wisely and well according to his light and with the primitive materials then available, set up on end, at regular intervals, rough hewn or nature shaped posts of stone. Upon these posts and spanning the intervening spaces he laid other pieces of stone, upon these horizontal pieces he laid wooden poles covering the whole with leaves and grass, and right here the simple principles underlying all architectural form was born, the column and the lintel. Through all the ages that have intervened we have not improved much upon these principles. We have varied them it is true, we have used various materials from which to construct these two primary members, we have embellished them, we have placed a basket with same acanthus leaves growing around it on top of the column, we have inscribed the names of dead heroes on the lintels, but the column is a column still and the lintel is still a lintel, and while some of our profession seem never to have heard the old adage, "Ornament construction but do not construct ornament," and in this violation of the adage have at times almost concealed the true functions of column and lintel, still the two supporting members remain and will remain until the end of time or until nature rearranges its laws. These two members are about all there is in a building aside from the finish and embellishment, for the beams and girders are only ramifications of the lintel, and struts and pilasters only undeveloped columns.

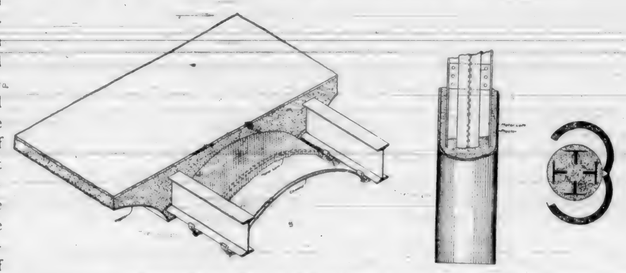
It is only a question of time when all buildings will be of steel construction, residences, churches, warehouses. Our navy to-day is all steel from keel to turret, and our residences and business buildings will be all steel in the near future and not fire traps for the destruction of life and property. The word "fire" reminds me that I was not expected to talk about architecture, or about steel construction of buildings, but about fireproofing, but as you have undoubtedly perceived, the preceeding remarks are intended as a preface to the subject matter, and, it is needless to say, that fireproofing wooden construction is a paradox and a delusion, and fireproofing stone absurd, therefore it is assumed that when we speak of fireproofing, we mean protecting steel and iron from the attacks of fire, for while steel is the best building material, it has an enemy, yes, it has two enemies, and in the light of recent investigations it is difficult to say which is the greater.

Investigations recently made by the American Society of Mechanical Engineers as to the condition of the steel in the frames of modern office buildings, reports of which investigations were published in volume 15 and 16 of their transactions, show that in many instances the metal had been seriously attacked by corrosion, and there is small room for doubt that were the tile and terra cotta coverings removed from the steel skeleton of our great modern buildings, we should find that rust has set up its dangerous work in many places. Putting a covering over the metal and calling this covering fireproofing does not insure the metal against corrosion, and sometimes unfortunately not against fire. Fire and corrosion then, are the enemies of steel, the one bold, flagrant, irresistible, the other unseen, silent, insidious. Now if we can keep these two enemies at bay we have a perfect and enduring building.

To prevent the corrosion of the metal is not, however, a difficult matter, as it is only necessary to keep out oxygen or moisture, but I wish to remarke in passing that painting the metal is but a short-lived protection, as wherever air currents occur along the steel members, as is frequently the case where hollow air spaces are left between the fireproof covering and the steel, particularly where these air currents

originate in basements or areas where there is moisture and warmth combined, the painting will protect the metal at best but a few months.

Now a fireproofing material of whatever kind it may be to properly perform its work must entirely cover the metal on every side, wholly envelope it, and be of such nature and thickness as will prevent the transmission of heat. This being so, it follows as a natural sequence that if this fireproofing material has the further quality of being impervious to air or moisture, we then can successfully resist the two enemies of steel, in buildings, with one material. So far as history is concerned, it shows that iron embedded in cement and concrete is preserved from rust, as, for example, iron cramps lain in cement joints and used to hold together the lintels of the Parthenon have been found intact, and anchors embedded in the concrete of the walls of the Coliseum of Rome when brought to light are as bright and untarnished as when new, and coming down to our own times, we bury the steel beams of foundations in concrete to prevent the action of rust and the inside of the bottoms of the steel ships of our navy are protected from rust by a covering of Portland cement.



SECTIONS SHOWING APPLICATION OF CONCRETE.

Therefore, if our fireproof material is concrete and wholly protects the metal from fire, it will preserve it from rust. The proposition advanced herein then is to surround every column, beam, strut, or other structural member with concrete, and not only surround the metal but envelope it on every side, leaving no air spaces externally or internally. What kind of concrete is best for the purpose? My experience shows that the best concrete is: First, one that is a fire resistant; second, one that will not expand under the action of heat; third, one that is light; fourth, one that is sufficiently strong for the purpose; fifth, one that is high in lime. There is a number of substances which mixed with mortar or cement, will make concrete which will conform in the main requirements to that above described, but they are more or less dense and therefore heavy. In the 10-story manufacturing building, 171-173 Canal street, Chicago, the concrete fire and rust proofing is made of four of cinders to one of cement. These floors weigh about 25 pounds per square foot.

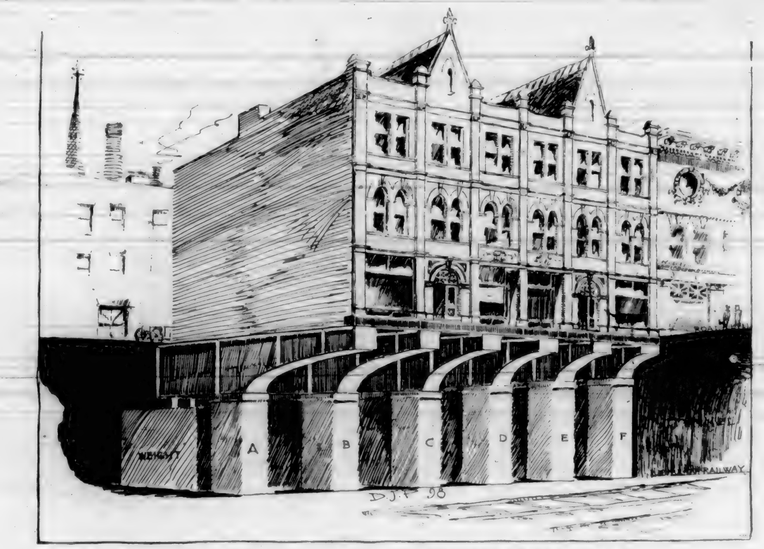
The lime of commerce is one of the best fire resistants known and concrete for fireproofing purposes is best that contains the greatest proportion of this ingredient, consistent with strength. In the Druecker warehouse now being built, the columns will be protected by concrete made of one part natural rock cement, one part lime putty and four parts cinders. This concrete material will be rammed into the internal cavaties as well as entirely surrounding the columns, the nearest approach of the metal to the air being 4 inches when the column is finished. After the concrete is set it will be covered with a metal lath, on which will be spread a thick coat of dense, hard mortar. Wooden cylinders 4 inches long and made of 2-inch staves hinged so as to open in the direction of their length will be set around the columns and the concrete rammed into place from the top. As soon as one 4-foot section is constructed on top of the first, and this process continued to the top of the column before floors are put in, thus securing a continuous envelope to the column, without joins from basement to roof. The metal lath is used to provide a better key for the mortar finish and to protect the concrete from possible injury under high temperatures.

The steel will have no painting whatever, but will be cleaned of mill scale and other foreign substances at the building, before concreting, since nothing should be put upon the steel to prevent the perfect adhesion of the cement to the metal, as the cement in the concrete settles about the metal and deposits upon its surface a coating while the concrete is being rammed into place. The external columns will be covered with hollow bricks and the spaces inside this outside covering filled with concrete material, the same as other columns. In any building during a fire the point most fiercely assailed by the heat and flames is the floor construction directly above the fire, and there has been plenty of evidence to support the statement that if the floor construction of any building is impregnable to fire, which may occur or originate in any story, then the damage from fire in such a building will be slight so far as the building itself is concerned. The fierce heat generated in burning buildings is caused by the floors burning away and thereby creating a draught through several stories.

In a private test made on several pieces of cinder concrete in a furnace under a boiler, the test lasting about forty minutes, the temperature was raised to the fusing point of wrought-iron without showing any serious injury to the concrete blocks These concrete blocks were 5x8x10 inches and various grades of concrete were used. The concrete being made of one part cement, one part lime, 4 parts cinders.

W. H Birkmire, in his recent work, "The Planning and Construction of High Office Buildings," says on page 129: "Of the use of concrete in construction little need be said. It is a conceded fact by those authorities who have given the subject the most thorough and careful study that concrete as a fire-resisting material is unequaled. After the great conflagration in Chicago the committee who examined the effects of this fire reported that concrete was the most thoroughly fire-resisting material that had passed through the ordeal. Iron and steel when completely embedded in and protected by the concrete which forms around it in a homogeneous cast, is undoubtedly better protected from the effects of heat and corrosion than would be possible by any other method. In Europe where concrete has been used in building construction for centuries past, its efficiency is better understood than in this country. More buildings are standing in Europe to-day which were constructed of concrete more than 500 years ago, and which have withstood the attacks of cold and heat for all these centuries and are yet in a good state of preservation."

The relation that fireproofing bears to insurance is an intimate one, and the insurance companies are close observers of condition during fires, and their discernment of the value of fireproof material is constantly being sharpened by destructive fires. Comparisons are odious but facts are stubborn things. In the Felix & Marston warehouse, built about four years ago, which building was fireproofed with cinder concrete in general manner, as shown by details of construction exhibited here, the rate of insurance made by the insurance companies on the building was 45 cents, and that, too, on a building filled from cellar to roof with a very inflammable material, namely, wooden and woolen ware. This is the lowest rate in Chicago on a warehouse stored with this nature of stocks. Mill construction has proven a great disappointment to the architect, the owner and the insurance companies, and while Mr. Atkinson may have been able to produce first-class revenue for the New England mutuals, he has not told us how to arrest the progress of a fire that has once gotton under headway in a mill constructed building. This type of construction in large cities will undoubtedly soon become obsolete.—*The Construction News.*



A BUILDING CURIOSITY IN CARR'S LANE, BIRMINGHAM.

BIRMINGHAM'S BUILDING CURIOSITY.

THE INTEREST of the general public in matters of engineering difficulty is not usually marked, but we give from the *Birmingham Post* a sketch that will help to make clear the nature of an undertaking at present in its early stages in Carr's-lane which may arose considerable interest.

This novelty has been described as "suspending a building"; but the term is hardly correct, and disappointment has been expressed by those who have visited the spot under the impression that they would find a building hanging in the air, "suspended" by goodness knows what! The drawing mentioned will assist in making clear our description. The problem was to deal with a valuable site, with an equally valuable frontage, rendered almost valueless because the tunnel of the Great Western Railway passed under the whole of the frontage, and that so near the surface as to preclude the use of cross-girders. Various architects and engineers had attempted to solve the knotty question of the utilization of the land, but none of the many plans submitted would the engineers of the railway company accept, Mr. Ingles, the engineer of the company, laying it down as a sine qua non that not the slightest weight should rest upon the tunnel. To meet this difficulty, Mr. Ralph Heaton, the architect engaged, has devised a system of cantilevers, as illustrated, to support the three story erection of warehouses and offices designed to cover the space. The building from front to back is 44ft. deep. At the A cantilever the building overhangs the tunnel 25 feet, which leaves only nineteen feet, resting upon a solid foundation. This cantilever supports 270 tons of the building, and as the front or over-hanging part is so much longer than the other, a gigantic weight in the form of a concrete block some 16ft. by 15ft., and weighing 160 tons, is suspended from the short end of the cantilever by steel rods 22 ft. long. The cantilever, B, supports the greatest load, 375 tons, and overhangs 21ft. C supports 360 tons and overhangs 14 ft, the overhang gradually diminishing to 4th at F.

The drawing will convey an idea of the entire arrangement and the substantial nature of the building to be erected, although it is not entirely accurate with regard to the contilever A, which for clearness is shown below the roadway, while, as a matter of fact, it will be some 2ft. above the footpath; and from it will really be "suspended" the paved carriage way that leads to the rear of the building. By this ingenious device will at last be utilized a site which has long been a puzzle to many. The larger cantilevers are at present being placed in position, and when once the ground line is reached and the mystery of the foundations covered in the curious features of the building will be entirely lost to sight.—*Copy of drawing from the Illustrated Carpenter and Builder, London, England.*

THE KEELY MOTOR UP TO DATE.

PROCEEDINGS OF ENGINEERS' CLUB OF PHILADELPHIA.

BY E. J. SCOTT, ACTIVE MEMBER.

THE Keely motor has been a matter of greater or less public interest for twenty-five years, and yet there is now as little general knowledge of what it is as when it was first announced. Probably no other enterprise making as little actual progress was ever kept alive so long. Certainly no other enterprise ever enlisted so much capital without showing more substantial reasons for investing it.

Keely has carefully guarded his secret; even the courts could not extract it from him. In fact the secret constituted the entire property of which Keely was the treasurer, and even the company formed to exploit his supposed invention, has never been able to wrest it from him. Any effort on the part of the stockholders to do so has been met with the objection that Keely controlled the situation and the value of their property depended upon keeping on good terms with him.

Many investigators, scientific and otherwise, have seen his experiments; United States Government officials and experts have witnessed them; capitalists, with millions at their disposal, have sought to control his inventions, yet there has always been an unreadiness on the part of the inventor to do anything practical; he was always just within reach of the goal, but never got there. He is now over seventy years of age, and the possibilities of his secret dying with him have aroused those who have supplied him with funds to the desirability of having him communicate his knowledge to someone who could continue his work.

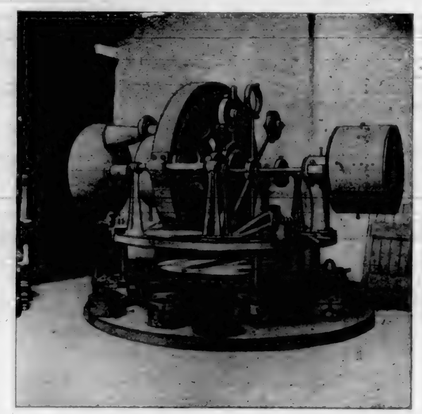
With this idea, Mrs. Bloomfield H. Moore, who has for many years been his staunch supporter through evil and good report, and who, with Keely, controls the enterprise, made an effort to find a suitable person to fill that role. Well-known scientists who were invited to investigate the subject, courteously declined. This was not surprising, for no person had even been given a fair opportunity to observe the operation of Keely's apparatus, and it was a mere waste of time to visit his workshop.

In the fall of 1895, Mrs. Moore, who had but a few weeks before returned from Europe, where she had resided for many years, asked Mr. E. A. Scott to make a visit with her to Mr. Keely's laboratory. She was desirous that someone qualified to speak should see enough of what Keely had done to be able to say that he had discovered a force hitherto unknown, and that he had, to some extent at least, succeeded in harnessing it. Mr. Scott had interviewed Keely on the subject in 1894, and was familiar with the results of former attempts to discover the secrets of Keely's laboratory, which had all been negative because of lack of suitable facilities for observation. He was also familiar with the views of the Government experts who witnessed some experiments made by Keely at Fort Lafayette in 1886.

The visit was made November 9, 1897, and the afternoon of that day was pleasantly spent with Keely at his workshop. The impression which the inventor made upon his visitor, which the latter published at the time in a semi-serious article, is given here in a brief extract from that article:

"John W. Keely is sixty-eight years old, although he looks much younger. He is a large, powerfully built man, with a large head, square shaven jaws, with heavy, dark side-whiskers, tinged with gray, and dark eyes which move rapidly. His movements are nervously quick and his speech is extremely rapid, as though it could not catch up with his thought. He impresses one with the belief that he is absorbed in what he calls his life study, that time is short, and that every nerve must be strained to accomplish practical results while life remains."

A very little conversation satisfied the visitor that he must abandon all preconceived notions of natural philosophy if he thought to make any progress in the study of the new power. The laws of gravity, as laid down by Newton; magnetism, as formulated by Faraday, Henry and others; light and heat, as outlined by Lord Kelvin, and the correlation of forces had to give way to this mysterous force, which practically creates something out of nothing, if we may unquestionably adopt the discoverer's theories.



AERIAL PROPELLER.

At this first interview enough was seen to satisfy the visitor that some, at least, of the experiments witnessed did not depend for their explanation upon any hitherto unknown force. He did not then, nor at any other time, give Keely any reason to think that he did not implicitly believe that the moving force was "Apergy," the name given to this as yet undemonstrated force. Among the experiments witnessed on that first afternoon were (1) The continuing vibration of a short bar of steel which had been "vitalized." (2) The suspension of a heavy weight by simple contact with two small strips of steel, and dropping it by striking a tuning-fork. (3) The levitation experiment, by which heavy weights rise and fall in water in response to notes produced on certain pitches. (4) The constant revolution of a small brass wheel after having been put in step with the vibratory force called "Apergy."

To be continued.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL—and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

☞ *See a full size working model at our store.*

Architects Krause and Jenkins are preparing plans for Mrs. Mary R. Conway, for extensive alterations and additions on the corner of Second and Los Angeles streets.

Architect Brinkoff has prepared plans for residence for G. W. Cox to be built on Orange steert.

Plans and Specifications Invited for an Hospital Building.

Public notice is hereby given to architects that competitive plans and specifications for the erection of an hospital building will be received by the Board of Supervisors on MONDAY AFTERNOON, September 12, 1898.

The proposed building to be of modern design and to be constructed of stone or brick, or of both, with all the latest scientific improvements.

The said hospital building to be erected on the lot of land commencing at the most southeasterly corner of a tract of land known as and designated, on the official map of the city and county of San Francisco, as the "Almshouse tract."

The said plans and specifications to be so prepared that the cost of the building shall not exceed in the aggregate the sum of three hundred thousand ($300,000) dollars.

The architect whose plans are adopted will be appointed architect and superintendent of the building, and will be required to give a good and satisfactory bond to insure the completion and construction of the said building for the amount of the cost as made by the said architect. The architects submitting plans determined by the Board to be second, third and fourth in merit will receive premiums of $1000, $750 and $500 respectively, with the understanding that any features of said plans and specifications which may be considered useful or necessary to be embodied in he plans adopted may be used without urther cost of charge.

JNO. A. RUSSELL, Clerk.

THE

Rapid Safety Filter

411 MISSION ST., Bet. 1st and Fremont. SAN FRANCISCO, CAL.

BEST FOR WARM CLIMATES

Cannot Crack or Peel as Paint Does.

Being *in* the wood, and not wholly on the surface, like paint.

CABOT'S CREOSOTE SHINGLE STAINS

wear better and longer in warm climates than paint, which cracks and peels off under the hot sun. They are the only exterior colorings that do not turn black, and the only treatment that will prevent the blackening of Redwood. No other Stains can contain Creosote, "the best wood preservative known," our patent giving us the sole right to make, sell or advertise Creosote Stains.

The *Siding* of the Kip Mission, above, is Creosote Stained.
Samples and prices on application to

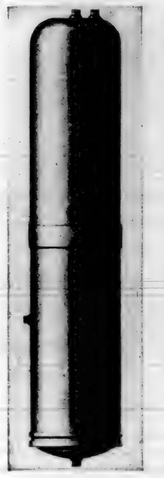
CHARLES J. WATERHOUSE, Agent.

SAMUEL CABOT, Sole Manufacturer, Boston, Mass.

Also: Cabot's Sheathing and Deafening Quilt, Cabot's Mortar Colors, Cabot's Brick Preservative, Cabot's Anti-Pyre.



For Sanitary Reasons

You Should Specify the

Brown Brothers' Cold Drawn Seamless Copper House Range Boiler.

The smooth copper surface is heavily tinned inside. This absolutely insures against corrosion or rusting of any kind and affords no rusting place for sediment. You alway get

Clean Hot Water

rown Boilers are made of two pieces of cold drawn copper, united under great hydraulic pressure, so that they are practically one piece. No seams nor rivets, means freedom from leaks. The inside spiral rib guarantees against collapse. Ordinary weight boilers stand a pressure of 150 lbs. to the square inch; extra heavy, 200 lbs.

Boiler Booklets sent on request.

PHŒNIX

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

PURE

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

PAINT

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

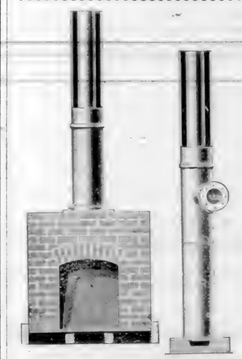
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET, SAN FRANCISCO.

TELEPHONE SOUTH 257.

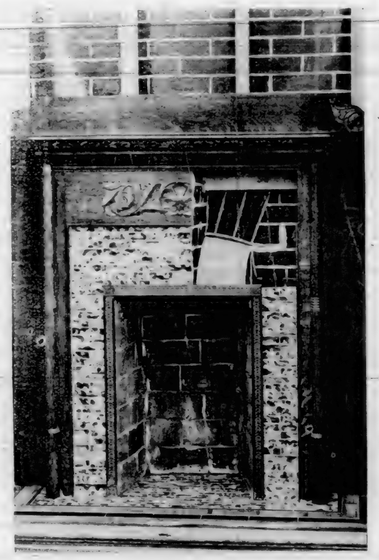
CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.



See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

The Yale & Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key, afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," the range of products and grades is such as to meet conditions where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

VOLUME XIX. JULY 20th, 1898. NUMBER 7.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

HON. U. S. Grant in the capacity of an aspirant for the Senatorship from California in presenting his views on public questions to the people of this State comes out boldly as an advocate of "Expansion" as the true future course of the nation.

Of local benefits to be derived by such a national policy Mr. Grant expresses himself as follows:

"It is my belief that California, and indeed the nation, stands at the threshold of a new and most promising era. The national tendency toward expansion must benefit the West to an extent beyond all our calculations. We have before us a struggle and a hard struggle. This State must control and must be supreme on this Western coast, and to California must come the vast trade that will properly belong to it, with the new doctrine of expansion. The Northwest will enter the contest for the trade which is to come from the Orient and the isles of the sea. The importance of close and intelligent attention to this subject seems to me to be of the highest importance. Our share of this trade, the definition of our status with respect to it, must be settled early after the present war ceases."

Here at least there will be common ground where the unity of interests will have so much in common and, so much in unity, that the combined forces shall be practically irresistible, and we of the far West should see to it that this policy of "expansion" become irrepressible.

WE HAVE published the following communication from Mr. B. J. S. Cahill relative to a notice appearing in the *Architectural Review*, Vol. IV. No. VII. The *critique* is undoubtedly an unjust one and well merits a reply. The architect explains that stress of work did not permit his giving the subject his attention earlier.—EDITOR.

In discussing the above alternate designs for a church appearing in outline transcript form in the CALIFORNIA ARCHITECT the critic of the *Architectural Review* solemnly delivers himself of the following announcement—"A church first and foremost should have a certain dignified, religious air, which" he goes on to say with more conviction and less truth "unfortunately this design" (No. 1) "does not possess."

Permit me to parody this profound statement. Any criticism first and foremost should have a certain air of justness and intelligence about it which quite fortunately for me, this criticism does not possess.

For instance, Mr. Critic says, with the only flash of discernment anywhere enlightening his review, "The general style is somewhat Mexican in its treatment," but then instead of logically following up the clue and seeing the architect's development of his theme in this light, he goes on to make the extraordinary assertion that "whatever ornament the edifice has, seems to recall rather the Masonic emblem than the motives usually observed in church architecture." The ornamental motives are Mexican truly enough, but I challenge anyone to show a single feature that has a Masonic rather than an ecclesiastical character.

The next statement of the critic is equally unfortunate. He says "the window openings are unstudied." As a matter of fact the window openings are very carefully studied throughout with reference equally to their size, portion, detail and diversity.

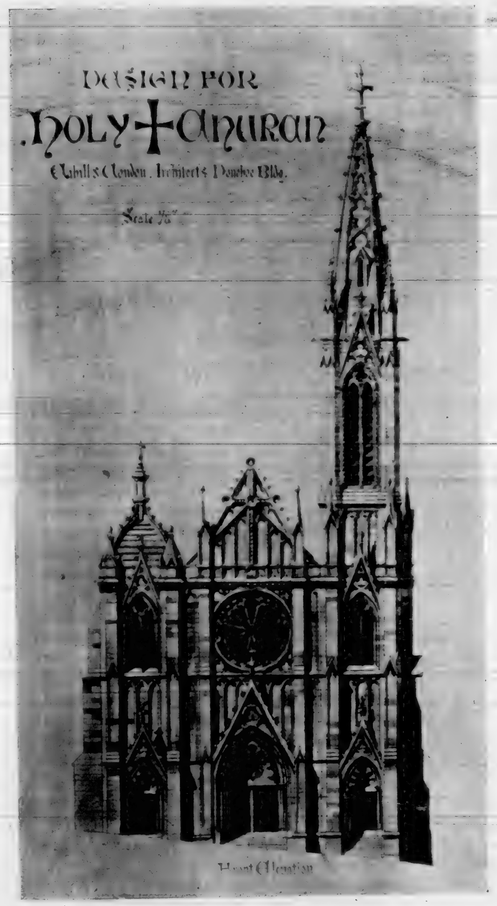
In the upper stories of the towers they are studiedly ornate, those in the Bell tower being studiedly different from those in the Baptistry tower. The large central window opening is studiedly odd in its Mexican contour and is large because it faces south and illumines the entire church, while the windows in the towers at each side are small and quite studied in their position proclaiming as they frankly do that they light a stairway and not an aisle. That the low position of these front tower windows necessitates a large space of plain wall surface above is a matter that needs neither correction nor apology. Finally the square shaped window openings in the basement story of the towers, are studied in the massive simplicity peculiar to the Spanish American style. They are small, since, where little light is needed little light is shown.

The critic could not of course be supposed to know it, but the problem the architect had to solve was this. A Roman Catholic Church had to be planned to seat 800 people on a restricted lot. The building was to be so designed that it could be roofed in and ready for use at the *least possible* outlay. At the same time when the towers were added it should not be lacking in appropriate beauty and impressiveness.

This problem of combining Finance with Fine Arts seemed to the architect to be happily solved by adopting a Mexican or Spanish American style. This style permitted a solid simplicity of treatment up to the main roof line. It justified the candid use of stucco where plain wall surfaces occurred in the front as well as on the side. It dispensed with the costly exactions of ordinary classic and easily allowed a logical harmony of treatment to clothe the entire body of the building and so redeem it of the vulgar error of being a mere show facade of stone architecture with the balance of the walls in bare brick. With these advantages in the way of inexpensive simplicity in the first portion built the style demanded that the towers to be built afterwards should exhibit and express the full value and efflorescence of the architectural motives so sternly repressed in the lower parts. To further compensate for the severity of superficies throughout it was thought that the introduction of a red tile roof over aisles and porches would supply a pleasing note of color in contrast with the cream colored stucco and buff sandstone finish found in the main body of the church. Finally, the regulation Spanish green casings sash bars and grilles, and a gilded weather vane, orb and cross surmounting the towers would complete an effect not only admissible, but pictorially suitable and historically appropriate under the blue sky and in the strong sun light of California.

But all this is lost upon the critic whose next objections are that "the grotesque twisted columns of the front porch are not in scale with the entablature above, and the capping of the dome of the left tower is unfortunate in its profile." Though studiedly unacademic in its proportions, the twisted columns in question do not merit the epithet grotesque. This porch with its round arches, deep reveals, lean-to tile roof, curved gable and unsophisticated bit of architectural finery in the shape of a rather ornate column and capital, etc., is meant to be in every feature reminiscent of the naif spirit seen in the early California Missions. Considering all this, the critics indication of faulty scale, etc., shows more of pedantry than point. Had he known a little more he would have said a little less. The capping to the dome alluded to was changed to what appears above long before it was seen by the *Review*. It was originally in the form of a Font, such as one may see at Santa Barbara Mission and though rather "bossy" and solid quite defensible as a symbolic finial surmounting the roof over a Baptistry.

Concerning the Masonic rather than the religious air, which the design seems to possess according to the critic, he relates an anecdote: "It is said that Renan once happened to enter a church with a companion, and his friend noticed that he removed his hat. 'How is this Renan,' he said 'I thought that you had nothing to do with Mother Church?' 'True' replied Renan, 'but we still have a bowing acquaintance.' If he had seen the church we have just described, it is a question if even this acquaintance would have been justified." The story itself is good enough but desperately *malapropos*. It reminds one forcibly of another story known to most of us. It tells of the man who had just heard a capital gun story, and being at a dinner was dying to recount it. No decent opportunity occurred in the trend of the conversation until a servant let a door close with a mild slam. Instantly our friend started as though he had been shot. "Dear me!" he exclaimed "what a shocking noise, I surely thought there was an explosion! By the way, *talking about explosions* reminds me of an awfully good gun story I heard the other day," etc, etc.



The critic of the *Review* had evidently just heard this Renan story and on no other provocation than the sight of a triangular cartouche over the main entrance, must drag it in to give point to his paragraph at the expense of the architect's design and reputation. For, the architect whose design for a Catholic Church really reminds one of a Masonic Temple is surely as much an ass as the critic who can't distinguish one from the other.

The article concludes with a reference to Design No. 2: "Strangely enough the alternate elevation is a much more attractive building somewhat recalling the early Italian Gothic and showing a good deal of careful study and feeling. The fault most noticeable is the entire lack of cornice to the main tower; the spire rising from the square shaft without any break whatsoever."

It is of course very deplorable that a spire should be made to behave in that way—without any break whatsoever. And far more strange than that a building committee of a second rate parish should adopt the less expensive of two designs submitted, it is that a critic in a first-class review has not written a single paragraph on these designs without making any "break" whatsoever.

The man who sees Masonic Emblems in Catholic Symbols, and an *Early Italian* character in work that is distinctly *Late German* can of course trace resemblances anywhere in any thing. Were he suddenly confronted with a vision of his own precious organ of comparison he would as likely as not be instantly reminded of a parallel of latitude, or a purple cow, or any old thing.

In conclusion he is recommended to let criticism alone, and to devote his unique faculty to tracing the baffling connection said to exist between the Goodwin Sands and Tenterden Church steeple.

GESSO WORK.

OF ALL the fascinating and interesting work that can be accomplished in the home, gesso work is far away in the lead. Already it is exceedingly fashionable. One sees it wherever one goes, as a mural decoration or as an ornamentation to furniture, and it never fails to add an air of elegant comfort to the most unpromising surroundings.

It may not be generally known that many of the art schools are introducing this work as a branch of decorative skill, and it may also come as a surprise that many society men and women are deeply interested in this—the most modern of all arts.

Gesso work has certainly many recommendations. In

the first place, next to no tools are required—all that are necessary being a few hog's hair and camel's hair brushes and a palette knife. Then, again, considering the quality of the work that can be turned out, the material is not so costly as to prevent even those whose pockets are slim from taking it up.

Gesso is made of the best glue and the finest plaster of paris. You put the glue in a jar, and melt it in the usual manner, the jar being placed in a saucepan of water, which is kept at nearly boiling point. Then add the plaster, stirring it carefully, and by drawing the saucepan further from the fire keep it below boiling point, so that the gesso may all get thoroughly heated and mixed without boiling.

Another mode of proceeding is to add scraped whiting to the glue, and to use a little resin, especially if very hardened figures in relief are required.

Both these methods are open to the objection that they are difficult to prepare and somewhat tedious, and learners would do well to avail themselves of the specially made composition that can be obtained at any art store. The difficulty in gesso work is the rapid hardening of the materials, but the composition alluded to is specially prepared and dries slowly, so that more care can be given to the modeling, alterations carried out, etc., as it takes quite half an hour to dry.

Beginners will do well to choose a bold design and to be satisfied with a low relief, and as their hands become more skilled they can attempt something more ambitious. The whole secret of success in gesso work lies in going slowly.

Take for a commencement a panel of wood and give it a coat of green metallic color; when dry, size and varnish it. This is called lacquering. On the green groundwork draw your pattern—a simple scroll, or something easy—then with a brush cover the design with the gesso mixture. Let it dry and give it a second coat. Each coat raises the decoration higher, and you can work up and model the design with the brush while the composition is soft. When dry add a few touches of silver and gold to intensify and bring out the design. Japanese papers will be found useful in supplying suitable designs for the early efforts of the gesso worker. They are generally bold and effective, but not complicated. The learner will find that their birds and flowers can be easily copied. The amateur should bear in mind that gesso work lends itself better to large patterns than to small details.

It will take some practice to perfect the worker in the simple form of gesso work described. When he had succeeded thus far he may attempt the more elaborate patterns.

Having made your drawing on paper copy it on the wood, on which you have laid a thin coat of gesso. You now proceed to work the design in relief with the gesso. You will find that you have to use your palette knife pretty freely in rounding your leaves and flowers.

The breast of a bird would look well done in high relief with fibrous gesso. For this you use cotton wool well pulled into little pieces. Each piece is dipped into a composition made of six parts of size to one of linseed oil. You lay the wool on the design and model it into proper shape. It requires a skilful manipulator to do this successfully, and it is perhaps better for the amateur to content himself with the easier method and produce a higher relief by adding one or more coats of the ordinary gesso mixture. You must let the design dry thoroughly and give it a coat of size if you want the colors you use to come out brightly.

For flowers I should use pale shades of red or pink, because the bird must be gorgeous. His brilliant tail should shine resplendent and this effect is easily attained by using metallic colors. You may on the other hand have a brilliant colored background and make your design in gold and silver. It would be a pity to make a panel all one color, like wood carving, as it would lose so much of the beauty of the spread tail and crest of the bird; but much depends of course on the purpose for which you require it.

There is in fact no end to the variety of changes possible to the succ sful worker in gesso. He has opportunities for modulation of tone, for happy color blending, for originality of design or for successful reproduction of the works of other decorators. Two prosaic facts should be noted—first, that it is well to pour out on the palette only a little at a time of the metallic paint; and second, that when you have finished your work you can clean your palette and brushes with turpentine.—*New York Herald.*

CHANGING FORM OF STONE BY PRESSURE.

[CONTINUED FROM LAST NUMBER]

THE experiments show that limestone and marble, even when dry and at ordinary temperatures, possess a certain degree of plasticity, and can be made to flow, the movements set up developing many structures characteristic of rocks which have been squeezed or folded in the deeper portions of the earth's crust.

It is now the intention of Professors Adams and Nicholson to reproduce more accurately, if possible, the deformation and cataclastic structures of the interior of the earth. For this purpose they have invented an apparatus capable of generating great heat. With this they propose to surround the iron tube, and, by means of steam and heat, obtain those conditions which surround the plastic marble in the bowels of the earth. It has been shown by geologists that marble and other stone foundations become plastic in proportion to the depth they are found in mother earth. Thus, marble found five hundred feet below the surface of the ground is much less brittle than that found, say, at a depth of one hundred feet. The reason for these different degrees of plasticity consists in the fact that the former is subjected to far greater heat and moisture than the latter. By means of their new contrivance Professors Adams and Nicholson are confident that they can reproduce the conditions that prevail far beneath the surface of the earth, and they are awaiting with confidence the results of their future experiments.

PROF. NICHOLSON

The machinery used in all these experiments was designed

and manufactured at McGill, and its counterpart does not exist elsewhere on this continent. It is largely the work of students, who are thus trained in the principles underlying mechanics and hydraulics. The average pressure employed in moulding the marble is 80,000 pounds to the square inch.

THE CYLINDER AFTER FIRST APPLICATION OF PRESSURE.

This is obtained by a number of hydraulic cylinders, which increases the natural pressure of the water mains—130 pounds to the square inch—to the above astounding proportions.

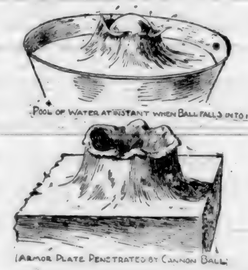
The opinion has been expressed that the experiments suggest a danger from the building of such sky-scrapers as are springing up in our cities. It has been said that if marble, one of the hardest of stones, yields to and becomes plastic under sufficient pressure, then clearly there must be a limit to the height to which one building stone can be heaped upon another in the erection of walls, without incurring the danger of such yielding of the stones of the bottom of the wall or building as will endanger the integrity of a buildihg. For, short of the point at which the stone crumbles, there is apparently a point at which it may slowly change its shape under stress of heavy and long continued pressure.

In reference to the surmise Prof. Nicholson says: "The height of a uniformly thick brick wall required to crush brick work is about one thousand feet, and that of a stone wall to crush either sandstone or limestone about five thousand feet. Long before these heights could be reached the building would have failed from lack of lateral stability under wind pressure, unless the width of base was of similar proportion to the height. Chimneys from five hundred to six hundred feet in height have, it is true, been built, and are still standing, but they have, of course, a regular batter all the way up, reducing the load very much. The crushing pressures assumed by me in my computations on this subject are 800 pounds per square inch for brick work and 4,400 pounds per square inch for sandstone. There is not, therefore, nor can there be any sky-scraper a near approach to the moulding pressures, such as 70,000 to 80,000 pounds per square inch, employed in our experiments at McGill."

COLUMN BEFORE PRESSURE—CYLINDER IN WHICH COLUMN HAS BEEN REDUCED BY PRESSURE AND HAS BURST IRON SHEETING.

Another interesting question on which new light is thrown by this experiment is the perplexing one of the motion of the glaciers. As everybody knows a glacier is in effect a great river of solid ice. It is equally well known that the ice stream flows along its channel, slowly, to be sure, but just as surely as a stream of water. The early students of glaciers doubted this, but numberless careful observations, culminating with the famous ones of Professor Tyndall, have demonstrated the point beyond all controversy. Of course the bed of the ice stream is usually steep, and hence at first sight it seems nothing remarkable that the ice should slide along it. So the famous explorer of the Alps, de Sanssure, who was among the first to recognize the motion of glaciers, explained this motion as a mere sliding of the ice. Very soon, however, other observers saw that this simple explanation by no means sufficed, for the most casual observation showed that the channel through which the glacier moves—its banks or borders—is not usually of uniform width from beginning to end, but, on the contrary, widens and narrows as does the channels of a river. And, like the river of water, this river of ice at all times completely fills its channel, spreading out into lagoons of ice where the channel widens and narrowing into a slender stream as the walls contract. Clearly, then, the ice stream changes its shape just as the stream of water does; yet how is this possible, since ice is a solid, and a very brittle solid at that?

Numberless explanations have been put forward in elucidation of this puzzle, but the one that has seemed to have greatest plausibility and hence has gained greatest currency assumes that the ice in the depths of the glacier is being constantly melted by the pressure of the mass above it, and is constantly recongealed, being molded into new forms during the moment of transition. The justification for this hypothesis is found in the fact which was demonstrated by Professor James Thomson, the brother of Lord Kelvin, that pressure, if sufficient, greatly lowers the melting point of ice; if cut into and broken into fragments will recongeal into one mass if the parts are kept in contact. It was pointed out by the Scotch geologist and mathematician, Dr. Croll, that the sun's rays, beating upon the surface of the glacier, might penetrate into its transparent depths, and, being retarded at the bottom, might heat the ice at a depth to a temperature above that at the surface and this cause would manifestly act in conjunction with the increased pressure at the bottom of the glacier, to effect the melting of the ice there. At no time, however, would there be any great surplus of heat there and the portions of ice thus melted would be certain to recongeal almost instantly, because of the large quantity of heat which is abstracted and rendered latent whenever ice changes into water. But during the instant of transition from ice to water and back to ice again, the particles of the mass might slightly change their form, under influence of pressure and of gravitation; and thus by an endless series of infinitesimal jerks, as it were, the glacier would creep on as it is observed to do.



Now, however, the experiments regarding the mobility of marble put quite a new complexion upon the question of glacial movement. For if it be proved that marble, a substance far harder than ice, and quite as brittle, can be molded by pressure alone into new shape, it seems perfectly plausible that a much less degree of pressure might mold ice into new forms by causing its molecules to slide over one another without the intervention of melting. In this view ice and marble, and, of course, all other solids, are to be regarded as merely very stiff or viscid liquids. Gravitation alone does not suffice to make them flow, as it does more limpid liquids, but when additional force is applied their mobility becomes apparent.

This view, indeed, as applied to such solids as iron and other malleable metals is not new, for the mobility of such solids under pressure, as when hammered, is widely known. A curious experiment recently made by Prosessor Sinclair

has illustrated this in a very vivid way. By means of an ingenious apparatus it has been possible to photograph the surface of a bowl of water at the moment a ball dropped from a height falls into it. The photograph being instantaneous, the water splashed up about the ball gives the impression of a solid crater. But the curious feature is, that exactly such crater as this is formed into a sheet of armor plate. About the mouth of the hole where the ball enters the iron is a bulging rim or crater of iron, which was manifestly splashed up exactly as the water splashes up about the miniature ball, making the observer feel that the iron and the water are really of one physical nature, one being merely a little harder than the other. The experiments at McGill make it clear that the same thing is true of marble also; that, in short, in a broader view, brittle solids are only very fragile liquids, just as malleable solids are very tenacious liquids. Perhaps some day we may mould our statuary out of marble instead of slowly carving it, as is now done.—*Stone.*

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

VALUABLE INFORMATION CULLED FROM OUR EXCHANGES.

THE supreme court of Montana last week declared valid the contract between Bell & Kent, architects (formerly of Council Bluffs, Iowa, but now of Helena), and the Montana capitol building commission. The supreme coart denied the petition of several competing architects for a writ prohibiting the architects to whom the plans were awarded from proceeding with the work. As previously mentioned in these columns, the Montana law required the capitol architects to be citizens of the state, and the petitioning architects claimed that Bell & Kent, the successful bidders, did not meet the requirements of the law. The suit developed that Bell & Kent came to the state on March 18 and entered into a contract with the capitol building commission March 20. The court held that they had established a residence with bona find intentions and in good faith, and refused to grant the injunction. The decision will permit work on the $275,000 capitol building to be commenced next fall.—*The Construction News.*

CONSIDERABLE agitation has been going on at Washington, D. C., over the height of buildings in general and in particular over the height of apartment buildings on residence streets. A bill has been introduced in the house of representatives to reduce the building limit, and the interpretation of the word "avenues" in the building ordinances is the subject of much contention between the commissioners and the builders of a proposed apartment house, 110 feet in height, on Sixteenth near K street. The building regulations provide that in no case shall a building exceed ninety feet in height on a residence street, nor 110 feet on a business street, "except on avenues 160 feet wide," where a height of 130 feet is allowed. The word "avenues," the owner contended, meant a thoroughfare, in the connection in which it was used in the building regulations, whether that thoroughfare happens to be designed in street nomenclature as avenue or street. The building commissioners refused to grant a permit for the building, and the builders filed an application for a mandamus to compel the commissioners to issue a permit to the complainant. Judge Cole denied the writ of mandamus on the ground that it was the intention of the ordinance to restrict buildings on all residence streets to a height of 90 feet. This decision is likely to be frequently cited as a precedent in future cases.—*The Construction News.*

IN St. Augustine's Church, Brooklyn, N. Y., the tabernacle of the high alter is protected by probably the most novel safe ever devised. This is undoubtedly the first time in which practical science has been used as an adjunct in religious service. Of course, it was very essential that the beautiful alter itself should not be marred in any way by the safe and that it should be operated in a dignified and fitting manner. Unfortunately, in many churches, the richly jeweled receptacle for the sacrament has proved too often a bait for burglars, and many priests have tried to devise some scheme by which the security and sanctity of the tabernacle would be assured.

In the church to which we have referred the receptacle for the sacrament cost $10,000. The safe consists of circular curving doors which slide together, closing the front toward the church. The safe weighs 1,600 pounds and consists of four pieces, the base, a curving piece of steel at the back that is stationary and the two doors which come together. The leaves of these doors are made of Harveyized steel an inch thick. They meet as they close under the dome and overlap each other tightly by a scarf joint. They turn on

roller bearings and they are operated by means of an electric motor. The safe is easily opened by manipulating buttons beside the tabernacle, but these push buttons will have no effect until the motor itself is set in motion in the vault below, the combination lock of the steel vault being known only to the priests of the parish. Electrical protection is also provided which would give notice at once to the nearest police station should the safe be tampered with. Masked in its covering of gold leaf, this steel shell is a superb piece of mechanism and is one of the most ingenious uses to which the electric motor has even been put. The same motor is used to drive a blower intended for the purpose of dusting the elaborately carved marble altar. An exhaust fan sucks away the dust.—*Scientific American*.

THE ACTION OF SEA-WATER UPON HYDRAULIC CEMENTS.

BY DR. WILHELM MICHAELIS — TRANSLATED AND ABSTRACTED BY WALTER FRANCIS REID.

From Proceedings of the Institute of Civil Engineers [England] Vol. CXXIX.

WHEN a saturated solution of lime acts upon the combined hydrates of silica, compounds of ferric oxide and alumina are formed, containing respectively 3, 4 and 5 molecules of lime to 2 of the oxides, and these compounds are united with water in such proportion that at least 1 equivalent of water is combined with 1 equivalent of lime. Hydraulic cements rich in lime must, therefore, during the hardening process, segregate the lime as hydrate. In Portland cement the hardened mass is completely permeated with crystals of calcic hydrate. The hydrate of the combined aluminate and sulphate of lime ($Al^2O_3, 3CaO + 3CaOSO_3 + 30H_2O$) has been observed when the compound was dried over sulphuric acid, and the following calculations are based upon this proportion of water, although in practice it must be far greater. Each molecule of alumina present in hydraulic mortar as the hydro-aluminate of lime can form about 12 parts of this double salt, and the hydro-ferrate of lime acts in the same way. The true Roman cements, containing 1 part by weight of silicate to 1.1 to 1.2 parts by weight of lime, are, from the chemical point of view, the best hydraulic mortars, because, during the hardening process, they form the most stable compounds, without unsaturated seridues. Such cements are, however, burnt at so low a temperature that they are deficient in density, so that mortars made with them shrink considerably when exposed to the air through the evaporation of the water which they have absorbed. All water exceeding in quantity that required for the formation of calcic hydrate must be considered as water of expansion and is very loosely combined. Hydraulic limes, such as that of Teil, bear a close resemblance to Roman cements, but are even looser in texture. Of the 68.6 per cent of lime in Teil lime, 36.48 per cent only would combine with the other constituents during the setting process, leaving 32.12 per cent of lime in an uncombined state.

Portland cement, having been burnt at a higher temperature, is denser than Roman cement in the ratio of 5 to 3; but from the chemical point of view this cement is also defective, because, even supposing the richest calcareous compounks are produced during the setting process, there still remains an excess of uncombined lime. A Portland cement containing 61.04 per cent of lime would leave 13.79 per cent of lime unsaturated, while one containing 68.379 per cent would leave a similar residue of 29.1 per cent. In the case of a Portland cement of averoge composition, with 1 part of silicate to 2 parts of lime, 25 per cent of lime or 33 per cent of calcic hydrate would be segregated.

A body containing a substance of such strong chemical affinity as free lime cannot be regarded as stable. The free lime will continue to react until it forms a saturated compound. When the mortar hardens in the air or in water containing carbonic acid, the lime is converted into carbonate; but in sea-water it is chiefly the sulphates which act upon the lime. In the first instance it is the free lime that is converted into carbonate or sulphate, then the very unstable compound with ferric oxide, then the aluminate, and finally the silicate. The formation of the sulphate with two equivalents of water causes a considerable increase of volume, and may destroy the cohesion of the mass. With this formation of gypsum the production of lime aluminate-sulphate goes hand in hand, and this causes an enormous increase of volume, and a total destruction of the cohesion, for this double compound crystallizes with at least thirty, probably sixty, equivalents of water, and in doing so converts the strongest mortar into a mud, the only part of which retaining any cohesion being those protected by the formation of carbonate. Good Roman cements resist the action of sea-water well because they only contain enough sulphate of lime to form sixteen parts of the double salt which finds sufficient space for expansion in the pores of the mortar. In such hydraulic limes as that of Teil there is little alumina, and consequently the chief increase of volume is due to the formation of calcic sulphate and not to the double salt. One of the reasons why Teil hydraulic lime has proved more successful for marine work than Portland cement is that the blocks made with it are allowed to harden in the air for a long time before immersion, while Portland cement is generally exposed to the action of the sea-water at once. Even if Portland cement concrete blocks be exposed to the air until a protective skin of carbonate of lime is formed, such a skin cannot attain any considerable thickness, and the chemical reactions to which the destruction of the cohesion must be attributed will eventually take place. In order to ascertain the action of carbonic acid and sea-water upon the strength of Portland cement, a series of experiments were carried out. Two sets of briquettes were made according to the German standard rules, one composed of one part by weight of Portland cement to three parts by weight of standard sand, and the other of one part cement to five parts of standard sand. These briquettes were allowed to harden for twenty-four hours in the air, but protected from carbonic acid, and were then placed in boiled distilled water for 56 days, the vessel in which they were kept being hermetically closed. Half of the briquettes were then treated with moist carbonic acid for five weeks, and were finally returned to the closed vessels, in which they remained four weeks longer. When tested, the briquettes were therefore 120 days old. The 1:3 mortar protected from carbonic acid gave a tensile strength of 26.9 kilos per square centimeter, while the briquettes treated with that gas gave 28.5 kilograms per square centimeter (405.3 pounds per square inch). The crushing

strength was 309 kilograms per square centimeter in the first case and 338 kilograme per square centimeter (4,806.3 pounds per square inch) in the second. The 1:5 mortar protected from carbonic acid broke at a tensile strain of 14 kilograms per square centimeter (199 pounds per square inch), and, treated with carbonic acid, the strength increased to 16.8 kilograms per square centimeter (238.9 pounds per square inch). The crushing tests gave 112 and 138 kilograms per squate centimeter (1,592.6 and 1,962 pounds per square inch) respectively.

To be Coutinued.

SEMI-ANNUAL SUMMARY OF BUILDING OPERATIONS.

IN the following tables we present the number and value of buildings erected in San Francisco during the first six months, it will be noticed that there is an increase in the amount of cost as compared with the first six months of last year while the number of buildings is much less.

FOR FIRST SIX MONTHS. 1898.

1898	No. of Building Permits.	No. of Contracts.	Brick Building Value.	No. of Building Permits.	No. of Contracts.	Frame Building Value.	No. of Building Permits.	No. of Contracts.	Alterations & Additions Value.	No. of Building Permits.	No. of Contracts.	Total Value.
Jan'ry	3	4	$ 58,901	19	14	$ 81,286	7	7	$ 27,338	29	25	$ 167,525
Feb'ry	6	10	92,829	15	17	62,981	6	13	33,380	27	40	189,143
March	3	7	77,154	39	37	215,382	11	13	51,870	53	57	346,406
April	3	15	165,301	33	38	139,221	16	19	119,894	52	72	424,415
May	4	12	151,108	19	23	67,980	9	15	41,815	32	50	260,903
June	8	20	313,984	28	42	157,476	14	18	62,156	10	80	533,616
Total	27	68	$ 859,307	153	171	$ 726,329	63	85	$336,650	233	324	$1,922,286

To this amount has been added the further estimated sum of $300,000 where costs have not been given, which would make the grand total for the year, $2,222,286.

FOR FIRST SIX MONTHS.—1897.

1897	No. of Building Permits.	No. of Contracts.	Brick Building Value.	No. of Building Permits.	No. of Contracts.	Frame Building Value.	No. of Building Permits.	No. of Contracts.	Alterations & Additions Value.	No. of Building Permits.	No. of Contracts.	Total Value.

ANOTHER BUILDING DISASTER.

FOLLOWING close in the train of the recent building disaster at London, Ont., with its terrible consequences, comes the news of the collapse on February 21, of the roof of a large music hall at Oshawa, Ont. The building is described as a three-story brick structure, with a large assembly hall on the upper floor. It was covered by a flat roof about 75x100 feet in size, which fell to the second floor, completely covering the seats in the music hall. The accident occured at five o'clock in the morning. To this fortunate circumstance is due the fact that a number of lives were not sacrificed. On the preceding Saturday evening a large political meeting was helded in the building, and on the evening of the day on which the accident took place an entertainment was to have been given at which it was estimated there would have been present 800 persons. How terrible, therefore, would have been the consequences had the accident been delayed but a few hours! Doubtless the immediate cause of the collapse was accumulation of snow on the roof, but the fact that the roof was a new one and that the building had recently undergone changes and repairs, at a cost of about $5,000, is sufficient proof of structural weakness. These accidents unmistakably affirm the necessity of a standard of qualification on the part of those who undertake to design and erect buildings—particularly those of a public character. If the title Architect was restricted to persons who had passed a qualifying examination, as is now the case in the province of Quebec and the State of Illinois, the public would at least be enabled to know who were qualified to put up safe structures, and could then govern themselves accordingly. Under present circumstances anybody is at liberty to call himself an architect and to design and erect buildings of every class. So long as this condition of things shall continue, accidents involving injury and loss of life will be the inevitable consequence.—*The Canadian Architect and Builder.*

BURNT CLAY HAS AN INNINGS.

NEW YORK, N. Y., July 15, 1898.

To the Editor of the California Architect and Building News,

SIR:—We have again to thank you for a copy of your interesting paper of May. It seems to us that the question at issue is primarily: "which is the best material for fireproofing purposes—burnt clay or concrete?" and the solution of this is within the reach of any one. Let him procure a piece of porous terra-cotta and one of cinder concrete such as is used in buildings; place both in any kitchen range; the

when heated red-hot, drop into a bucket of water and noting the result, from his own judgment.

To hold the material responsible for faulty construction such as is shown in your illustrations of the Park Row building in this city, is simply ridiculous; through an agreement entered into some time since between the master builders and unions, the manufacturer of hollow tile is debarred from getting any of his material in New York City, whilst the manufacturers of concrete control the entire operation from first to last.

Give the manufacturer of hollow tile equal privilege to erect his material, grant him at same time leeway to supply any petty deficiencies in the general fireproofing which his experience teaches him is vital and you will secure a structure as thoroughly impervious to fire as the present appliances of science furnishes—and thereby demonstrate clearly what is possible in fireproof construction of burnt clay when unhampered by other considerations than that of perfect efficiency.

The same authority that procured those illustrations could easily satisfy himself that the material is delivered in good condition at the building and that all blame for defective construction and broken tiles rests not with the manufacturer, who deplores, being vitally interested far more than *Engineering News*, such miserable work as you show.

And yet, despite defective setting, which *Engineering News* claims is almost universal in fireproof buildings constructed of hollow tile in New York City, such buildings have withstood the fiercest internal fires with little or no damage; and the Pittsburg fire so demonstrated, Mr. Jenny to the contrary notwithstanding.

If the Firewriters Association of the N. W., desire information as to the best fireproof construction for buildings, it could procure such based on actual experiences, by applying to the New York Board of Fire Underwriters.

A progressive manufacturer of burnt clay fireproofing aims to profit by the lessons which past experiences have taught him; to incorporate in its manufacture every improvement suggested by thoughtful ingenuity and unceasing experiments, but, "there are others".

The other systems of fireproofing which have sprung into recent existence from their very novelty, are limited in practical application to actual building operations and have thereby escaped so far any test of their efficiency in the light of subjection to actual conflagration. We know what to expect of a material which in its manufacture is exposed to a temperature of fully 3000 degrees Fahrenheit, and we have seen its conduct under subsequent fires in numerous instances, but what will result when the newer systems are called upon to prove their claims?

We have a report to the National Fire Protection Association of Boston on a fire of April 2, 1898, No. 278-288 Congress street. "Floors concrete, (Columbian construction). Cause of fire probably spontaneous combustion in the outside surface of three barrels. Did not burn through barrels and floor not scorched. Damage caused by fire starting a Grinnel Sprinkler, which was not discovered by watchman in time."

"The floors which were supposed to be water-proof, allowed water to run through and caused damage in four stories. The action of lime (in concrete) with water, passing through caused silver plated ware to be turned black, necessitating replating and polishing."

As unslaked lime, one of the essential elements of cement and therefore in concrete, is not only a conductor but one of the greatest known absorbents of moisture, electricity will find its way through any moisture, containing material. The concrete system applied in a moist condition, retains its moisture for a more or less extended period and in these days of ever extending electrical appliances in our steel-frame buildings, the danger to that metal of electrolysis is one that is attracting the earnest attention of our Architects and one to be well considered. Hollow tile, on the contrary, is a perfect non-conductor and is absolutely dry when laid.

Yours truly,

HENRY MAURER & SON.

THE CONTINENTAL FIRE INS. CO.'S ARCHITECTURAL BOOMERANG.

Editor California Architect and Building News.

DEAR SIR:—With your permission I desire to draw the attention of Architects to an announcement in the June number of the *Coast Review*, which states that the Continental Fire Insurance Company of New York has published a work containing plans and specifications of economical buildings, etc., a copy of which the company will send to any property owner desiring to build, if the said owner "will insure with the Continental."

This is a new departure, for a respectable corporation to take, but quite in keeping with the "beautiful present" or "something for nothing" idea so prevalent in these days among certain storekeepers.

How the Continental of New York, expects to be benefited in the long run by adopting these tacties is left to conjecture.

Fortunately Architects (and their clients) still have plenty of choice left in the matter of insuring their buildings, and with companies who do not offer plans and specifications as an inducement to obtain premiums and they still have sufficient intelligence left to exercise it.

The publication referred to is also said to contain (for the owners benefit of course) blanks for contracts with builders and "architects". I can only say that if these contracts are of the New York Standard policy type—"ironclad" and duly Harveyized—they would be as useless to an owner, as the said plans and specifications would probably be.

Yours respectfully,

ARCHITECT.

IRON SHUTTERS VS. WOOD SHUTTERS.

NEW YORK, July 13, 1898.

To the Editor of the California Architect and Building News.

DEAR SIR:—In the June number of your Journal I read an article on "Iron Shutters" in which it states that the Fire Department of New York City has lost faith in iron shutters, and that a wood shutter lined with tin is the best shutter in the market today, known as the "Underwriter's Shutter" by the Department.

As one who has been in the business of manufacturing and erecting fire-proof shutters all over this country for twenty years and more, who makes a specialty of shutters, seeing

the ridiculousness of such a claim I take the liberty to write these few words.

If the comparison is made by Chief Bonner between common folded wire shutters and wood lined with tin, I agree with him, as common iron shutters will burst open in thirty minutes under an intense heat—I suppose this is what the Chief had in mind.

In 1886 a large building was erected in Chicago, Ill., designed by the late Mr. Richardson, the Architect, and who took special interest in the shutter question for that building. He selected a shutter which I saw placed in that building in round numbers, seven hundred and fifty in all.

Some six years after the said building was finished, I had a call to put in more shutters for this same concern. In my conversation with the Chief Engineer I asked him "how did the shutters wear in the old building?" His reply was this: "Two years ago we had a terrible fire across the street, burned the whole block and part of another, the shutters you put in were white with heat, then we placed our water on them from the inside as an experiment in our excitment, the shutters had room to expand in the channels and when the fire was all over we had only the painting to do on the shutters."

The above rolling steel shutter was invented by Clark, Bunnet & Co., London.

Yours very respectfully,
J. D. Thomas, Supt., N. Y.

THE SURVIVAL OF THE FITTEST.

IT WAS Herbert Spencer who, when seeking to define his views, touching the Status of man, and the lower animals, in the visible universe, coined the above axiomistic phrase. This sententious deliverance of the great biologist, has long since abundantly justified the claim that

"Many a shaft at random sent
Finds mark the archer 'little meant'."

in that it has been found—or made—to fit conditions its promulgator scarcely contemplated. With our characteristic tendancy to exalt the apposite, we do not hesitate to utilize terms well befitting a "bacillus" to exploit a—well, say for instance—a boiler, or to be quite explicit "A Copper Range Boiler."

If in preparation of plumbing Specifications, wherein the best goods obtainable, are demanded, architects would call for the "Brown Bros. Seamless Drawn Copper Range Boiler, they will certainly obtain what they seek, whereas the words "or e ual' added to the specifications, will most certainly defeat the intention and provide an easy path for "the substitution evil.

This seemless drawn boiler is made of two solid seamless shells cold-drawn from pure Lake Copper and has no brazed seams or rivets. It has successfully withstood the test that tries all things—"time"—and is fully guaranteed by its makers not to collapse.

Architects will find that the experimental element does not enter into the "Brown," and he has the positive assurance that in this boiler, he is giving his client the very best article of its class in ex istance.

FOR STEEL CONSTRUCTION.

THE new building for the Wells, Fargo & Co's., Express consumed nearly 1000 tons of steel in the skeleton structure. To prevent corrosion to this vast amount of metal, covered and fireproofed, as most of it will be with layers of concrete, the architects gave the preference to Dixon's Silica-Graphite Paint.

CABOT'S SHINGLE STAINS.

THOSE who required further evidence of the value of Cabot's Creosote Shingle Stains in this climate will find it in the brochure just issued from the office of the San Francisco agent, Mr Charles J. Waterhouse, 421 Market street. This little book, which is illustrated with half-tones and line sketches of a number of handsome country-houses that have been actually stained with these Stains, contains also the testimony of architects and owners all through this section of their complete satisfaction with the coloring effects, preserving properties and durability of the Creosote Stains. Being in the wood, and not wholly on the surface like paints, they cannot crack or peel off, as paints do, which is a very important advantage in this climate, but perhaps their most unique advantage here is the fact that redwood shingles treated with them never turn black, as they always do otherwise. Mr. Waterhouse carries a full stock here, and Mr. P. H. Mathews, 238 South Main street, is Los Angeles agent.

ROOFING OF WELLS FARGO & CO.'S BUILDING.

The Paraffine Paint Company have the contract for the roofing work and roofing material on the Wells Fargo & Co.'s new building, and the roof is row well in hand.

GOOD LOCKS.

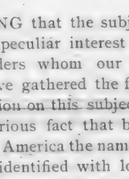
SOME INTERESTING FACTS ABOUT A FAMOUS LOCK. THE PRINCIPLE AS OLD AS THE PYRAMIDS AND MODERN AS THE CENTURY.

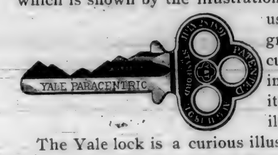
BELIEVING that the subject of locks has a peculiar interest to the class of readers whom our pages reach, we have gathered the following information on this subject:

It is a curious fact that both in England and America the name most prominently identified with locks is that of an American; in the former, that of A. C. Hobbs, and in the latter, that of Linus Yale, Jr.

While the makers of the Yale lock, The Yale & Towne Mfg. Co., of 84–86 Chambers street, New York, have associated the trade name "Yale" with many of their finer products, in connection with locks it can only properly be applied to the original invention of Mr. Yale and to the later improvments thereon which have been developed and introduced since his death by the Company.

The essential characteristics of the Yale system are shown in the accompanying illustrations, and consist in the separation of the key and tumbler mechanism from that of the bolt mechanism, and in the adaptation of a key of sheet metal to the actuation of the peculiar tumbler mechanism shown. The original Yale lock had a perfectly flat, thin key, which was the forerunner of the innumerable forms of flat key now so generally used. It is a common mistake to characterise any lock with a flat key as a "Yale Lock", and many persons are thus misled. The flat key was an incident in Mr. Yale's invention, but its chief importance lies in the form of tumbler mechanism adopted, the vast capacity for key changes which this affords, and the resulting immunity from liability to accidental interchange of keys. In common locks the key changes are counted by the dozen only; in the Yale lock they are counted by the thousand. The flat, steel key of the original Yale lock gave place later to the corrugated key, and this in turn to the latest from, the "Paracentric," which is shown by the illustration. The peculiar key-way used with the latter adds greatly to the original security of the lock, while the intricate form of the key itself practically precludes illicit duplication.





The Yale lock is a curious illustration of the adage that "there is nothing new under the sun". In the pyramids of Egypt locks have been found embodying the pin-tumbler system. Here, however, the resemblance ends. In the application of the principle, and in all refinements of mechanical detail, the difference is as wide as that between the civilization of Egypt under the Ptolomies and that of America at the close of the nineteenth century.

THE KEELY MOTOR UP-TO-DATE.

PROCEEDINGS OF ENGINEERS' CLUB OF PHILADELPHIA.

BY E. J. SCOTT, ACTIVE MEMBER.

CONTINUED FROM JUNE NUMBER.

THE VISITOR also saw the engine built to navigate an airship, recently described in a city journal as a new invention. He saw the engine, afterwards called a "Vibrodyne," which was to revolutionize all commercial machinery. This was not shown in operation. Keely also showed him a large book for the purpose explaining the principles of his vibratory philosophy. It was filled with heavy cardboard leaves, covered with pen drawings, all made by Keely with beautiful exactness. Nearly every one of the plates had one or more bars of music, showing the dominant chords or vibrations which governed certain combinations. The inscription on the Zuni tablets would have been quite as plain to the visitor, and Mr. Keely kindly enlightened him as to their meaning. In explanation of one of the simpler charts, Mr. Keely said: "The chord of polar negative attraction, so far as this sympathetic research is concerned, proves conclusively that the chord of theneutral center of the polar attractive currents of the earth represents the sympathetic chord of B flat, third octave, one-hundredth of a note below the octave, according to sympathetic sub-division."

The visitor had before noted that Keely's language, while sounding perfectly familiar so far as the words were concerned, did not convey any ideas. He soon learned that without a knowledge of the application made by Keely of the terms which fell so glibly from his tongue it would be useless to study the subject by question and answer. Some months afterwards he was given some manuscript of Keely's which was said to be the clearest exposition of his views on the great vibratory principle upon which his discovery is based. The first paragraph of this paper, which serves as the introduction to the subject, reads thus:

"The peculiar sympathetic conditions whereby a magnet is conserved to polar and anti-polar currents of the earth show a duality of sympathetic inflow and outflow as to prove anything but perfect sympathetic equations, as between its reception and distribution in that part of the electrical field that represents one of the triplets that in celestial physics is classified as inter-atomic vibratory oscillation. Now, if this oscillation represents in its alternating action a vibratory wave-motion representing in its corpuscular field of action, say 128,400 exchanges per second between polar reception and anti-polar (or depolar) distribution (which sympathetic philosophy proves most conclusively), the fact is established of its perfect sympathetic concordance to that third of the electrical triplet representing the sixths as classified in sympathetic physics, and thus that line of sympathetic action as represented in the magnet when it is electrically sensitized becomes thoroughly subserved to polar sympathetic attraction as a medium through which a portion of a polar flow is diverted—not latent, but highly active under all conditions as long as its sensitization exists—that is its magnetic sympathy as electrically induced, and associates itself with every medium in nature where this latent element exists, viz: steel, iron, oxygen at a low temperature, etc."

As Keely has made vibratory physics the study of his life, it will be taken for granted that the statement just quoted is authoritative. At the same time the writer confesses that he does not understand it, although it sounds all right.

Mr. Scott left with the understanding that the should make a second visit at some date to be named. In the meantime he discussed the details of what he had witnessed with Mr. Addison B. Burk, President of the Spring Garden Institute, who agreed with him in some of his conclusions, and it was arranged that both would be present at the next visit to Keely, if agreeable to Mrs. Moore. That lady gave her consent, and named November 23, 1892, as the date. It was arranged between them that if the experiments was repeated, each would pay attention to certain details, so as to cover as many points as possible. At this visit the surroundings of the place and arrangement of the rooms constituting the laboratory were noted.

Entrance is made from the street through a large door into a room in which is a carpenter's workbench, some powerful winches, and an assortment of tools; and on one side was an immense box, bound with iron bands, with a cover so heavy that tackle was arranged above it for lifting it. It was closed and padlocked, and was said to contain machinery not now in use. A large door led into a room on the same floor at the rear of the first one, which was not opened on any of the visits. A stairway to the second floor leads to a landing on which are parts of abandoned machinery. A small room on one side of this contains a large desk, with books, instruments and drawings. On the opposite side of the landing is a room somewhat larger, with many expensive looking instruments, or machines, some of which he exhibited in operation. Back of both of these rooms is a large room the full width of the house, in which some of the apparatus was exhibited. To the rear of this is another room, a step or two higher. This last room is over the back room on the first floor, before referred to. To the north of this building is the central power station of the Columbia Electric Light Company.

One fact which may or may not be of importance, in con-

nection with all the visits, is that Keely required of Mrs. Moore twenty-four hours' notice of any visit at which exhibitions were to be made. On the second visit, at which Mr. Burk was present, Keely was asked to show the sensitized round steel bar before referred to. He produced it, and a measurement showed it to be 7½ inches long and 1 1-16 inches in diameter, with a small hole through it longitudinally which could be blown through but no light would pass through it; another larger hole was bored through the bar near one end. By striking it on the floor with one end, it would vibrate with a base note like an organ tone which would continue for more than a minute; a blow on the other end produced a note of high pitch not quite so persistent. Keely's explanation of this phenomenon made at the first visit, was that the bar had been "vitalized" and its proportions had been calculated to a nicety. His exact explanation was: "By vitalizing this bar it produces a molecular oscillation of three times the diameter of the molecule, whereas under ordinary circumstances with a piece of forged steel, the oscillation is only one-third of its diameter, 40,000 times a second, which is perfectly inaudible to the ear. By increasing the magnitude of the vibrations by the sensitizing process to three times the diameter, it gives a molecular swing that brings out an oscillation that produces a chord with three different notes."

Mr. Scott had formed a different theory and asked that the bar be weighed. At just this junction Mr. Keely admitted a caller, a young man with whom he appeared to be well acquainted, and having no scales in his laboratory, he asked the young man to take the bar to a neighboring drug store and have it weighed. He returned, saying its weight was 3 pounds, 3 ounces. During his absence Keely explained that the sensitizing process consisted in treating the metal with hydrogen in an oven, which would sometimes reduce its weight to nearly half the normal. Making allowances for the rounded ends, the bar had evidently suffered a loss in weight, but not in that proportion. Mrs. Moore told the writer that the bar had created a sensation among scientific gentlemen in Europe, and that there was a standing offer of $10,000 for the production of a similar bar.

To test the truth of this theory and not in the hope of reward, the investigators concluded to have a bar made. After several attempts with vibrating single bars inserted in a bored-out piece of steel, Mr. Burk succeeded in having an exceedingly good imitation made at the Spring Garden Institute, by inserting two ordinary tuning forks of different pitches in the bored-out steel, and concealing the work by screwing on an end piece and then turning the bar off in a lathe. It required more work, probably, than the hydrogen process, but the molecules had the requisite swing, and the notes the proper resonance and persistence. This simply shows that there is possibly more than one way of arriving at the same result. After the duplication of this bar, the original could not be seen.

Mr. Keely on this occasion showed his apparatus for sensitizing bars, and also the amalgam disks which form so conspicuous a feature in all his apparatus. It was a glass receiver, from which the air could be exhausted by an air-pump, with an opening at the bottom large enough to admit the object to be sensitized, which must be mounted on glass. The opening was closed with a screw cap. The objects to be treated must not be touched by the hand, as by so doing vibrations might be set up in the body which would defeat the purpose. When the treatment was completed the disks could be handled without detriment.

The disks referred to were about 2½ or 3 inches in diameter, of brass, and an inch thick, with the center turned out, making it like a cap, or cover of a jar. The cap was then filled with an amalgam and finished off smooth, like the obverse brass face of the disk. Keely said the composition of this amalgam had cost him some years of study. It melts at so low a temperature that he had caused much amusement by having spoons made of it, which when put into a cup of hot coffee would melt and disappear. The brass face of the disk was gold plated, which Keely said was essential.

On this visit the levitation experiment was exhibited again. The apparatus consisted of a cylindrical glass jar 41 inches high and about 10 inches in diameter. It was closed hermetically with a cap extending down the sides at least two inches. It was filled with what Keely said was pure water. On the bottom of the jar was one of the disks before described, standing on edge, also a globe covered with gold leaf about the size of an orange, with a small cylindrical projection on one side on which it rested. Keely said the globe was filled with shot. This jar stood on a small pine table upon a thick sheet of glass. In the cap of the jar Keely said there were copper and platinum strips which were responsive to certain vibrations. On the table near the jar he placed what he called a "Sympathetic Negative Transmitter," and connected this with a thumb-screw on the cap of the jar by a platinum wire. This transmitter was a large brass ball about eight inches in diameter, from one side of which protruded a straight cylindrical handle, or bar, which, by turning one way or the other, was projected into or drawn out of the ball. The movements resembled those made in operating the combination of a safe. On the outside of the ball was a small horn formed of a tube of increasing diameter, coiled with its large end outside. Also three small disks of metal into the circumference of which spines of metal of various length were inserted, forming a scale of tones when snapped. One was the diatonic scale, one harmonic, and one attuned to fifths.

Keely then placed a sensitized disk on top of the jar, and another at its base. He explained that the disks and the objects inside the jar were in sympathy with each other, and that it was essential thus to place them. Then turning the knob or handle of his transmitter a few times, as if to adjust it, he snapped the spines on the scales at different points, and soon the weights at the bottom of the jar began to quiver; the disk started slowly upward, followed by the shotted weight, and with a slow, uniform motion they rose to the surface and bumped against the cap, bobbing up and down until they came to rest. The disk, which started first, moved faster than the globe. Keely explained that this was due to the difference in the rates of vibration of their chords of mass. This difference was 120 per minute, and he could, with care, make one ascend while the other descended or remained at the bottom. He played a few notes on a mouth-organ, disconnected the platinum wire from the jar and said the weights would remain at the top indefinitely. The jar was left while the visitors looked at other apparatus, and after a time they were found still on the top. Keely connected the transmitter and jar again by the wire, struck some chords, and the weights descended. He played a chord softly on the mouth-organ, repeating it at short intervals, and both started to rise; using the handle of the transmitter and changing the chord after they had risen three or four inches, the shotted ball dropped to the bottom while the disk continued to the top.

To be Continued.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

BUILDING NEWS.

Three-story hospital to be erected on east line of road leading to Reichert's house; o, Fred Finch Orphanage; a, Geo. A. Wright; c, Ingerson & Gor.; cost $4475.

Pleasant and Fruitvale Ave. Carpenter; o, W. O. Ralston; a, W. F. Smith; c, D. S. Brehaut; cost $3425.

MILL VALLEY

Lot 28, Tamalpais Land Co. To build; o, J. Fred Schlingman; a, Edgar A. Mathews; c, Andrew S Ruch; cost $485.

PALO ALTO

On grounds of the Leland Stanford, Jr. Stone work etc; o Mrs. Jane L. Stanford; a, Percy & Hamilton; c, McGilvray Stone Co; signed, June 12; filed, July 14; cost $70,380.

PROSSER, WASH.

J. B. Cape is having plans prepared for an hotel building.

POMONA

L. W. Pierce has plans ready for his new house, which will cost $3500 to $4000. It will be located at the old home place on Pasadena street, the old house having been moved to Gibbs street, south of Pasadena. Ferdinand Davis is the architect, and informs us that the house will have somewhat the appearance of Miss Becker's new house on West Holt.

PASADENA

Architect R. B. Young has prepared plans for the new St. Andrews church of Pasadena. The building will cover an area of 60x130 feet, with a seating capacity of 700. It will be of pressed brick with stone basement and slate or metal tile roof. The architecture is of the Romanesque style, and will be a picture of architectural beauty.

SAN JOSE

Seventh and San Salvador. Two frame cottages o, Mrs. Ida Stevens; a, W. Klinkert; c, C. H. Ames signed, July 4; filed, July 14; cost $800.

SEATTLE, WASH.

The Hotel Denny is to be overhauled throughout the interior. Improvements will cost about $25,000.

REDLANDS

Architect J. W. Forsythe is drawing plans for a $3000 residence to be erected on Cajon street, near Fern by Dr. Jewett.

Architect O. H. Jones of Redlands is preparing plans for Carl Wells, for a two-story brick business building to be erected at that place. The same architect is also preparing plans for Mr. Borer, for a cottage residence.

Albert Johnson is preparing plans for two residences to be built on Jefferson street between Orchard and Vermont avenues.

BUILDING NEWS.

RIVERSIDE

S. L. Alderman is about to commence the erection of a residence in Hidalgo Place, to cost $1800.

Plans have been drawn for the rebuilding of the Methodist church. The new edifice will cost about $4000.

The lumber dealers report a brisk summer trade and the architects are in a good frame of mind.

LOS ANGELES

Architect A. L. Haley is preparing plans for Mrs A. Burgoine o a two-story eight-room residence to be built on West Twelfth street.

Architects Smith & Elder have prepared plans, for John Haddox of a two-story eight-room frame residence to be built at Bassett near el Monte.

Architect Frank D. Hudson has prepared plans for Frank Douglass of a two-story eight-room residence to be built on Burlington Ave.

Architect Fernadd Parmentier has prepared plans for Mr. H. Meyer, for a two-story eight-room residence to be erected corner of Eleventh and Union Ave. Estimated cost about $2000.

Architects Howard & Train have prepared plans for Dr. Pomeroy for extensive alterations to the residence corner of Washington and Toberman streets. The improvements will cost several thousand dollars

Architect O. P. Dennis has prepared plans for Fred S. Langdon for a cottage to be built on Pasadena avenue.

Architect August Wackerbarth has prepared plans for O. E. Roberts of a one and a half story frame residence to be erected at Hollywood.

Architects Eisen & Hune have prepared plans for F. J. Thomas; for a complete remodeling of his residence on Flower street.

Architect C. H. Brown has prepared plans for A. A. Hubbard for a two-story brick stable and carriage house with cement floors and shingle roof to be built on the corner of Ninth and Burlington ave.

Architects Morgan & Walls are preparing plans for John H. Jones, of a brick block on Spring and West Fifth street.

Plans are being prepared for Geo. D. Rowan, for an up-to-date brick building to be erected on west side of South Broadway.

Architects Eisen & Hune have prepared plans for the San Gabriel Power Company of a one story brick building to be used as an auxiliary power house to their present station on Los Angeles street near Third.

Preparations are being made for the erection of a building at the junction of East First and San Pedro streets. The property is owned by the Wilson estate but has been leased to parties who are making the necessary arrangements.

Weatherwax Screwless

DOOR KNOB.

Plans and Specifications Invited for an Hospital Building.

Public notice is hereby given to architects that competitive plans and specifications for the erection of an hospital building will be received by the Board of Supervisors on MONDAY AFTERNOON, September 12, 1898.

The proposed building to be of modern design and to be constructed of stone or brick, or of both, with all the latest scientific improvements.

The said hospital building to be erected on the lot of land commencing at the most southeasterly corner of a tract of land known as and designated, on the official map of the city and county of San Francisco, as the "Almshouse tract."

The said plans and specifications to be so prepared that the cost of the building shall not exceed in the aggregate the sum of three hundred thousand ($300,000) dollars.

The architect whose plans are adopted will be appointed architect and superintendent of the building, and will be required to give a good and satisfactory bond to insure the completion and construction of the said building for the amount of the cost as made by the said architect. The architects submitting plans determined by the Board to be second, third and fourth in merit will receive premiums of $1000, $750 and $500 respectively, with the understanding that any features of said plans and specifications which may be considered useful or necessary to be embodied in he plans adopted may be used without urther cost of charge.

JNO. A. RUSSELL, Clerk.

FACTS ABOUT PAINTS.

PHŒNIX

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

PURE

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

PAINT

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

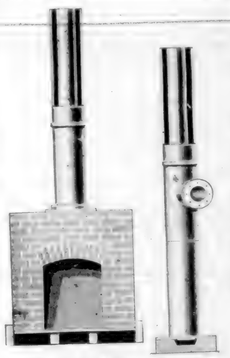
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

Send for illustrated circular.

For Sale by CHARLES J WATERHOUSE, 421 Market Street, San Erancisco.

To our Customers and Friends on the Pacific Coast.

Through frequent complaints made to us, we have learned that unprincipled and dishonest dealers on the Pacific Coast have counterfeited our trademark numbers and substituted inferior, spurious goods as ours, when ours were distinctly ordered, thus defrauding their customers and injuring our trade and reputation.

Our goods are acknowledged to be the best, and are fully warranted by us, and are marked with our name or initials or with our well-known trademark and catalogue numbers.

We request direct notice if any goods alleged to come from us, or bearing our trademark or numbers, prove to be other than the best, and perfect in every respect, as we will follow up and expose such frauds for our customers' and our own protection. We have no exclusive agents on the Coast, but our goods are obtainable from all respectable dealers in drawing materials, stationery, hardware, artists' material, etc.

Respectfully,

KEUFFEL & ESSER CO.,
New York.

BUILDING NEWS.

Bay near Leavenworth. To build; o, Neil O'Neil; a, A. W. Smith; c, C. M. MacGregor; signed, Aug. 8; filed, Aug. 11; cost $2170.

Broadway near Sansome: Alterations and additions, etc; o, Board of Education; a, T. J. Welsh; c, W. M. Fletcher; cost $2200.

California near Walnut. To build; o, E. O. Wilkins; a, Martens & Coffee; c, R. Trost; signed, Aug. 15; filed, Aug. 17; cost $2331.

Caselli Ave. near Falcon Ave. Cottage; o, P. Portwig; a, W. H. Armitage; c, D. Ross; signed and filed, Aug. 15; cost $1940.

Clayton near Waller. Three flats; a, C. A. Meussdorffer; c, A. H. Wilhelm; signed, Aug. 13; filed, Aug. 15; cost $4000.

Clayton near Hayes. All work except excavations, etc; o, Mrs. William McCormick; a, T. J. Welsh; c, Wm. Plant signed, July 30; filed, Aug. 1; cost $2232.

Eddy near Van Ness. Grading, brick work, etc; o, P. F. Butler; a, W. H. Lillie; c, John Furness; signed, Aug. 3; filed, Aug. 11; cost $15,288. Sewers, plumbing, etc; o, Ford Bros; signed, Aug. 3; filed, Aug. 11; cost $1880. Painting, etc; c, G. A. Petterson; signed, Aug. 3; filed, Aug. 11; cost $1435.

Ellis near Jones. Brick and terra cotta work; o, L. H. Sly; c, H. H. Larsen; signed, Aug. 15; filed, Aug. 16; cost $6285.

Fourteenth near Guerrero. Alterations and additions; o, Mary I. Keating; a, M. J. Welsh; c, T. F. Foley and H. A. Planz; signed, June 22; filed, July 26; cost $1498.

Fremont near Howard. Brick work, etc; o, Jane E. and C. M. Belshaw; c, J. W. Wissinger; sub-c, J. A. Wilson; cost $7975.

Franklin and Ellis. Excavating, etc; o, D. Jutton; a, C. A. Muessdorffer; c, R. Steglin; signed, Aug. 8; filed, Aug. 8; cost $1658. Carpentry work, etc; c, A. A. Olson; cost $1765. Plumbing, etc; c, G. C. Sweeny; cost $840. Painting, etc; c, J. F. Sullivan; cost $615.

Geary near Mason. Alterations and additions; o, Mrs. M. V. Baldwin; a, W. H. Lillie; c, M. J. Savage; signed, July 27; filed, July 30; cost $9200.

Golden Gate Ave. near Laguna. Excavation, etc; o, Judah Bons; a, M. J. Lyon; c, W. J. Field; signed, Aug. 2; filed, Aug. 13; cost $2094.

Golden Gate Ave. near Hyde. Alterations and additions; o, Mrs. Isabella Boyde; c, Anderson Bros; signed, July 13; filed, July 13; cost $1617.

Guerrero near 24th. Carpentry, brick work, etc; o, Dominican Sisters; a, Shea & Shea; c, Robert Trost; signed, Aug. 8; filed, Aug. 9; cost $2325.

Green near Fillmore. All work except plumbing, etc; o, Amelia M. Burnell; a, W. Mooser & Son; c, Petterson & Person; signed, July 27; filed, July 1; cost $3300.

Herzog Tract, lot 5, block 12. Two-story frame; o, William Strohbeck; c, August Schoor; signed, Aug. 12; filed, Aug. 15; cost $1535.

Hoffman Ave. near Elizabeth. To build; o, Jacob Heyman; c, Jacob Heyman; cost $2250.

Isabella near San Pablo Ave. Two-story frame; o, Lee E. Andrews; c, Robert McBeth; signed, Aug. 9; filed, Aug. 10; cost $1650.

Laguna near Washington. Cabinet work, etc; o, Dr. A. Barkan; a, Pissis & Moore; c, Fink & Schindler; signed, Aug. 8; filed, Aug. 15; cost $8376.

Linden Ave. near Gough. Two-tory tenement house; o, Arthur Kanzee; a, B. C. Clinch; c T. R. Bassett; signed, July 30; filed, Aug. 1; cost $1432.

BUILDING NEWS.

Lombard and Lyon. All work except painting; o, Agness Herman; a, E. A. Garin; c, Cameron & McDonald; signed, Aug. 4; filed, Aug. 4; cost $2888.

Lombard and Baker. To build; o, P. J. McGaffigan c, John Keneally; signed, July 27; filed, July 28; cost $1097.

Market and Hayes. Alterations and additions; o, Barflett and C. F. Doe, administrators; c, Robinson & Gillespie; sub-c, L. J. Campomenosi; signed, June 12; filed, July 21; cost $1860.

Market and Spear. Work for elevators; o, W. W. Young; a, Kenitzer & Barth; c, S. F. Novelty Works; signed, Aug. 10; filed, Aug. 12; cost $1650. Electric elevator; c, Fraser Electric Works; signed, Aug. 10; filed, Aug. 12; cost $4200.

Mission and 14th. Carpentry; iron work, etc; o, Southern Pacific Co; a, H. A. Schulze; c, Z. O. Field; signed, July 20; filed, July 28; cost $13,780. Excavation, etc; c, Quimby & Harrelson; cost $6495. Brick work, etc; c, O'Sullivan & O'Connor; cost $7566. Cast and wrought iron, etc; c, H. Ralston; cost $9198. Plastering, etc; c, Jesse E. Steere; cost $3172. Plumbing, etc; c, W. F. Wilson; cost $8003. Tinning, etc; c, S. F. Cornice Co; cost $1640.

Natoma and Russ. All work except plumbing, etc; o, Teresa Murphy; a, M. J. Welsh; c, Allen McDonald; signed, Aug. 4; filed, Aug. 4; cost $1400.

Pacific Ave. near Webster. Excavation and brick work; o, Jonas Schoenfeld; a, Salfield & Kohlberg; c, Miller & Beck; cost $1200.

Plymouth Ave. and Broad st. To build; o, Herman Kiepen; c, Earl F. Crane; signed, Aug. 15; filed, Aug. 15; cost $1925.

Post near Laguna All work except plumbing, etc; o, Leopold Auerbach; a, J. E. Wolfe; cost $425.

Powell and Vandewater. Two-story frame; o, W. M. Nichols; a, M. J. Welsh; c, K. C Gardner; signed, Aug. 10; filed, Aug. 12; cost $4425.

Second and Mission. Illuminating tiles and iron work for six-story brick; o, Wells, Fargo & Co; c, P. H. Jackson & Co; signed, July 29; filed, Aug. 2; cost $2867.

Silver near Third. To build; o, Mrs. Emilie Ursin; a, C. M. Rousseau; c, W. R. Kenny; signed, July 22; filed, July 26; cost $3135.

Stanyan and Beulah. Three-story frame; o, Antonio Versalovich; c, R. J. Pavert; signed, Aug. 13; filed, Aug 15; cost $4575.

Sixth near Shipley. Alterations and additions; o, Gustave Harshall; a, Shea & Shea; signed, July 30; filed, Aug. 4; cost $4374.50.

Seventh near Howard. All work except plumbing; o, Adolph Cohn; a, F. Schwerdt; c, Bernard Dryer; signed, Aug. 15; filed, Aug. 16; cost $2700.

Texas near 19th. To build; o, James Gallagher; sup. James Glacken; c, John Keneally; signed, Aug. 9; filed, Aug. 12; cost $1147.

Twenty-first and Chattanooga. To build; o, Patrick Ramaur; c, William Helbing; signed, July 26; filed July 22; cost $2500.

Twenty-fourth near San Bruno Ave. To build; a, T. J. Welsh; c, Donovan & Son; signed, Aug. 10; filed, Aug. 12; cost $2775.

Van Ness Ave. and Clay. To build; o, St. Luke's Church; a, Albert Sutton; c, Walker Brother Co; signed, Aug. 13; filed, 15; cost $32,500.

Washington near Spruce. Excavating, etc; o, H. Huddleston; a, Percy & Hamilton; c, Richardson & Gale; signed, Aug. 4; filed, Aug. 6; cost $7580. Carpentry, etc; c, Chris Chrisholm; cost $13,900. Plumbing etc; c, W. F. Wilson; cost $1759.

BUILDING NEWS.

Webster near Filbert. To build; o, Mrs. Agnes M. Goedje; c, W. F. Lloyd; cost $2050.

OAKLAND

Eight and Madison. To build; o, Mary Elfen; a, Alexander Thomson; c, A. Thomson & Co; cost $4414.

Fourteenth and Kirkham. Cottage; o, Ed. Swain; a, A. W. Smith; c, D. McLeod; cost $1240.

Thirteenth near Washington. To build; o, Abramson Bros; a, Chas. Mau; c, J. C. Caldwell; cost $3895.

Fourty-first and Adeline. To build; o, L. D. Fell; a, W. A. Graves; c, Geo. C. Nall; cost $1695.

Grove and 41st street. Brick work, etc. for Sth hool; o, Roman Catholic Archbishop of San Francisco; a, E. A. Garin; c, Cameron & McDonald; cost $7949.

EAST OAKLAND

Fifteenth near 18th. To build; o, D. C. Talbot; a, D F. Oliver; c, Jacob House cost $1280.

CLAREMONT

Architect C. H. Brown is preparing plans for the Pearson Hall of Science, a new building to be erected at Claremont, Cal., at a cost of $25,000. It is an imposing design of two stories high and basement, 60x90 feet, built of brick, faced with cream colored pressed brick and terra-cotta.

MILL VALLEY

Mount Tamalpais. One and one-half story frame; o, Mill Valley and Mount Tamalpais Scenic Railway; a, Percy & Hamilton; c, B. F. Ellis; cost $1765.

BERKELEY

L t 6, block 8, Antisell's Map of Villa Lots. To build; o, P. P. Robertson; a, Cunningham Bros; c, J. C. Caldwell; cost $2308.

BAKERSFIELD

W. H. Scribner has let the contract for a three-story brick building designed for a theatre to be build on Chester avenue.

REDLANDS

Architect J. W. Forsythe has prepared plans for J. H. Fisher for a three-story brick to be on he corner of Orange street; total cost about $14,000.

DUTCH FLAT

A public school building at Dutch Flat will be built soon; bids close on September 3d; P. F. Martin, architect, cost $4500.

LOS ANGELES

A. S. Rendall will creet this fall a brick building on the lot at the corner of Los Angeles and Boyd Sts.

Architect G. F. Costerisan is preparing plans for the trustees of San Fernando school district for an addition of two rooms to their school building. Plans will be ready for bids about Aug. 1st.

Architects Eisen & Hunt have been instructed by the board of supervisors to prepare plans for a one-story brick building to be used as an insane ward on the county hospital grounds on Mission road and the probable cost will be about $2500.

Architects Locke and Munsell have prepared plans for Hugh Phipps of a two-story frame residence to be built on Maryland streets.

Architect Chas. L. Strange is preparing plans for a two story frame and stone residence to be built on W Adams street. He is also preparing plans for four two story residences to be erected at Riverside.

Architect John Parkinson has prepared plans and

The Yale & Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key, afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," the range of products and grades is such as to meet conditions where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

NOTICE is hereby given that Mr. Tom M. Grant is no longer connected with this Journal.—E. H. Burrell, Lessee and Publisher.

THE Editor of the *Architectural Record* endorses the scheme of the Classical Design and Detail Company, Limited, because of the "substantial benefits to architects" in an apology to his readers under the caption "Architecture Made Easy". It is unique in its way so we print it verbatim:

"It is not our practice to admit commercial reading into these pages of the magazine, but, in the case of the circular that follows we have deviated from our fixed policy because of the substantial benefits the "Classical Design and Detail Co." offers to the architectural profession and to the cause of classical art. We are sure nobody will deny that the present conditions of practice demand the formation of a concern like the one just incorporated, which certainly fills most satisfactorily "a long-felt want."

The prospectus of this C. D. and D. Co., is rather startling in many of its announcements which, of course, amounts to innovations as for instance the opening paragraph which boldly declares that "it is well-known that the chief drawback to the successfull practice of architecture in the United States is the enormous burden imposed upon the architect by his *office expenses*." Whereas we were always somewhat inclined to the opinion that a "lack of business" had con-

siderable to do with it, but, of course, with this highly, though apologetically endorsed prospectus before us, we must have time to think.

Further on we are told that this condition of affairs is entirely unnecessary, in the actual condition of architecture in this country, and that it is in view of these facts that the Classic Design and Detail Company has been formed.

Then again architects are gently informed that the present methods are really obsolete. Not content with these inspired efforts for innovations, we are given in the summing up a climax of ingenuity that will take high rank for its peculiar power wherever read. It is as follows: "The business of an architect, it is more and more clearly coming to be recognized, *is not to design buildings, but to get buildings to design*."

This is truly a master piece, and beyond a doubt the most majestic enterprise ever entrusted to the faculties of man—should have been the *Record's* endorsement of that paragraph.

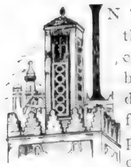
THE ACTION OF SEA-WATER UPON HYDRAULIC CEMENTS.

BY DR. WILHELM MICHAELIS — TRANSLATED AND ABSTRACTED BY WALTER FRANCIS REID.

From Proceedings of the Institute of Civil Engineers [England]

Vol. CXXIX.

CONTINUED FROM LAST NUMBER.



IN THE 1:3 briquettes only 13.3 per cent of the total lime, and in the 1:5 only 24.8 per cent was converted into carbonate. These briquettes being very small, and the conditions for the absorption of carbonic acid favorable, it is evident that even a long exposure of concrete blocks to the air would only cause a very thin film of carbonate to be formed. The whole of the lime was not converted into carbonate until the mortar had been coarsely powdered and exposed to the action of carbonic acid for some time. Immersed in sea-water, or in a 2 per cent solution of magnesium sulphate, the briquettes which had been protected from carbonic acid soon disintegrated, and even those which had been carbonated were strongly attacked in seven months, especially the 1:5 mortar, although this had absorbed more carbonic acid.

In fresh water the conditions are more favorable, for only the free lime can be dissolved or converted into carbonate. The more lime is dissolved out the more insoluble are the residual silicates and aluminates. The whole of the lime can never pass into solution, although this may be effected on a small scale when carbonic acid is excluded. A well mixed and burnt Portland cement may contain 70 per cent of lime and yet resist the action of fresh water.

The magnesia which is deposited during the action of sea-water upon hydraulic mortar is a preservative agent which tends to close the pores of the mass. It would be more correct to speak of the injurious action of the sulphates in sea-water than to attribute such action to the magnesia salts, although it is true that magnesium sulphate is the special salt which acts in sea-water. The sulphates of lime or of the alkalis, in fact, any soluble sulphate, have the same destructive action, but no not act with the same degree of energy.

The author finds as the result of his investigations that those cements which are richest in lime are those which offer the least resistance to sea-water. The addition of lime or of more calcareous cements to Portland cement mortar is therefore unsuitable, and modern Portland cements of high strength, but rich in lime, are less suitabe for marine work than the older cements containing less lime. A mortar containing free caustic lime is as unstable from a physical as from a chemical point of view. By the reaction already explained, great internal strains are produced and expansion and cracking continue, sometimes for many years. All these defects may be avoided by offering to the lime, which remains or becomes free during the hardening process, hydraulic silica or alumina with which it can form more stable compounds. The disadvantage of the efflorescence of caustic alkali cannot be avoided; but as the quantity is small, and it is easily soluble, this caustic alkali cannot endanger the stability of the mortar. In water the alkali is simply washed out; in the air it is only a temporary efflorescence which cannot be washed off.

The addition of milk of lime to Portland cement mortars must be injurious and hastens their destruction. Even in fresh water the advantages of such an addition are only apparent; the excess of lime is easily washed out and the mortar soon becomes porous. Even in two to three years a diminution in the strength of such cement-lime mortars takes place. The action of carbonic acid may come to the rescue, but the chief use of this addition is to make poor mortars more plastic.

In carrying out experiments on the action of sea-water upon cements, it is of importance that the test-pieces should be as porous as possible, otherwise the results would only be delayed. In carrying out a series of experiments with various mortars the author used artificial sea-water, and solutions of calcium sulphate, magnesium sulphate and sodium sulphate. The mortars were moulded in the form of prisms ten centimeters long with a rectangular section of five cubic centimeters. For twenty-four hours the briquettes were allowed to harden in moist air, from which carbonic acid was excluded; they were then placed in the test solutions. The solutions were renewed daily for fourteen days, weekly for three months, and then monthly. One of the mixtures which withstood the action of calcium sulphate best was Teil lime mixed with five parts of standard sand; but all mixtures containing hynraulic silica as hydrate, or in the form of trass or burnt kaolin, were but slightly acted upon, and remained intact after the lapse of two years.

In a one per cent magnesium sulphate solution similar results were obtained. Neat Portland-cement mixtures, without the addition of hydraulic substances, soon disintegrated, especially in the case of those cements rich in alumina. A Bavarian Roman cement containing 47.2 per cent of lime stood well, while a Bosnian Roman cement with 49 per cent of that substance began to show signs of deterioration. Long before there are visible signs of disintegration through the action of sea-water the tensile strength indicates whether an injurious action is taking place. As porous briquettes are more rapidly acted upon than impervious ones, it is advisable to use a mortar containing one part of cement to five parts of sand, rather than one composed of the 1:3 mixture. A number of experiments were carried out by the author, in which the briquettes were composed of one part of cement mixed with five parts by weight of Berlin standard stand.

ON THE SALINE EFFLORESCENCE OF BRICKS.

THE CAUSES LEADING TO IT, AND THE PRACTICAL MEANS OF AVOIDING THE SAME.

BY OSCAR GERLACH (PH. D., BERLIN.)

I PROPOSE in the following article, the first in a brief series, to consider the mode of origin of the common saline efflorescence of bricks. A series of researches which I conducted at the *Laboratory for Clay Industries* of Professor Seeger and E. Cramer, of Berlin, Germany, and which were continued in practical work in America, furnished me with results that not only afford a clear explanation of the origin of efflorescence, but also point to the practical means of avoiding the same. The means of avoidance I shall discuss in a separate article.

By "efflorescence" I understand what is commonly termed "whitewash," wherever and whenever such incrustations appear. For the sake of clearness I shall follow the process of brickmaking in all its successive single stages, as commonly conducted, and point out at each step the causes concerned in the production of the chemical salts occasioning the annoying superficial colorations in question.

Most noticeable and most annoying are the *white* efflorescences on red or yellow brick; less striking are the green and yellow incrustations on light brick. The white efflorescences are always of inorganic or mineral origin, being mainly sulphates of lime, magnesia, and alkalies. We shall consider here the formation of the white efflorescences reserving the green and yellow for another occasion, and as a matter of clearness distinguish carefully between:—

1. The formation of efflorescent sulphates which are found *already formed* in the clay pits, or which are first formed from *allowing the clay to lie unused* for a certain length of time, or which arise at any time *during the making of the clay* into green bricks; and

2. The formation of sulphates which arise during the water smoking and during the burning of the green material in the kilns

This distinction is necessary, because practical brickmakers are prone to think that water-smoking alone is the cause of the whitewashing sulphates making their appearance on the finished products.

I.

ON THE FORMATION OF THE EFFLORESCENT SULPHATES IN THE CLAY BEDS, ETC.

The majority of clays used in brick and terra-cotta making contain greater or less quantities of mineral salts. Chemical analysis has shown that these salts are sulphates of lime and magnesia, less frequently of iron and alkalies. These sulphates are formed by the weathering of finely and uniformly distributed particles of iron pyrites, which is an almost constant accompaniment of the clay. Through the action of water, air, and heat the iron pyrites (FeS^2) is gradually oxidized and converted into ferrous sulphate ($FeSO^4$), which, being easily soluble in water, is, in union with the carbonates of lime, magnesia, and alkalies, whose constant presence can also be shown, converted into the respective sulphates of these combinations. For example, $FeO.SO_3 + CaO.\ CO_2 = FeO.\ CO_2 + CaO.\ SO_3$.

It is readily intelligible now that the more minute the distribution of the iron pyrites is in the clay, and the more the mass as a whole is exposed to the influences of the weather, *i. e.*, to the effects of water, air, and heat, the greater the quantities of iron pyrites oxidized and the greater the quantities of soluble sulphates stored up in the clays. If we are using, for instance, a stony clay belonging to the carboniferous formations, which always contain heavy quantities of iron pyrites (*e. g.*, blue shale), and work the same into green bricks immediately, and at the beds where the clay is found, then certainly the whitewashing is far less apt to be noticeable than if the clay had been suffered to lie for months before using, exposed and in the open air.

To prove this, I analyzed several specimens of clay from the same pit, and so determined the amount of soluble sulphates in each. One specimen was taken from the upper layer of the clay, another from a lower layer quite protected from the air and heat. The analysis showed that the upper layer contained four times as much soluble sulphates as the lower, protected layer.

Another experiment yielded similar results. I took *three* specimens from the *same* layer of clay. Of the first specimen, 100 grams were *immediately* analyzed and the amount of sulphates therein contained determined; of the second specimen, 100 grams were finely pulverized, moistened, and exposed to the weather for three months, and at the expiration of that time analyzed for the amount of sulphates; while 100 grams of the third specimen were likewise finely pulverized and let lie for three months in a dry, hermetically sealed tin box and then analyzed. It turned out that specimens 1 and 3 contained almost equal amounts of sulphates, while specimen 2 showed six times the amount of the others. Another clay, likewise belonging to the carboniferous period, having been let lie for months in the open air, left behind it on the ground where it had been heaped large quantities of beautifully formed gypsum crystals.

But even if such clays are worked into bricks immediately upon being transported from the pits, it does not necessarily follow that the formation of sulphates will be entirely prevented. If the green bricks be let stand a long while in the drying rooms a constant oxidation of the iron pyrites will take place on the surface of the bricks through the action of the moist atmosphere, and, concomitantly with this, the formation of sulphates which, while not visible to the eye in the green bricks, will, after burning, make their appearance in the shape of whitewash. To prevent this, not only is the immediate working of the clay into green bricks necessary, but it is also requisite to dry and to burn the bricks with all the expedition possible.

The oxidation of iron pyrites is accordingly a main cause of the formation of sulphates occasioning whitewash. A second source is the sulphur contained in the water employed in the preparation of the clay. This water frequently con-

siderable to do with it, but, of course, with this highly, though apologetically endorsed prospectus before us, we must have time to think.

Further on we are told that this condition of affairs is entirely unnecessary, in the actual condition of architecture in this country, and that it is in view of these facts that the Classic Design and Detail Company has been formed.

Then again architects are gently informed that the present methods are really obsolete. Not content with these inspired efforts for innovations, we are given in the summing up a climax of ingenuity that will take high rank for its peculiar power wherever read. It is as follows: "The business of an architect, it is more and more clearly coming to be recognized, *is not to design buildings, but to get buildings to design.*"

This is truly a master piece, and beyond a doubt the most majestic enterprise ever entrusted to the faculties of man—should have been the *Record's* endorsement of that paragraph.

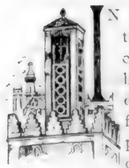
THE ACTION OF SEA-WATER UPON HYDRAULIC CEMENTS.

BY DR. WILHELM MICHAELIS — TRANSLATED AND ABSTRACTED BY WALTER FRANCIS REID.

From Proceedings of the Institute of Civil Engineers [England]

Vol. CXXIV.

CONTINUED FROM LAST NUMBER.



IN THE 1:3 briquettes only 13.3 per cent of the total lime, and in the 1:5 only 24.8 per cent was converted into carbonate. These briquettes being very small, and the conditions for the absorption of carbonic acid favorable, it is evident that even a long exposure of concrete blocks to the air would only cause a very thin film of carbonate to be formed. The whole of the lime was not converted into carbonate until the mortar had been coarsely powdered and exposed to the action of carbonic acid for some time. Immersed in sea-water, or in a 2 per cent solution of magnesium sulphate, the briquettes which had been protected from carbonic acid soon disintegrated, and even those which had been carbonated were strongly attacked in seven months, especially the 1:5 mortar, although this had absorbed more carbonic acid.

In fresh water the conditions are more favorable, for only the free lime can be dissolved or converted into carbonate. The more lime is dissolved out the more insoluble are the residual silicates and aluminates. The whole of the lime can never pass into solution, although this may be effected on a small scale when carbonic acid is excluded. A well mixed and burnt Portland cement may contain 70 per cent of lime and yet resist the action of fresh water.

The magnesia which is deposited during the action of sea-water upon hydraulic mortar is a preservative agent which tends to close the pores of the mass. It would be more correct to speak of the injurious action of the sulphates in sea-water than to attribute such action to the magnesia salts, although it is true that magnesium sulphate is the special salt which acts in sea-water. The sulphates of lime or of the alkalis, in fact, any soluble sulphate, have the same destructive action, but no not act with the same degree of energy.

The author finds as the result of his investigations that those cements which are richest in lime are those which offer the least resistance to sea-water. The addition of lime or of more calcareous cements to Portland cement mortar is therefore unsuitable, and modern Portland cements of high strength, but rich in lime, are less suitabe for marine work than the older cements containing less lime. A mortar containing free caustic lime is as unstable from a physical as from a chemical point of view. By the reaction already explained, great internal strains are produced and expansion and cracking continue, sometimes for many years. All these defects may be avoided by offering to the lime, which remains or becomes free during the hardening process, hydraulic silica or alumina with which it can form more stable compounds. The disadvantage of the efflorescence of caustic alkali cannot be avoided; but as the quantity is small, and it is easily soluble, this caustic alkali cannot endanger the stability of the mortar. In water the alkali is simply washed out; in the air it is only a temporary efflorescence which cannot be washed off.

The addition of milk of lime to Portland cement mortars must be injurious and hastens their destruction. Even in fresh water the advantages of such an addition are only apparent; the excess of lime is easily washed out and the mortar soon becomes porous. Even in two to three years a diminution in the strength of such cement-lime mortars takes place. The action of carbonic acid may come to the rescue, but the chief use of this addition is to make poor mortars more plastic.

In carrying out experiments on the action of sea-water upon cements, it is of importance that the test-pieces should be as porous as possible, otherwise the results would only be delayed. In carrying out a series of experiments with various mortars the author used artificial sea-water, and solutions of calcium sulphate, magnesium sulphate and sodium sulphate. The mortars were moulded in the form of prisms ten centimeters long with a rectangular section of five cubic centimeters. For twenty-four hours the briquettes were allowed to harden in moist air, from which carbonic acid was excluded; they were then placed in the test solutions. The solutions were renewed daily for fourteen days, weekly for three months, and then monthly. One of the mixtures which withstood the action of calcium sulphate best was Teil lime mixed with five parts of standard sand; but all mixtures containing hynraulic silica as hydrate, or in the form of trass or burnt kaolin, were but slightly acted upon, and remained intact after the lapse of two years.

In a one per cent magnesium sulphate solution similar results were obtained. Neat Portland-cement mixtures, without the addition of hydraulic substances, soon disintegrated, especially in the case of those cements rich in alumina. A Bavarian Roman cement containing 47.2 per cent of lime stood well, while a Bosnian Roman cement with 49 per cent of that substance began to show signs of deterioration. Long before there are visible signs of disintegration through the action of sea-water the tensile strength indicates whether an injurious action is taking place. As porous briquettes are more rapidly acted upon than impervious ones, it is advisable to use a mortar containing one part of cement to five parts of sand, rather than one composed of the 1:3 mixture. A number of experiments were carried out by the author, in which the briquettes were composed of one part of cement mixed with five parts by weight of Berlin standard stand.

ON THE SALINE EFFLORESCENCE OF BRICKS.

THE CAUSES LEADING TO IT, AND THE PRACTICAL MEANS OF AVOIDING THE SAME.

BY OSCAR GERLACH (PH. D., BERLIN.)

I PROPOSE in the following article, the first in a brief series, to consider the mode of origin of the common saline efflorescence of bricks. A series of researches which I conducted at the *Laboratory for Clay Industries* of Professor Seeger and E. Cramer, of Berlin, Germany, and which were continued in practical work in America, furnished me with results that not only afford a clear explanation of the origin of efflorescence, but also point to the practical means of avoiding the same. The means of avoidance I shall discuss in a separate article.

By "efflorescence" I understand what is commonly termed "whitewash," wherever and whenever such incrustations appear. For the sake of clearness I shall follow the process of brickmaking in all its successive single stages, as commonly conducted, and point out at each step the causes concerned in the production of the chemical salts occasioning the annoying superficial colorations in question.

Most noticeable and most annoying are the *white* efflorescences on red or yellow brick; less striking are the green and yellow incrustations on light brick. The white efflorescences are always of inorganic or mineral origin, being mainly sulphates of lime, magnesia, and alkalies. We shall consider here the formation of the white efflorescences reserving the green and yellow for another occasion, and as a matter of clearness distinguish carefully between:—

1. The formation of efflorescent sulphates which are found *already formed* in the clay pits, or which are first formed from *allowing the clay to lie unused* for a certain length of time, or which arise at any time *during the making of the clay* into green bricks; and

2. The formation of sulphates which arise during the water smoking and during the burning of the green material in the kilns

This distinction is necessary, because practical brickmakers are prone to think that water-smoking alone is the cause of the whitewashing sulphates making their appearance on the finished products.

I.

ON THE FORMATION OF THE EFFLORESCENT SULPHATES IN THE CLAY BEDS, ETC.

The majority of clays used in brick and terra-cotta making contain greater or less quantities of mineral salts. Chemical analysis has shown that these salts are sulphates of lime and magnesia, less frequently of iron and alkalies. These sulphates are formed by the weathering of finely and uniformly distributed particles of iron pyrites, which is an almost constant accompaniment of the clay. Through the action of water, air, and heat the iron pyrites (FeS^2) is gradually oxidized and converted into ferrous sulphate ($FeSO^4$), which, being easily soluble in water, is, in union with the carbonates of lime, magnesia, and alkalies, whose constant presence can also be shown, converted into the respective sulphates of these combinations. For example, $FeO.SO_3 + CaO.\ CO_2 = FeO.\ CO_2 + CaO.\ SO_3$.

It is readily intelligible now that the more minute the distribution of the iron pyrites is in the clay, and the more the mass as a whole is exposed to the influences of the weather, *i. e.*, to the effects of water, air, and heat, the greater the quantities of iron pyrites oxidized and the greater the quantities of soluble sulphates stored up in the clays. If we are using, for instance, a stony clay belonging to the carboniferous formations, which always contain heavy quantities of iron pyrites (*e. g.*, blue shale), and work the same into green bricks immediately, and at the beds where the clay is found, then certainly the whitewashing is far less apt to be noticeable than if the clay had been suffered to lie for months before using, exposed and in the open air.

To prove this, I analyzed several specimens of clay from the same pit, and so determined the amount of soluble sulphates in each. One specimen was taken from the upper layer of the clay, another from a lower layer quite protected from the air and heat. The analysis showed that the upper layer contained four times as much soluble sulphates as the lower, protected layer.

Another experiment yielded similar results. I took *three* specimens from the *same* layer of clay. Of the first specimen, 100 grams were *immediately* analyzed and the amount of sulphates therein contained determined; of the second specimen, 100 grams were finely pulverized, moistened, and exposed to the weather for three months, and at the expiration of that time analyzed for the amount of sulphates; while 100 grams of the third specimen were likewise finely pulverized and let lie for three months in a dry, hermetically sealed tin box and then analyzed. It turned out that specimens 1 and 3 contained almost equal amounts of sulphates, while specimen 2 showed six times the amount of the others. Another clay, likewise belonging to the carboniferous period, having been let lie for months in the open air, left behind it on the ground where it had been heaped large quantities of beautifully formed gypsum crystals.

But even if such clays are worked into bricks immediately upon being transported from the pits, it does not necessarily follow that the formation of sulphates will be entirely prevented. If the green bricks be let stand a long while in the drying rooms a constant oxidation of the iron pyrites will take place on the surface of the bricks through the action of the moist atmosphere, and, concomitantly with this, the formation of sulphates which, while not visible to the eye in the green bricks, will, after burning, make their appearance in the shape of whitewash. To prevent this, not only is the immediate working of the clay into green bricks necessary, but it is also requisite to dry and to burn the bricks with all the expedition possible.

The oxidation of iron pyrites is accordingly a main cause of the formation of sulphates occasioning whitewash. A second source is the sulphur contained in the water employed in the preparation of the clay. This water frequently con-

tains gypsum; and since many clays require so much as 30 per cent of water for rendering them plastic, the gypsum present in the water naturally contributes a high quota to the formation of the annoying superficial efflorescences in question. So, too, by various other admixtures, as mineral colorings, oxide of iron, ochre, superoxide of manganese, the whitish efflorescences can be argumented. Wherefore, it is necessary that all such substances when used as admixtures should, without exception, be analyzed for the amount of sulphates they contain.

The quantity of water requisite for working the clay depends wholly on the nature of the clay and on the peculiar methods employed in working it. The greater the quantity of water, the greater the quantity of the sulphates dissolved in it, and the greater the quantity of dissolved salts deposited on the surface of the bricks in drying.

The method of drying is also of paramount importance, both as bearing on the formation of these effloresences and as affecting their visibility on the surface. The quicker the drying can be perfected, the more advantageous will be the appearance of the burnt product, for in a perfectly dry brick all further oxidation of the iron pyrites is absolutely excluded; and then again, in consequence of the rapid evaporation of the water, the dissolved sulphates are not wholly deposited on the surface of the product, but in large part are left behind in the pores of the clay. The drying process consequently deserves the highest attention at the hands of the practical brickmaker. But since the space at my present disposal is limited, I shall reserve the discussion of the advantages and disadvantages of the different methods of drying for a future occasion.

To recapitulate: the substances giving rise to the efflorescence or whitewash of green clay products are (1) the soluble sulphates contained in the natural clays, and (2) the sulphates formed during the storing and initial treatment of the clays consequent upon the weathering of the iron pyrites and its resultant transformation into sulphuric bases. It remains to be mentioned that the efflorescences which find noticable lodgment upon the green, unbaked material are subsequently burnt in indelibly on the surface of the brick, and can be removed neither by chemical nor mechanical means.

ON THE FORMATION OF SULPHATES WHICH ARISE DURING THE WATER-SMOKING AND DURING THE BURNING OF THE GREEN MATERIAL IN THE KILNS.

The presence of iron pyrites in the clay is, we have seen, the main cause of the origin of whitewashing sulphates on the surface of the unburnt material, and iron pyrites again is chiefly concerned in the production of whitewashing sulphates during the water-smoking and burning of the green products. This happens in a twofold manner—first, and again, by the presence of iron pyrites in the clay; and secondly, and particularly, by the iron pyrites contained in the coal, which is mostly used as a fuel.

In burning two processes are distinguished: (1) water-smoking, and (2) burning proper.

WATER-SMOKING.

The object of the water-smoking is to expel the water which has been mechanically absorbed by the clay, and which still remains in after drying—the so-called "hygroscopic' water,—whereby the clay is throughly dryed, but losses none of its original physical qualities. The purpose of burning, on the other hand, is (1) the expulsion of the water *chemically* contained in the clay (clay substance being essentially $Al_2O_3(SiO_2)+2H^2O$, (2) the chemical disintegration of the several components of the clay, and (3) a more or less perfect fusion of the individual argillaceous particles, whereby a definitive and permanent alteration of the substance is attained. With the loss of the chemically contained water, the clay losses its plasticity—a property so essential to the manufacture of argillaceous products.

We shall consider the process of water-smoking first, which has for its object the expulsion of the hygroscopic water. Since water is converted into steam at 212 degs. Fahr., this latter is the proper temperature for the process—attainable only by the artificial convection of heat to the products, *i. e.*, by the consumption of fuel. But since the size and the construction of the kiln in which the water-smoking is conducted renders it absolutely impossible for a perfectly uniform temperature to be obtained throughout the whole enclosed space, consequently that portion of the kiln and of the contents of the kiln which first comes in contact with the hot gases from the fireplace will be heated first. At these points a part of the water in the green products will be converted into steam, whilst at points more remote from the fireplace scarcely any rise at all in temperature will be noticeable. At these latter points the water vapor origjnating at the first points will be condensed and precipitated on the surface of the cold green products, whence, since the clay is strongly hygroscopic, it will be absorbed into the interior of the bricks. If the clay, now, still contains soluble sulphates in its interior, these sulphates will be dissolved in the water, and later, when the points in question have in their turn reached evaporating heat, will be drawn to the surface of the bricks, and, as the heat is increased, be burnt in there. If the green clay does not contain sulphates, or if the sulphates be rendered innocuous by the admixture of appropriate chemicals, the water so condensed will have no injurious effect upon the appearance of the bricks, provided the fuel employed contains no sulphur. But if a sulphurous fuel be employed,—for example, coal, which always contains more or less iron pyrites,—the water will absorb the gases of the sulphurous acids producted by the combustion of the iron pyrites, and this diluted acidic solution will act on the carbonates in the clay and form sulphurous salts, which, as the heat increases, will come to the surface and there be oxidized to sulphuric salts, thus causing again the annoying colorations.

To be continued.

THE USE OF SHEET IRON AND STEEL.

THE USE of sheet iron and steel in the construction of buildings has increased enormously of late. Not only are ornamental cornices a feature of some very handsome buildings, but in many instances the entire front of the building is covered with sheet steel in imitation of the pressed brick or rock, which when painted and sanded gives a very handsome effect. Corrugated iron for roofing and siding is used for manufacturing buildings, storage buildings, and of late years has been largely employed for sheds on the docks of various seaport cities. One of the largest buildings that has been covered with sheet iron is that of the Western Oil Manufacturing Company, at Belleville, N. J. The main building is 30x100 feet and 100 feet high. The extension at the right is 30x60 feet and 35 feet high, and the left extension is 100 feet long, a portion of which is 40 feet wide, and the remainder 20 feet wide, and the whole extension is 35 feet in hight. Sheet iron was selected as a covering for this building, owing to the protection afforded against contiguous fires and for its cheapness as compared with clapboarding. Clapboarding of a good quality put on the building was found to be worth between 5 and 6 cents per square foot, and the sheet iron covering of No. 24 black iron, 30x96 inches in size, put on, cost a little more than half the cost of clapboarding, owing to the little labor required, and the large space covered with a sheet of iron. The buildings are of frame construction, and the timbers are covered with a sheeting of 1-inch board. The sheets are attached to these boards with a layer of building paper bedepth, and several tons were required for the covering. After the work was completed the entire building was treated with one coat of red lead paint. The wooden tanks holding the water supply for the buildings, which were not set upright at the time the picture was taken, are also covered with sheet iron. Galvanized iron was used in covering the tanks, and galvanized iron was also used in covering the building which supports the water tanks. This building is 20x40 feet and 100 feet high—*The Improved Bulletin.*

TESTS OF CAST-IRON COLUMNS.

A VERY important series of tests of cast-iron columns has recently been completed at Phœnixville, Pa., by the department of buildings of New York city, and from an extensive account given in *Engineering News* we make some abstracts.

Three sets of columns were tested to destruction in the hydraulic testing machine of the Phœnix Bridge Company, these being respectively 15 feet 10¼ inches long by 15 inches in diameter; 13 feet 4 inches long by 8 inches in diameter; and 10 feet long by 6 inches in diameter; the thickness varying from 1 11-16 inches to ⅝ of an inch. In the first group were two columns taken from the "Ireland Building," which collapsed in the summer of 1895, in New York, and four similar ones cast for the purpose of the test, while the second and third groups each consisted of two columns of kinds used in regular building construction, made by well-known firms, and were fair samples, coming within the provisions of the law.

The data of the tests are tabulated in the paper referred to, and some of the salient features may be especially noted. With but few exceptions the thickness varied materially in different portions of the same column, so that in one instance the metal on one side was 1¼ inches thick, and on the other only ⅝ of an inch; and, although this was an extreme case, there was a decided irregularity of thickness, which probably affected the strength materially. All of the 15-inch columns were broken, except one, which was nearly uniform in thickness, and which remained intact at the maximum pressure of the testing machine—a load of more than 2,082,000 pounds, or more than 40,000 pounds per square inch of area. The breaking load of the others of this group varied from 25,000 to 30,000 pounds per square inch, the variations being apparently due to the presence of cinder, foundry dirt, chaplets, and blow-holes. The smaller columns were all broken with loads ranging from 22,000 to 32,000 pounds per square inch of area.

According to the building law of the city of New York, the strength of all columns and posts is to be computed by Gorden's formula, using a coefficient of 80,000, and a factor of safety of five for cast iron. The application of Gordon's formula, under these conditions, to the columns tested shows that the 15-inch columns should have a breaking strength of 75,000 pounds per square inch, instead of which it actually ranged from 25,000 to 40,000 pounds; while for the 6-and 8-inch columns the breaking strength by the formula should be 40,000 pounds per square inch, instead of 32,000 to 22,000 pounds, as shown by the tests.

Had these columns, therefore, been loaded as heavily as the law permits, the factor of safety in some cases would have been only a little more than 2, instead of 5 as intended. Judging from the physical description given of the columns tested, this discrepancy is much more likely to be due to the defects in the castings than to the inaccuracy of the formula, and apparently a requirement for better material and more-carefully-made castings would raise the strength nearly, if not quite, to that indicated by computation.

An interesting feature of the paper is the description of the calibration of the Phœnixville testing machine by comparison with the Emery testing machine in the United States Arsenal at Watertown, Mass. This calibration was effected by testing a special soft-steel Phœnix column, first at Watertown and then at Phœnixville, using a roller extensimeter reading to 0.0001 inch, the conditions being reproduced as nearly as possible in the second test, and the same extensimeter being used. The result showed the gage readings of the Phœnix machine to be from 15 to 17 per cent higher than the actual values, this being due to fraction of the machine and possibly to gage error. By using this correction, the tests at Phœnixvilte are made comparable with those at Watertown, with a possible error of about 3 per cent.

LESSON FROM FIRE AND PANIC.

WHEN I undertook this subject the fatal fire at the Paris Charity Bazaar had not happened, nor did we anticipate that great disaster among the warehouses at Cripplegate, which has added its own unnecessary lesson. Indeed, neither of these events was necessary, for they conveyed no warning not already known, and they were useless, for by this time they are practically disregarded.

The fact that the destruction of a building by fire is an improbability removes from it the class of considerations with which the architect usually deals. In proportion to the number of buildings fires are exceedingly few, considering the variety of risks I might say surprisingly few; and if it is a hundred thousand to one against a fire in a particular place on a given day, the ordinary man, environed by more threatening perils, will scoff at precaution and take his chance. But after calamity the general public with all its tongues asks who the precaution was not taken, and looks out for a victim. By the standard then set up, and not by

any doctrine of chances, the architect may expect to be judged.

It is a question whether danger from fire is not increasing in spite of Building Acts. Our buildings are getting more lofty, more closely packed together, and more thickly inhabited. In commercial buildings the rooms are larger and more encumbered with goods, among and over which manufacturing processes are carried on. There is more machinery actuated by heat. The timber we use is more easily combustible, fittings are lighter, and everything is kept warmer and drier. All our arrangements for obtaining light, from the lucifer match to gas and mineral oil and electricity, are novel and productive of new dangers. The proportion of window openings to wall space is much increased, and with the growth of honesty outside, or trustfulness within, shutters have been abandoned. The old-fashioned solid window frame that stood flush with the face of the wall, and being dangerous had to be abandoned, is through modern fashion being brought out again from its reveal and made in thin casing which will catch fire and fall into the street. Lifts going through several stories neutralize the advantage of fire-resisting floors. lighting areas common to different premises do away with the security of the party-wall. Unrestricted skylights bring ridicule on the incombustible roof covering of the Building Acts. In fact the most scrupulously legal building of brick or stone and slate may be no more than a kind of grate in which its internal structure and its contents can be most conveniently burned. So in the Cripplegate fire, the progress was about as rapid, and the destruction over its limited area no less complete, than in the Great Fire of 1666; and if our arrangements for the extinction of fire had not made immense progress, this recent event might have rivalled that great calamity.

Our own lesson from this must be to improve by all means the construction and arrangement of buildings, even though we may be in advance of Building Acts. We cannot widen the streets, nor increase the unoccupied areas, nor reduce the necessary openings for light, nor dictate to the trader modes of conducting his business which would make his business impossible, nor can we do much in advance of public opinion to diminish the numbers of an audience or spread them over a larger area. The most that we can do is to diminish the chances of fire and to delay its progress, to prevent its passage from room to room and from house to house, to so arrange the construction that a fire may be more easily put out, and as regards the safety of the inmates, to provide the best means of escape.

We should be wiser if we knew more of the causes of fires. The final comment on most of our great fires is "cause unknown." They have destroyed the evidence of their origin. We learn something from the records of those that are most easily extinguished, and we should learn more from the far greater number that are discovered and dealt with on the first alarm without troubling the fire brigade. In one of those summer exhibitions that are spread over buildings of a temporary character, I had information of ten such alarms within six months. In my own house we have had, through no fault of ours, at least three of the narrowest escapes from the kind of gas explosion by which the house of one of my friends was lately wrecked. We may learn something from these and other failures, but our great lesson must be to distrust the safety from fire of any building unless the greatest care is taken in its construction, and on no account to think that any deficiency in that particular will be made up by carefulness in its occupation and management.

The points which I think is most useful to notice are the following :—

(1.) The structure and arrangement of buildings generally.

(2.) Certain legal and other provisions for preventing loss of life in dwelling houses.

(3.) Certain legal and other provisions for preventing loss of life in factories.

(4.) Certain legal and other provisions for preventing loss of life in public buildings generally.

(5.) Certain legal and other provisions for preventing loss of life in theatres and music halls.

To be Continued.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

THE "Hotel Nevills," illustrated in this number, which was opened to the public last April, is situated on an elevated site at the terminus of the Sierra Railway, Jamestown, Cal., and was built by Capt. W. A. Nevills of the famous Rawhide Mines, for the Jamestown Improvement Company, from designs by and under the supervision of George Rushforth, architect, of Stockton, Cal. The building which is mainly "frame construction" was begun and completed for occupancy within a period of four months, and in the winter time. The size of the building is 74 feet by 184 feet, two stories in height and attic, containing in all sixty five rooms. The exterior is treated in the Japanese style of Architecture, which is admirably suited to the mountainous landscape surrounding it. The verandahs are 10 feet wide, and extend almost entirely round the building, the lower part of verandah columns also the house base 4½ feet high, are constructed with variously colored "quartz" taken out of gold mines in the neighborhood, and is put up in random rubble fashion; between this and the second-story the walls are covered with steel lath and cement in imitation of ashlar stone. The main floor consists of large reception hall and office, dining room, seating 200, billiard room, bar, barber shop, kitchen, etc., a section of the building nearest the depot being fitted up for the Wells, Fargo & Co's offices and baggage rooms.

Upstairs are the general parlors, private suites with bath-

rooms and toilets, bridal suites, etc., the hallways having exits to balconies.

The principal rooms have large open fireplaces, but the building is also furnished with the gravity system, hot water heating, with direct radiation put in complete by Jackson & Carle of Stockton, who are making a growing reputation for this line of work. The house is lighted by electricity and is wired for return call and fire alarm bells, in fact the entire building is equiped with all the essentials of a modern hostelry. The cost of the building being close to $30,000.

The building was constructed by Robert Powell one of the best established contractors of Stockton.

The Stockton Lumber Co., Joseph Fyfe manager, furnished all the sash, doors, millwork and stairs, their headquarters are at Stockton but have branch establishments located at Jamestown and other parts of the State.

The plumbing and tinning was done by Geo. F. Schuler of Stockton.

Morrell & Mitscher, wood carvers and cabinet makers of Stockton, were engaged to put in the elaborate office and saloon fixtures, they also make a specialty of this class of work.

F. T. Riley of San Francisco supplied all the plaster staff and Japanese characters on the building and E. T. Burrows & Co., Chas. J Waterhouse, San Francisco, agent, furnished the "Copbronze" screens throughout the building.

PAINTING IRONWORK.

THE painting of ironwork is one of the most neglected yet important factors in its preservation and one to which the mechanical engineer rarely devotes much time or thought. The majority of specifications merely state that the iron work is to receive one, two, or three coats, as the case may be, ignoring entirely the quality of the paint. Perhaps the engineer is not wholly to blame for this, as the manufacturers of paint, like other vendors of special articles, puff their rival wares, until everyone, except the expert, is quite at a loss what special paint to choose. As a general rule, price is the first thing which influences the choice of paint, after which comes color, and finally covering power. The preservative action is seldom considered, whereas if this were kept prominently forward, we should have had exhaustive experiments on the subject and some consensus of opinion as to the proper paint to use for ironwork, one which would thoroughly preserve it under the most adverse circumstances, thereby saving the loss due to oxidation.

A paint to preserve ironwork should possess great firmness, good hardening properties; it should be elastic and expand and contract readily with the iron at varying temperatures. Of the best paints those most used are the oxide of iron and red and other colors of lead paints. Oxide of iron paints possess greater covering power than lead paints in the proportion of three to two. From some experiments which have been made with some of Wolston's Torbay oxide of iron paint, it was found that on a surface of ten superficial yards it took for the first coat of oxide, 1 lb.; for the second coat, 1½ lb.; for the third coat, 2 lb.; whilst with the lead paint 1½ lb. were used for the first coat, 2½ lb. for the second coat, 3½lb. for the third coat. It is claimed by the makers of paint from natural oxides that these oxides possess some mysterious advantages over artficial oxides which have been obtained as by-products from chemicals, that the paints from artificial oxides do not possess good covering powers, that they have not the power of amalgamating with oil, and that they have an acid reaction which necessarily corrodes the iron. This may be the fact in some cases, but we have seen artificial oxide paints which have none of these disadvantages, and which have a decided alkaline reaction, thus equalling, if not rivalling, the natural oxide paint, and being made from waste products, they are necessarily cheaper. A good paint for iron work should be free from grit, uniform in quality, unchangeable under atmospheric influences, possess great covering powers, and be of an alkaline nature. The whole of these qualities can be tested by the ordinary painter under proper supervision, except the last, which requires chemical knowledge; and we should strongly recommend the users of paint for ironwork to test their paints in conjunction with a qualified analytical chemist who has made the subject his study.

Before painting the surface of galvanized iron it should be washed by an alkaline solution, as the galvanized iron frequently has a greasy acid surface when it leaves the galvanized bath. In painting constructional ironwork the wrought iron should be allowed to weather first before painting, as the oxide which forms on the surface of the iron when rolled will always, sooner or later; peel off, carrying whatever coats of boiled oil or paint there may be put upon it. We have seen this oxide peel off in flakes 2 ft. and 3 ft. square; we know that engineers are fond of specifying the iron to be oiled whilst hot from the rolls, and we have even seen it specified that castings should be coated with boiled oil whilst red hot. How the gushing engineer expected the castings to be fettled and cleaned before this operation we know not. A good coat of paint improves the appearance of a machine, bridge, or roof, and although it may seem a minor matter, yet we believe there is money to be saved by careful attention to the quality and price of the paint used on ironwork.—*Mechanical World.*

VALUABLE INFORMATION CULLED FROM OUR EXCHANGES.

CONSIDERABLE dissatisfaction has been manifested in Chicago over the requirement, by the new building ordinances, of the consent of all property owners in a residence block to permit the erection of a building to be used for any

other purpose than that of a dwelling. Sixteen buildings are delayed as a result of this provision, and it is probable that an effort will be made to amend the ordinance by only requiring the consent of the majority of the property owners. As the ordinance now stands any person desiring to erect a business building in a block, where one-third of the existing structures are residences, must secure the written consent of every property owner of both sides of the street in such block. In several cases, one property owner has seen a chance to secure compensation for his consent and has refused to approve of the subject. As a result the plans are tied up in the city building department, and will not be approved until unanimus consents have been obtained. If an attempt is made to amend section 49, it is likely that the commissioner will recommend that livery stables be stricken out of this section, and that they be placed under the same restrictions as spitals.—*The Construction News.*

MR. J. Morton Brydon, the architect who has been selected Mr. Akers-Douglas to design the larger of the two new Government buildings to be erected at Whitehall, has been in conference with the authorities recently, and his plans will shortly be completed. Mr. Brydon is a Scotsman by birth, but his main work has been in London. He designed the Women's Hospital in the Eustonroad, the Free Library at Chelsea, and recently extended the Municipal Building at Bath. The authorities seem to have departed from the ordinary mode of selection. When the Law Courts were projected there was a competition which resulted in the present buildings. Mr. Akers-Douglas, it is understood, consulted the Royal Institute of British Architects, who submitted twelve names, and from these the two architects were adopted.

THE SECOND architect is Mr. William Young, one of best known names in connection with great buildings. He will be responsible for the offices to be built on what is often spoken of as the Carrington House site—that is, the piece of land which has for so long a period been vacant between Whitehall Buildings and Whitehall, and exactly opposite the Horse Guards. Mr. Young has earned an almost world-wide reputation by the Municipal Buildings in St. George's square, Glasgow, which are even more notable for their interior arrangement than for their striking and picturesque exterior. A more recent work by Mr. Young was the erection of Lord Wemyss's seat in Scotland. For the new War Office Mr. Young has an admirable site.

AN idea of the amount of material required in the construction of a modern office building can be secured from the following figures furnished by Charles McCaul, who has charge of the construction of a 16-story skyscraper in Philadelphia.

About 8000 cubic yards of excavations, 4000 yards of concrete and stone masonry, 4,371,555 pounds of steel, 300,000 pounds of ornamental iron, 36,000 pounds of ornamental bronze, 10,000 cubic feet of granite, weighing 900 tons, 260,000 square feet of fire proofing, weighing about 3600 tons, 1360 tons of patent mortar used in plastering to cover 42,000 square yards of plastering; about the same amount of cement mortar used in brick and stone masonry; 40,000 square feet of Pevonizza, Numidian and Italian marble; 15,000 pounds of nails, 10,000 cubic feet of terra cotta, weighing about 290 tons; 325,000 face brick, 1,500,000 common brick, 24,000 sq. ft. of glass, weighing about 73,660 pounds; about thirty miles of electric piping to encase the electric wiring throughout the building, and about ten miles of plumbing and steam-fitters' piping. There were on an average 200 men working on this structure from the start until the finish.

THE PROTECTION OF IRON FROM RUST.

THE use of paint as a protection from rust is so general that to attack its efficacy seems almost a heresy, and yet it is well known that the protection it affords is only partial, and that, in spite of many and frequent coats of paint, iron work will rust. A leading article in *The Engineer*, in discussing this subject, shows that there are many good reasons why paint should not be an efficient protecting material. The pigment contained in a paint possesses no protective value in itself, dependence being really placed upon the liquid matter alone; hence, in using heavy coloring matter, assuming that the proportion of oil per square foot remains constant, the engineer is simply pay ng more money for a substgnce not only of no service, but positively deleterious to the rest of the material.

Linseed oil, however cannot be used alone, since it expands on drying, and the resulting glm is apt to be rugose; moveover, if the adhesion of the oil to the metallic service is not perfect, it may cause the production of blisters. The lack of stability possessed by the solid body resulting from the oxidation of the oil also causes it to crack and fall to pieces; hence as a protection against rust it is not successful.

Varnishes have beeu suggested, but many of them are apt to crack and peel, or else are so porous as to permit moisture to penetrate. A few varnishes are free from these defects, bnt there cost renders their use for this purpose impracticable.

Better results in many ways are obtained by the use of such materials as tar, pitch, or asphaltum, and, although they may not altogether respond to the demands of the ideal specification, they will be found to possess many serviceable qualities. Coal tar has been charged with possessing a corrosive action upon iron, although this action is said to be prevented by heating with lime; but pitch, softened with creosote and dissolued in one of the cheaper light oils recovered during distillation, or in a corresponding petroleum derivative forms an excellent protective varnish.

Asphaltum dissolved in a spirit solvent is also suggested as a safe and suitable paint for the protection of iron work, and this may also be used in connection with linseed oil for a second coat. This, indeed, seems to form the ideal combination. The iron should first be cleaned from all scale or rust, and every trace of moisture removed, after which a thick priming coat of pure boiled linseed oil is applied, and carefully worked into all cracks and crevices. When this has become perfectly dry and hard a second coat of black varnish, composed chiefly of pitch or asphaltum should be applied, the combination forming the best protection against rust at present available.

Probably in this connection the use of the sand blast for obtaining a thoroughly clean surface would greatly assist the protecting medium by enabling it to make a perfect contact with the surface of the metal.

TRADE NOTES.

The Keuffel & Esser Co. of New York are without doubt the leaders in America of drawing materials and surveying instruments. They carry a most complete and assorted stock and their goods are recognized as of standard quality all bearing their trademark. Architects and surveyors should send for their illustrated catalogue as they will be sure to find something that they are in need of. See advertisement on page iii.

EXPERIMENTS OF THE BEHAVIOR OF CAST-IRON COLUMNS IN FIRE.

BY H. SCHULER.

(Abstract from Deutsche Bauzeituug, 1897, in Proceedings of the Institute of Civil Engineers, England, Vol. CXXIX, p. 407.)

IN CONSEQUENCE of the warehouse fire in Hamburg in 1891 the Senate of the city caused experiments to be made with wrought-iron and timber stanchions,* which were continued in 1895, with cast-iron columns 10 feet 8 inches long, 10½ inches diameter, and 1¼ inch or ½ inch metal, centrically or eccentrically loaded, with or without fire-proof casing. They were finished with spherical ends and placed upright, gripped by the two halves of an oven, two yards high, swinging on door-hinges and containing twelve gas-burners which emitted flames at least a yard high. A hydraulic press was below the column and its cross-head above it. The oven was furnished with apparatus for measuring heat, etc., with peep-holes and with the nozzle of a fire-engine. On an average a load of 3.2 tons per square inch, with a red heat of 1400° F. obtained in thirty-five minutes, produced deformation in a centrically loaded column without casing, which showed itself by bulging all round in the middle of the heated part, especially where the metal happened to be thinner; fracture occurred finally in the middle of the thickest point of the bulge. If the load was less this occurred at a higher temperature, and *vice versa*. Jets of water had no effect until deformation heat was reached. The casings tried were of Monier structure, of patent "Korkstein," of asbestic silicious marl and of asbestic cement. These had the effect of increasing the time, till deformation heat was roached, from thirty-five minutes to four hours or five hours, with a measurable temperature of 2,000° F. to 2,500° F. The best result gave a casing of asbestic silicious marl, as a temperature of 2,000° F. was maintained for seven hours, and the deformation diagram justified the conclusion that the column might have stood two hours longer. It is the most expensive casing. The greater thickness of metal in the columns had comparatively little effect on the time, but on the whole a thickness not less than 1¼ inch seems advisable. Ventilation through the column had a beneficial effect. The behavior of hollow cast-iron columns, even without casing, is superior to that of ordinary wrought-iron stanchions.—*M. A. E.*

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street,
SETH BABSON, Pres. H. A. SCHULTZ, Vice-Pres.
OLIVER EVERETT, Sec. JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.
THEO. A. EISEN, PRES. ARTHUR B. BENTON, Vice-Pres.
WILLIAM C. AIKEN, Sec't. AUGUST WACKERBARTH, Treas.

WASHINGTON CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.
JOS. C. HORNBLOWER, Pres. JAS. G. HILL, Vice-Pres.
E. W. DUNN, JR., Sec. W. J. MARSH, Treas.

ASSOCIATION OF ARCHITECTS OF ARIZONA, meetings held at Phoenix, Arizona.
D. W. MILLARD, Pres. T. H. MADDOX, Vice-Pres.
W. R. NORTON, Sec. and Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.
E. J. MOLERA, Pres. W. F. C. HASSON, Vice-Pres.
OTTO VON GELDERN, Sec. EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.
JAS. E. BRITT, Pres. J. L. E. Firman, Sec.

BUILDERS' EXCHANGE, Directors meet first Friday in each month at Mission and New Montgomery.
S. H. KENT, Pres. JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday evening of each month.
ADAM BECK, Pres. M. V. BRADY, Sec.

KEELY MOTOR UP-TO-DATE.

PROCEEDINGS OF ENGINEERS' CLUB OF PHILADELPHIA

BY E. J. SCOTT, ACTIVE MEMBER.

[CONTINUED FROM JULY NUMBER]

AN INTERESTING experiment of a different character was made in the third room. The apparatus stood in the northwest corner on a table with a glass top. It was a large ball covered with gold foil mounted upon an axis upon which it revolved stiffly and was considerably out of balance. It looked like an old timer. The two investigators stood by the apparatus while Keely went into the middle room and looked through an aperture, just large enough to show his face, across the room to the ball. From the axis of the globe ran a thread of black silk to Keely and was attached to a zither. Keely said the ball would turn round once, twice or any number of times the visitors might name. One was suggested, and Keely struck a chord on his instrument and the ball turned over once. Three was called, and another chord resulted in its rolling over three times, and so on with other numbers, or it would roll rapidly when so indicated. It went with a wobbling motion and seemed to be rubbing on something. When it stopped it stopped suddenly. It was also noted by

LEVITATION EXPERIMENT

the visitors that the same number of turns did not necessarily require the same chord on the zither.

The great machine for navigating an air-ship also stood in this room. It had wheels not made to revolve, but only to be set to certain combinations. It was covered with resonators, sensitized disks and spiny scales, and had on the end of a large shaft a gong, or Kladna, as Keely called it, which when struck created as much dismay as a fire-ball in the night. This machine, which weighed tons, Keely said would rise like a feather by creating about it a vibratory condition which annihilated gravity. He was understood to say that this same apparatus had been moved about eth room in that very way.

After these three visits Mrs. Moore was plainly told by the two gentlemen that they had seen no evidence of any new force in any of the experiments shown by Mr. Keely. In fact some of them were readily explainable by the laws of nature already known, and no doubt, with proper facilities for investigation in addition to what the eyes alone had afforded, they would be able to explain them all.

Soon after this Mrs. Moore arranged with Professor W. Lascelles-Scott, of London, to come to Philadelphia and examine the apparatus and be instructed by Keely in the secrets of its operation. He arrived in this city in March and entered upon his investigations. Mrs. Moore said to the writer that the Professor was to be allowed to handle and take apart the apparatus, which was a greater privilege than had been allowed to any priot investigator.

There was naturally great curiosity to know what opinion the English scientist would form. He was unknown to the scientific world on this side of the water, but to the writer he said he was "late consulting expert to the India Museum under Dr. Forbes Watson, and lecturer on chemistry and physics to the London Conservatoire." From this it would appear that he had some reputation in his own country, and would be entirely competent, with the facilities afforded him, to pass a proper judgment on Keely's invention. The Professor pursued his inquiries for fully a month before he made any public expression of his views, and it was with great interest that the members of the Franklin Institute, at at the monthly meeting, held April 15th, listened to his remarks.

He stated in brief, that he had commenced to get a glimmering idea of Keely's great principle, which was based upon vibrations, a subject with which the Professor declared himself thoroughly familiar, as he had devoted much attention to it, and had published some of the results of his investigations in that branch of physics. He had, he said, been quite unable for some time to understand Keely's explanations, as they were made in language too unscientific, the terms used being unintelligible, because, although the words were familiar, Keely had used them out of their generally accepted meaning, giving them a signification known only to himself, and possibly to Mrs. Moore. The Professor stated, however, that it was his opinion that "Keely had certainly discovered a means of utilizing a force that has been suspected, but has never been realized in any form." He could say it was neither magnetism nor electricity, either static or in the form of a current.

In saying so much the Professor stated that he told less than he knew. He promised, after he had more fully investigated the matter, to come again before the Institute and tell the result of his study into Keely's secrets. That promise was never fulfilled.

About a fortnight after the Franklin Institute meeting, Mrs. Moore sent for the writer and said that Professor Lascelles-Scott has arranged an experiment which would convince him that he was entirely wrong in his surmises as to the force used in experiments already witnessed, and named Saturday afternoon, May 2d, for a meeting at Keely's laboratory.

On that day there were present Mrs. Moore, Mr. Elliott (a friend of Mrs. Moore's), Professor W. Lascelles-Scott, E. A.

Scott and Mr. Keely. It has been assumed that the writer believed that the platinum wire, connecting the sympethetic negative transmitter with the "vibrodyne" or engine, carried a current of electricity, and the Professor had arranged for a delicate test to show that not the faintest current could be detected in the wire. The mere statement of the object of the experiment was sufficient, and Mr. Scott said he granted the conclusion at once and without experiment, as he had no thought that the wire was used as a conductor of electricity. The wire had been wound in its center, into a small coil of a dozen or more turns, and within this coil it was pcoposed to insert a rod of soft iron, which the Professor stated had been chemically prepared, so as to produce the best results. Keely had himself made this coil and when the Professor carelessly took the wire in his hand to explain it, Keely nervously took it from him, saying it might become broken and that he had wound it with great care. The writer, as on former visits, was not permitted to handle anything, and was repeatly cautioned not to do so. He used his eyes, however, to the best advantage in examining the coil which it had cost Keely so much trouble to wind, to see the evidences of its being a tube, and in the flattening at certain places, the tendency to bend at an angle at others, and its general tendency to bend in the form of a polygon instead of a circle when being wound, there was no reason to doubt his former convictions that the "wire," which seems to be an inseparable abjunct to Keely's apparatus generally, was a thin platinum tube. This latest experiment only afforded additional proof of what was quite well known before.

On one of the visits with Mr. Burk, the writer picked up one end of the platinum wire which had fallen on the floor at the end of an experiment, and held it up so that Mr. Burk could see that it was a tube.

Following his general policy at all these visits, the writer did not avow his belief. A question indicating doubt or a statement of a discovery made would have prevented him from seeing other experiments where he might obtain further confirmation of his views. When Mr. Elliott, who had never before seen any of Keely's experiments, began to ask questions, which both the Professor and Keely answered, the writer asked the privilege of making some stenographic notes, which Keely had permitted on a former visit, and he occasionally asked a question himself on points not well covered by the other questions. This conversation brought out the description of the construction of the "sympathetic negative transmitter," which forms so important a part of the whole system, and without which but few experiments are made. The Professor's description in his own words was, that "it is a hollow globe, the axis of which (a cylinder 1½ inches in diameter) is retractible within certain ranges; that is, it is drawn out or thrust into the globe by turning it like a screw. That axis carries a sensitive disk, called a kladna, which is sensitive to vibrations of every kind, and especially to those vibrations which are inaudible, beyond the voice to utter or ear to perceive. Therefore Keely is quite right when he calls it a sensitive disk. Beyond the kladna is a series of resonators, on this same central axis, and when it is screwed in or out the kladna and the series of tubular resonators (which resemble small organ pipes) go backwards and forwards, and occupy different positions in this globe, sometimes central, sometimes a little to one side and sometimes a little to the other side."

Keely said the moving of the disk inside is to get one way the attraction and the other way the repulsion. He added to the description: "There is also a sympathetic scale, formed of straight wires of different length struck around the edge of a disk, which represents progressive chords, the same as in a piano. This scale is placed on the axis, between the kladna and the resonators, and all are fixed on the central axis. On the outside of the globe is a similar scale, which to a certain degree corresponds to the scale on the inside. There is also another smaller scale on the outside, which has two series of spines or wires. I might use three of these spires for one experiment and half a dozen at another. There is no regular interval of sound between any two of the spines; they vaay one-quarter tone to one-half tone and sometimes a full tone. The larger scale has about seventy spines."

The above description by the English scientist and Keely is all that is known of the interior construction of the "sympathetic negative transmitter." The only apparent use of the axis or handle is to shift the position of the kladna, the resonators and the spines to a greater or less distance from the center of the globe by turning it backwards and forwards.

Keely than exhibited his levitation experiment, or the floating of heavy weights in a jar of water, which the writer had seen on each of his three former visits. He noticed that the jar was a new one and had a different cap or cover from the one he had before seen. The Professor explained that, at his instance, Keely had taken a new jar and that it had been filled with distilled water. He said he was familiar with the general principle of the experiment. Two weights similar in every respect to the weights used in the old jar, were reposing on the bottom, the one, a disk-shaped flat brass box, without a cover, filled with amalgam, and the other, an orange-shaped globe, said to be filled with shot. In answer to the writer, Keely said these were not the same weights which were used in the old jar; the globe, however, had the same indentations and the gold-foil with which it was covered the same spotted appearance which had been particularly noted at his former visits, and the desk seemed to be the very same, although there were no distinguishing marks by which it could be absolutely identified.

The Professor had carefully weighed these weights before they were put into the jar and that the flat disk weighed 68 ounces and 387 grains in air, and 58 ounces 383 grains in distilled water, a difference of 10 ounces and 4 grains, which represented the water displaced. The globular object weighed 53 ounces 3 4 grains in air, and 45 ounces 362 grains in distilled water, a difference of 8 ounces 22 grains. The jar appeared somewhat smaller than the old one, and was 41 inches high, and perhaps 10 inches in diameter. The cover was of glass, and was sealed on with a white cement. A space from one-half to three quarters of an inch was left between the surface of the water and the glass cover. Inserted through the cap was a plug, with a binding screw for attaching a wire. The jar stood on a small, cheap table, with a thick, glass top. Keely placed the sympathetic negative transmitter on the same table, and connected the top of the jar with it by means of the platinum wire. On the top of the jar he placed a disk similar to the one in the jar.

When every thing was ready, Keely turned the handle or axis of the sympathetic transmitter, twanged some of the wires of his scale, blew softly on the mouth-organ, and the round weight started for the top, followed a few seconds later by the disk-shaped weight. In answer to the writer, he said he could not reverse the order of their rising. The

tone of B natural, he said, started the first one to go up, and B flat the second one. He struck a tuning-fork for the purpose of subdividing those notes, he said, and setting a chord for their descent. Then, again turning his handle, and blowing upon his mouth-organ, the disk-shaped weight came down first at the end of about three minutes, the other remaining at the top for a time. He said he could arrest it before it reached the bottom, but failed to do so, and it struck the bottom and bounced up and down three or four times before it finally settled itself. Afterwards, he sent both to the top, and then sent the disk to the bottom, leaving the globular weight at the top, where he said he could make it stay ten years. After about three minutes, with blasts upon the mouth-organ, and turning the handle backwards and forwards, the ball was sent to the bottom, where it struck and bounced up about four inches.

The writer found by jarring the table with his knee, which he did several times unobserved, he could make the weights bounce up 3 or 4 inches without the aid of the sympathetic negative transmitter, the mouth-organ or the "chord of mass," which was rather remarkable, when the specific gaavity of the weights, as given by Professor W. Lascelles-Scott, is taken into consideration. It was an experiment in vibrations which were quite visible, though inaudible, and which produced results that did not demand for their explanation the theoretical force of "apergy."

At this point the Professor gave as his general conclusion on this levitation experiment of Keely's, that if Keely were to take a standard barometer, a standard thermometer, and a standard electroscope, and take the condition of the air at the time of making an experiment, and would also have his scales graduated in precise tones, which they were not at present, than with the barometer reading for instance at 29.5, the thermometer at 55.5, and the electroscope at .26 with a certain response note and chord of mass, and a certain note struck upon the sensitive sympathetic transmitter, he could at all times raise the weights to the top without feeling his was as at present: and another note would as certainly send them to the bottom. This, he said, was the first time he had unbosomed himself so far; but that was his opinion, founded upon what he had seen there. Keely replied that we were just beginning to learn sound sense.

To be Continued.

MANAGEMENT OF QUICKSANDS IN FOUNDATIONS.

TWENTY-FIVE years ago, anticipating that I would probably have to contend with quicksand in my work, I read up on the subject everything that I could find, but with very little satisfaction. In fact the theories set forth by the majority of writers on the subject were virtually of no use when I met with the actual facts in the course of my experience. I investigated the matter very thoroughly, however, finding a very essential point in the fact that in all quicksands a great variety exists in the sizes of the atoms, this variation requiring various plans to be tried to successfully contend with the difficulties that must be overcome.

I did not have long to wait before meeting with a quicksand bottom. I was then engaged on the foundations of the bridge work of the D. L. & W. Railroad, in Hoboken. In foundation east of Henderson street we had to go two feet into a bed of quicksand to get our depth. In this case it happened that I had a large bank of oyster shells in the way, which I utilized. I cribbed my sump large enought to give me plenty of room, mixed the oyster shells with gravel, and put a bed of the mixture all around the sump, shoveling the sand out of the middle and allowing the mixture to sink until I got below the required depth; the mixture closing in and making a solid bottom for sump. After this I uncovered about ten feet square section of the sand, throwing out the sand as quickly as possible with as many men as could conveniently handle a shovel. The moment the required depth was reached we covered the bottom with a foot of the gravel and shells. When this was done and walked over, it would all be in a movement, but after standing a few hours it would become perfectly solid. The cause of its becoming solid is that the larger atoms of the sand passing up through the mixture adhere to the shells, gradually closing up all the crevices. Leading drains across the foundation we successfully completed the work. After this I used crushed stone with better results than with the gravel.

Some years later when superintending the construction of a large tank—200 feet in diameter—for gas holder in Brooklyn at thirty feet in depth—just the depth we had to go—we uncovered a quicksand bed. The contractor was very much excited, having previously lost several thousand dollars in a similar case. I proceeded this time with crushed stone in getting my sump down, sinking a wall of broken stone all around the well hole, got our pipes into their proper depth and made this our sump, leading box drains from this point all over the bottom, uncovering sections of ten feet square and replacing with crushed stone a foot thick, completing the whole bottom of this system with entire success.—*J. B. Gordon in Stone.*

CONCRETE STAIRS.

CONCRETE STAIRS, owing to the hardness and nature of the aggregates used, are apt to become slippery on the treads. Various methods, such as grooving, inserting wood or lead cubes in the concrete, have been used to render the treads non-slippery. Grooving has the defect of retaining dust, while lead or wooden cubes are difficult to replace when worn out. These defects have been entirely overcome by the use of rubber cubes which are made in the form of a screw, so that they can be raised when they become worn, and when finally worn out they can be readily extracted and replaced by new ones. Most people are aware that a staircase always becomes worn in the centre, while the ends are never trodden upon, inasmuch as it is impossible to tread within 7in. or 8in. of the wall or handrail. Therefore the rubber cubes in the centre of the tread wear out first. Being made to unscrew they can be changed from one position to another until they are all worn out, when new ones can be had. The rubber cubes not only render the treads non-slippery, but afford a firm, noiseless surface.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

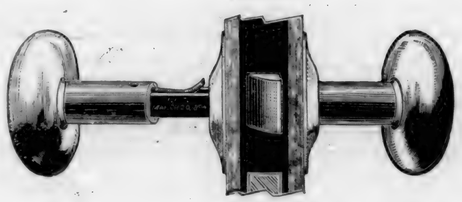
SPECIFY



THE WEATHERWAX

Patent Screwless Door Knob.

Plans and Specifications Invited for an Hospital Building.

Public notice is hereby given to architects that competitive plans and specifications for the erection of an hospital building will be received by the Board of Supervisors on MONDAY AFTERNOON, September 12, 1898.

The proposed building to be of modern design and to be constructed of stone or brick, or of both, with all the latest scientific improvements.

The said hospital building to be erected on the lot of land commencing at the most southeasterly corner of a tract of land known as and designated, on the official map of the city and county of San Francisco, as the "Almshouse tract."

The said plans and specifications to be so prepared that the cost of the building shall not exceed in the aggregate the sum of three hundred thousand ($300,000) dollars.

The architect whose plans are adopted will be appointed architect and superintendent of the building, and will be required to give a good and satisfactory bond to insure the completion and construction of the said building for the amount of the cost as made by the said architect. The architects submitting plans determined by the Board to be second, third and fourth in merit will receive premiums of $1000, $750 and $500 respectively, with the understanding that any features of said plans and specifications which may be considered useful or necessary to be embodied in he plans adopted may be used without urther cost of charge.

JNO. A. RUSSELL, Clerk.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

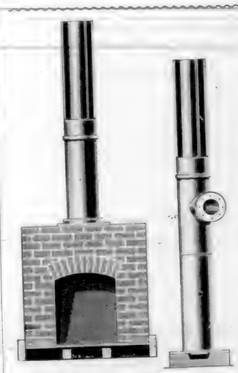
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET, SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See **CLAWSON'S LIVE VENTILATOR.** It is as much better than a dead one, as a live man is of a dead man.

Price, $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

CLAWSON'S PATENT THIMBLE.

For Sale by CHARLES J. WATERHOUSE, 421 Market Street, San Francisco.

To our Customers and Friends on the Pacific Coast.

Through frequent complaints made to us, we have learned that unprincipled and dishonest dealers on the Pacific Coast have counterfeited our trademark numbers and substituted inferior, spurious goods as ours, when ours were distinctly ordered, thus defrauding their customers and injuring our trade and reputation.

Our goods are acknowledged to be the best, and are fully warranted by us, and are marked with our name or initials or with our well-known trademark and catalogue numbers.

We request direct notice if any goods alleged to come from us, or bearing our trademark or numbers, prove to be other than the best, and perfect in every respect, as we will follow up and expose such frauds for our customers' and our own protection. We have no exclusive agents on the Coast, but our goods are obtainable from all respectable dealers in drawing materials, stationery, hardware, artists' material, etc.

Respectfully,

KEUFFEL & ESSER CO.,

LOS ANGELES

The following prospective buildings are reported by real estate dealers and are given for what they are worth:

Mrs. Florence Maynard has purchased a lot on the east side of Bonnie Brae, between Ninth and Tenth streets, upon which she intends building a residence to cost between $4000 and $5000.

Charles Shaw intends to build on the west side of Breed street between Fourth and Fifth streets.

F. Stavnow is about to build a cottage on Westlake avenue. The contract has been awarded to F. M. Caler.

M. B. Thompson has purchased a lot on East Fourth street, between Chicago and Breed streets, on which he intends to erect an eight room residence roam. He is also about to build a cottage on Star near Pico.

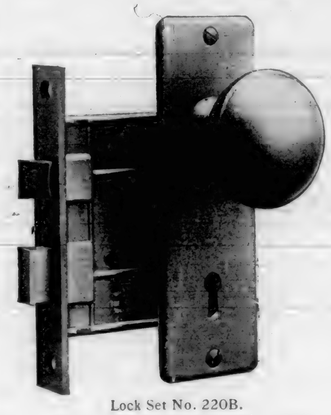
Architect Geo. H. Wyman is preparing plans for two frame buildings to be erected at the Soldiers' Home; one of which is designed as quarters for the women nurses and the other as a bakery building.

J. C. Gladden is about to commence the erection of five or six two-story residences on Westlake avenue, between Tenth and Eleventh streets. Architect A. L. Haley is doing the preliminary work on the plans. These buildings, like numerous others of the same class, are built for speculation.

Continued on page xii.

The "Vulcan" Locks

All Wrought Metal—with "Compensating" Hubs.



Lock Set No. 220B.
One-half Actual Size.

Our General Offices in New York have recently received the following unsolicited letter from a prominent builder and contractor. Believing that the statement of experience it contains will be of interest, we reproduce it below.

An Artistic Brochure on Vulcan Locks, also a Catalogue of 90 pages, will be sent on request.

The Yale & Towne Mfg. Co.

LOCAL OFFICE:
Mills Building, San Francisco.

GENERAL OFFICES: 9-11-13 Murray St., NEW YORK.
WORKS: Stamford and Branford, Conn.

OFFICE OF A. BEINHAUER,
124 Maiden Lane,

NEW YORK, July 11th, 1898.

The Yale & Towne Mfg. Company,
9-11-13 Murray Street, New York.

Gentlemen:-Having lately had occasion to use and apply your "Vulcan Locks" in the Anderson Building, 12-14-16 John Street, I take pleasure in mentioning the fact that in the application of these locks there is a large saving of labor as compared to the ordinary CAST-case locks.

The difference, as I found it, was that while a man put on six to eight of the latter, he could in the same space of time put on twelve to fourteen "Vulcan Locks," thus decreasing the cost of labor to a considerable extent.

Another feature about these "Vulcan Locks" is that while they give as good service as any cast-case lock of their denomination, they do not require as much cutting away of wood in the lock-rail, thereby strengthening the door to an appreciable extent.

Wishing you all success with your "Vulcan Locks," I remain

Yours truly,
(Signed) ALFRED BEINHAUER.

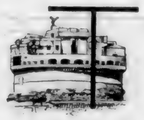
A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

NOTICE is hereby given that Mr. Tom M. Grant is no longer connected with this Journal.—E. H. Burrell, Lessee and Publisher.



HERE is not a law upon the statute books of this State as to which there is such widespread dissatisfaction as what is commonly known as "the mechanics' lien law." This dissatisfaction is not confined alone to the owner of property as to which a lien is to be enforced, but it extends to those for whose protection it was supposed the lien law was designed. In the constitution of the State, and in the statute as enacted, there is no cause for complaint. The trouble has come from judicial legislation, which has made the constitution of the State, and the statute passed in pursuance of it, fall short of their purposes. The language of the constitution is plain and simple. In fact so plain and simple that, to the mind of the layman, it seems impossible that there should be any room for construction that would result in judicial legislation. The constitution says—"Mechanics, material men, artisans and laborers of every class, shall have a lien upon the property upon which they have bestowed labor or furnished material for the value of such labor done or material furnished."

To the ordinary reader, this would mean simply that a man performing labor upon and furnishing material for a building, would have a lien to the full extent of the value of the labor performed and the material furnished. But the Supreme Court of this State, not long after the adoption of the Constitution, said, and still adheres to the decision, that this language does not mean what it says, and has added

the following proviso: "Provided the value of such labor done and material furnished shall not exceed the contract price therefor."

Had the Supreme Court left this provision of the Constitution undisturbed, and had not added this proviso, the lien law of this State would have been a very beneficent thing and could have injured no one. In that case, it would have been generally known and understood by the owner of property when contracting for the erection of a structure upon it, that the property would be security to the full value of all labor performed upon and material furnished to it, and he would have protected himself against all liens, by exacting from his contractor a good and sufficient bond. Who would have been hurt then? The laborer and the material man would have gotten their money in full, and the owner would not have been hurt, because he would have been protected by his bond.

Now, however, under this addition made to the provision of the Constitution by the Supreme Court, we are all at sea, and there is not a greater delusion and snare than the mechanics lien law. The laborer and material man are injured, because they so frequently have to accept a pro-rata. This position forced by the decision of the Supreme Court is out of consideration for the owner of the property, and yet, as we have shown, if the provision of the Constitution had been followed by the Court, the owner would not have been injured, because he would have been protected by his bond. But now, when neither the owner, the laborer or material man would have been injured by following the provision of the Constitution, the owner is allowed to defraud the laborer and the material man by getting their labor and material for nothing.

Under the decisions of the Supreme Court, things run along in the building line about as follows: An owner concludes that he wants a structure put upon his property at a cost of $10,000. He goes to his architect, and the architect makes his specifications and draws his plan for such a building, and advertises for bids. When the bids are opened, it is found that some irresponsible contractor has offered to furnished the labor and materials and erect a building according to the plans and specifications for $6000. This bid is accepted. Things go smoothly until towards the end, and all at once the property is plastered with liens. In a rage, the owner goes to his lawyer and complains in bitter terms of the position into which he has gotten. The lawyer quietly waits until he get through fuming, and then smiles and says:—"What are you kicking about? You have gotten a $10,000 house for $6000, and the laborers and material men have paid for the difference between the $6000 and $10,000. In other words, you have been given $4000 of other peoples labor and material." This brings a change over the spirit of the owner's dream, and he goes away satisfied at having made such a fine speculation.

Now, this robbery which the owner is allowed to perpetrate, as we have said, would never have been permitted if the Supreme Court had followed the Constitution of the State, and had left it as it was adopted. The laborer and material man would have been paid in full, the owner would have paid the value of his house, and no more, the bond protecting him against any excess over the contract price.

It is a pity that the building interests of this State have been led into such a quagmire, when, as we have said, the Constitution is plain and simple. The Constitutional convention intended to protect the laborer and the material man, and the protection that it gave to them was without any injury to the owner—the Constitutional Convention, knowing that the owner could protect himself by a bond from the contractor. It is doubtful if the Constitution could ever have been adopted at the time that it was if the people did not understand that this provision had been inserted for the protection of the laborer and the mechanics and material men, and that the building classes had obtained more than a shadow and a delusion by a constitutional provision inserted on their behalf. It is no answer to this to say that the laborer and material man could protect themselver by sitting down and figuring up the cost of the job, and thus finding that its cost would go beyond the contract price. It is not to be presumed that the hod-carrier upon the Crocker Building, in course of construction, nor even the ordinary material man, would be capable of sitting down and figuring upon the cost of marble brought from over the seas for the purposes of that building.

This is not all. The Constitutional provision also intended that the lien referred to by it should be speedily enforced. We have not space in this issue to discuss the practice in regard to the enforcement of this lien. This phase we will defer until our next issue. Then, we propose to call attention to the difference between the practice of our Courts and the provision of the constitution in reference to its speedy enforcement.

THE statement of an influential morning paper that architects were to be shut out from all competition in the designs for a new County Hospital and that the authorities having this important matter in charge, have already selected an architect whose designs were accepted in advance, bears the impress of truth.

No reputable architect ever enters into a competition for municipal buildings but feels that, no matter how meritorious the plans are that he may submit, some one with a "pull" is sure to bear off the honors and emoluments, leaving him with his designs upon his hands and all his labor, time and calculations, thrown away.

This condition of affairs is disheartening to the last degree, not only to the architectural profession but to citizens at large, who would have this great avenue of municipal benificence a credit and not a disgrace to the city, whose revenues they provide. This branch of charity and which involves the citizens of San Francisco in a very large annual expenditure, is one they share without complaining of the heavy cost. By rights, the very best care of the impoverished sick should be given. A hospital of the vast extent required by this city should rank with the best of those supported by sectarian, national or private munificence, and the first thing to be considered is a building fitted with all the appurtenances for healing the sick and caring for the convalescent that modern science has indorsed. No board of supervisors is competent to decide upon the best qualifications for a great public hospital. Such bodies generally lack the experience and education necessary for the selection. Neither are medical experts altogether infallible, though their opinions are entitled to great weight. No plan should be adopted without having been submitted to the judgment of a competent, broadminded and unbiased committee of architects. A combination of architects of ability, scientific physicians and surgeons and practical builders should be employed whose decision should be final.

Moreover no architect who has a decent regard for the ethics of the profession should accept a decision in his favor that comes from underground sources and in defiance of all appearance of good faith towards other members of the profession.

It is said, the specifications have been withheld from all architects who desired an open competition in the plans, and this charge is apparently sustained.

For the good name of the city of San Francisco and in behalf of other cities of the state who so closely follow our examples, this publication protests against any methods in the choice of hospital plans which are not open and above board, in which each and every competing architect is allowed an equal opportunity of winning. Public opinion asks nothing more. It demands that much *at* least.

THE semi-annual meeting of the Builders' Exchange on Monday the 19th was one of the most important that this great organization has ever called together. The several reports of the officers indicated a very satisfactory condition of internal affairs and a promising outlook for the future. At this meeting the Builders' Exchange placed upon record its official indorsement of the national policy of retaining those countries which the valor of our army and navy has won from Spain. Without qualification, the sentiment of the Exchange was decidedly in favor of holding the rich islands of the Phillipines and West Indies and adding them to the domain of the United States. The unanimity with which the proposition was adopted is significant and in conjunction with the action of the Chamber of Commerce, Board of Trade and other commercial organizations, indicates that a great majority of the people of California view with favor holding tight what our troops have won. The Builders' Exchange as representative of the intelligent bone and sinew of the country can not be charged with selfish motives in advocating this addition to our national territory. Unlike Commercial bodies they have no trade interests to bias their judgment.

The several speeches were brief and pointed and reflected great credit upon those who made them.

THE NEW COLUMBARIUM OF THE ODD FELLOWS CEMETERY ASSOCIATION OF SAN FRANCISCO.

By ALEX. F. OAKEY.

THE ODD FELLOWS Cemetery Association of San Francisco has shown the courage of its convictions, in providing handsomely for permanent disposition of incinerated remains, in a Columbarium that in design and execution has the dignity and repose of a grand mausoleum, and the solidity of a fire-proof structure.

The capacity is likely to be equal to the requirements of at least fifteen years, when similar structures may be erected to realize a grand scheme of architectural effect, enclosing a court or *Campo Santo*, with connecting peristyles, that are suggested by the treatment of the existing mass. The demands upon the adjacent crematory have already necessitated the building of an additional furnace. The first incineration

CREMATORY, ODD FELLOWS CEMETERY, SAN FRANCISCO.

at this crematory took place on June 26, 1895, and the increase since that date has been constant.

The Odd Fellows crematory is one of twenty-eight institutions of the kind in operation in the United States; and

INTERIOR VIEW OF CHAPEL, CREMATORY.

many more are organizing. Cremation was abolished in Europe about 400 A. D., and it was not till 1658 that any intelligent agitation of the subject was revived; and not till

Milan in 1874. Since when the practical interest in this method of disposing of the dead has steadily and rapidly increased all over the world. There is still much religious and

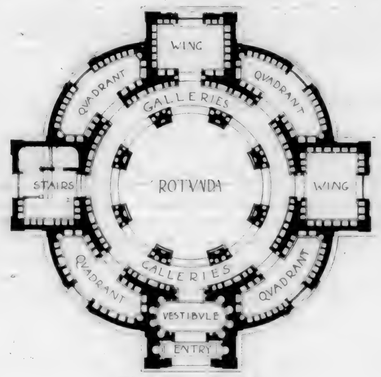
INCINERATING ROOM SHOWING EMPTY CARRIAGE RETURNING FROM RETORT.

sentimental prejudice opposed to incineration, but these do not seem to be so vital as was at first supposed.

The Theosophists insist upon scattering the ashes of the departed upon the waves of the ocean, as a rite illustrating the inevitable return of all matter to its constituent elements: the absorption of all entity in the universal whole. But most of us prefer to have some consecrated spot, some special receptacle, marked more or less emphatically and appropriately, as a record of the dead and preservation of their memory.

The Columbarium erected by the Odd Fellows Cemetery Association of San Francisco provides this spot and permanent receptacle; and while it has all the quiet expression of endurance characteristic of a beautiful church, it is at the same time a cheerful, well lighted and appropriately decorated place.

The fundamental design in plan is a Greek cross, the arms terminating in massive porches. This rectangular scheme is at once relieved and enhanced by the intersection of the sweep of the great circular wall that is concentric with the inner rotunda walls. These walls are the essential features of the whole design both in effect and in construction; and in the treatment of the problems involved in carrying the dome Messrs. Cahill & Condon, the architects, have especially shown their skill and judgment. In one sense the construction of the dome is concealed, in as much as it is carried on a system of steel ribs, each rib com-



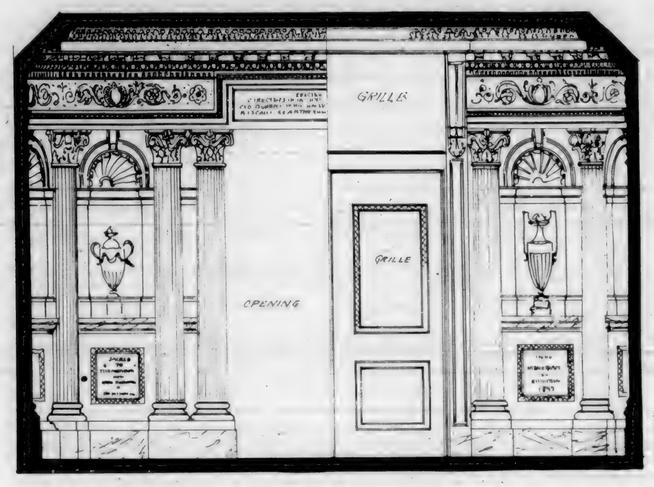
FLOOD PLAN.

posed of two members spreading apart at the shoes to rest on the inner rotunda wall and the next outer concentric wall, or drum. But these ribs determine the actual forms of the inner and outer domes, which may be considered as the covering of these bones rather than any attempt to conceal them.

In other respects the construction is very simple, but is remarkable for the fearless and intelligent employment of concrete and cement throughout, on a scale unprecedented in this part of the world. It will be seen that in no other material could the necessary honey combing of all walls

FRONT ELEVATION

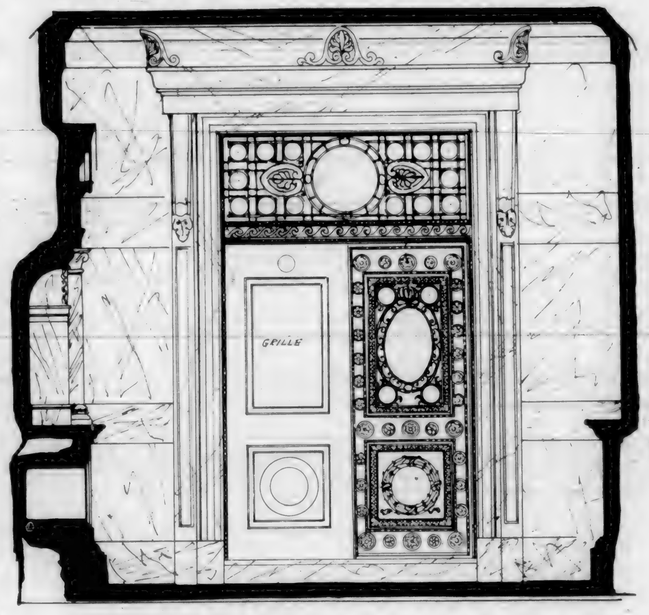
with nitches have been so easily and safely accomplished. The use of copper to encase the great piers of the rotunda is



HALF SECTION LOOKING
INWARD OUTWARD

not only an agreeable relief from the surrounding whiteness, but a practical provision against possible injury to the angles in the constant passage to the corridors. And the mosaic floors have many practical advantages besides their expression of permanent richness. Throughout this interior wherever marble or metal is best for the purpose to be served it will not be found wanting. As to the design as a whole or in detail it repays study. The first impression from the approach is that of simplicity and purity inherent in Greek design, but any suggestion of paganism is obviated by the cruciform plan and the dome above, which indicates the centre of the cross and suggests a unity of purpose. On closer examination we find in every disposition and detail some enhancement of the general purpose: and it cannot be many years before the open nitches in the vestibule and those in the piers of the rotunda, shall be occupied by busts of persons of distinction, whose ashes are contained in some beautiful urn resting in the surrounding walls.

If the abolition of cremation by the early Christians resulted necessarily from their insistance on the resurection of the body, the modern Christian has come to see that such literal interpretation of scripture would exclude from salvation the holy martyrs who suffered at the stake; and that it is the better part of man: his ideas and ideals that are immortal. The Greek names of the winds and the constellations over the portals to the alcoves in this Columbarium are a happy reminder of the imperishability of ideas; keeping the living in constant sympathy with the great majority; with nature and with nature's God.



OUTER VESTIBULE AND DOORS

MEETING OF THE BUILDERS' EXCHANGE.

ON Monday, the 19th inst, the largest and most enthusiastic meeting of the Builders' Exchange in the history of that influential organization was held. A special call had been made by the President, S. H. Kent, Esq., for a large attendance, that, in addition to the customary semi-annual assemblage and the reception of the usual reports of the officers, an expression should be made of the sentiments of the organization on the retention of conquered Spanish territory in line with the San Francisco Chamber of Commerce, State Board of Trade, the Manufacturers' Association

COLUMBARIUM, I. O. O. F. CEMETERY.

and other commercial and industrial bodies. Over two hundred members were present.

The President's report showed a total membership of 252 and a condition both prosperous and harmonious. An invitation was extended to all who had any objections or grievances, relative to the management of the Exchange, to state them but there were no responses and Secretary James A. Wilson, proceeded to read the report of the Treasurer which showed total receipts during the six months ending September 1st of $1619.28 and expenditure of $2170.50, also of resources, consisting of money in bank or out on interest

INTERIOR VIEW OF DOME, COLUMBARIUM, I. O. O. F. CEMETERY.

with personal property, all amounting to $7063.95. The reports were referred to the proper committees when the President announced that Hugh Craig, President of the Chamber of Commerce, James W. Kerr, of the Manufacturers' Association and Oscar Lewis, ex-president of the Builders' Exchange would address the meeting on the subject of retaining the Philippines.

Hugh Craig was the first and he was received with great applause: "History," remarked the speaker, "tells us what the result of acquiring new territory means to nations ambitious for expansion and powerful enough to hold, protect and develop them. The gospel of acquisition is not a new doctrine to the people of the United State. The original thirteen states began expansion very early in the history of this country. Florida, Louisiana, California and Alaska and finally Hawaii were all the fruits of that destiny, or Providence, which seems to be directing us in the course to be pursued in the far east. The Philippines, number it is said 1400 islands, separated by deep channels of the sea and contain from 8,000,000 to 10,000,000 people. They measure over 100,000 square miles in area and grow luxuriously all the fruits of the tropics. The soil is rich and exhaustless and their stores of coal, iron, precious metals and valuable woods has never yet been estimated. They are well watered and grow sugar, tobacco, hemp and other commodities which we cannot produce ourselves, more profusely and more cheaply than any where else upon the face of the globe. The harbor

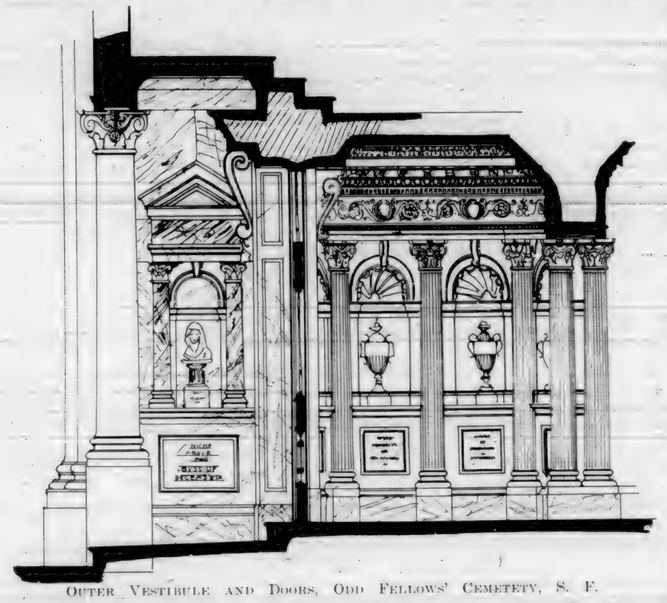
of Manila is unsurpassed in extent and situation and is only a few hundred miles from that coast where one-half of the human race exist. There would be no question whatever if the Philippines were located close to our own coast or even as near as the Sandwich Islands. The 7000 miles that separate them from the United States is now easily bridged by submarine telegraphs and rapid steamships. If, under the mediæval rule of Spain, the Philippines produced such royal revenues as are reported, what would they not do under our enlightened laws and influence? As Hawaii has increased in richness and productiveness under our tutelage so would the Philippines. We bring 1,500,000 tons of sugar from Europe and other foreign countries, with the Philippines our own we need not bring a ton. The people who inhabit these islands are the objection, they never can assimilate them, it is argued, but who wants to?



Outer Vestibule and Doors, Odd Fellows' Cemetety, S. F.

They are a bright race and are said to make good laborers. Under fair, equitable laws they would make a contented, happy people. The cost of administering the islands is urged as an objection yet the last report is that the custom receipts of Manila, since the American occupation has not only paid all expenses but left a surplus of over half a million."

Mr. Craig complimented the exchange on the innovation of holding an open discussion upon this important subject.

Mr. James W. Kerr, President of the Manufacturers' Association made the next address which was listened to with profound attention:

"The acquisition of that great territory so far from our own shores," said Mr. Kerr, "is contrary to the traditional policy of this government. Forced into a war to deliver an abased and persecuted people from the tyranical government of Spain, the emergency rests upon the people of the United States to decide what disposition shall be made of this conquered territory. Commercial interests are unaminous in the wish to permanently retain them as our own. They see in the future a rich traffic flowing to and from these islands and opportunities for the accumulation of great wealth. These mercantile classes represent eastern manufacturers whose only interest is to find new and profitable markets for their fabrications but the wage earner sees in the acquisition a reopening ot the Asiatic question whereby the cheapest labor in the world may come in direct competition with themselves. Certainly this class of people, in numbers the large majority, are entitled to as great, if not greater consideration than the rich manufacturer. If this question of labor, which has been pending for so many years, is to be still farther complicated by the introduction of this Philippine element then a serious objection to the retention of those islands is presented. If these Asiatics who have shown such an aptitude for our methods of manufacturing, with their habits of living which our laborers cannot imitate or follow, then a serious injustice will be done our people by the possibility of their being compelled to compete with goods made in our own territory by the cheapest labor in the world. The difficulty which Great Britian escapes by reason of its more flexible constitution might be full of danger to the United Stateswith a constitution adopted only for our own people." Mr. Kerr instanced the manufacture of jute bags, which were once only made in Belfast, but were now a monopoly of Calcutta, owing to its cheap labor. "The United States is responsible for a good government for the Philippines. The question involved is difficult to solve. The consequences ofa retention of the Philippines might do California the greatest injury."

Oscar Lewis opened his remarks by facetiously remarking that, "one of Mr. Craig's recommendations for the Philippines was that those islands produced indigo"—"We don't require any indigo here, business in this Exchange is so bad that we do not need any indigo to dye us a deeper hue then we are"—at which there was great laughter and applause.

Mr. Lewis was generally in favor of keeping the Philippines though he too regarded the possibility of danger from the cheap labor competition of the islands with our own.

Brief remarks were made by Robert Mitchell, L. J. Dwyer, Martin Kelleher, James A. Wilson and others, for and against the question.

The following resolutions were then offered by James A. Wilson and carried with the utmost enthusiasm and without a dissenting voice:

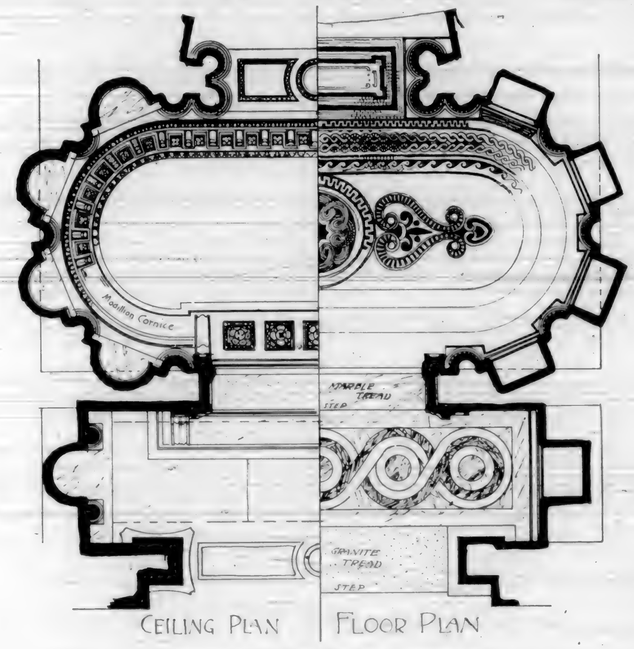
Whereas—"The Builders' Exchange of San Francisco, animated with a sentiment of patrotic pride in the achievements of the Army and Navy of the United States and believing that what has been acquired in our war with Spain should be retained for the welfare of humanity in general and the United States in particular, therefore, be it resolved

that we petition the President of the United States to use every honorable means to retain the Philippines islands and other territory over which the stars and stripes now float by right of conquest.

"Be it further resolved that the early completion of the Nicaragua canal is essential to the welfare and prosperity of the people of the United States.

RESOLVED—"That a copy of these resolutions be forwarded to the President of the United States."

Before adjournment a vote of thanks was given to the speakers by a rising vote.



CEILING PLAN FLOOR PLAN

COLUMBARIUM, ODD FELLOWS' CEMETERY.

LESSON FROM FIRE AND PANIC.

WITH respect to the structure, the party-wall as a separation between buildings is, I think, effectual if no illegal openings are made in it. Whether or not it need be carried up through the roof has been a question, but no satisfactory evidence seems to be forthcoming as to the stoppage of fire by party-walls that are not so carried up. When the London Building Bill of 1893 was before Parliament, the Committee took a great interest in this question, and decided that the old height of fifteen inches above the roof should be raised in the case of a warehouse to three feet.

As to openings in external walls where the streets or back areas are narrow, we want shutters that will delay the passage of fire from without, if only for half an hour, and will obstruct the passage of fire from within. It may be that fire-resisting blinds occupying little space will be found useful. The common lighting areas are formed by what are supposed to be external walls, and the provision of shutters or blinds to the openings in them is even more necessary. Every contrivance of this kind should be actually closed every night.

"I am quite unable to understand the slow progress made in this country by the fire-resisting floor. In Paris fire-resisting floors were common five-and-thirty years ago. I was then carrying out such work here on a large scale, but the case was exceptional; the weight of the floors was great, the walls had to be thickened, and the cost was excessive. Cheap steel and light substitutes for concrete have changed all that.

In the Cripplegate fire, although many of the warehouses were modern, and some had already been burnt out once or oftener, there was not a single fire-resisting floor. There were wooden floors carried on iron girders, but we are familiar with the behavior of wrought-iron girders under such conditions. They expand and contract so as to overthrow the walls, or they become soft so as to hang down like tapes. There are now available fire-resisting floors in great variety in which the iron is more or less protected from the fire. In using them care must, however, be taken that no leakage of gas can accumulate in any hollow spaces. I have seen a large and handsomely decorated house in which fire-resisting floors were used in conjunction with battened walls. Upon applying a light in the usual way to the suspected point of escape the mixture of gas and air accumulated in the hollows exploded, and the ceiling with the wall battening in two stories was stripped away, littering the floors and mixing

with the broken window glass. In that case there were also severe personal injuries.

In the great re-housing schemes of the London County Council I have made every floor fire-resisting by the use of steel joists wide-spaced, and filled in solid with coke breeze concrete upon which the floor-boards are nailed, the plastered ceiling being done under the concrete direct. The cost is no more than that of a good wooden floor, while the total thickness is only seven inches, which saves two or three inches in the height of each story. They are not complained of by the tenants in respect of noise, but in a house where this would be of great consequence a cork covering to the boards under the carpet would be a sufficient remedy.

If it is necessary to adopt wooden construction for floors, the ordinary pugging should at least be used. Joists of double the usual thickness placed two feet apart, and filled in solid with some form of concrete, would offer great resistance to fire. As to the material for pugging, coke breeze and cement concrete, mixed four parts to one, stands fire and water better than anything else. In Switzerland they use coarse plaster stuff, into which long wet shavings have been stirred as hair is stirred into plaster for ceilings; and this, though an imperfect substitute for concrete, will resist a fierce fire for a considerable time, but more experience is required in the use of light solid materials.

I think we have now arrived at a time when architects should at least try to secure an incombustible roof. This is stipulated in the building leases of some very important London estates, and I am told that it raises no difficulty. If the space in the roof is wanted, pugging or concrete is sometimes put between wooden rafters. If a steep roof is necessary, sheets of asbestos put on the roof boarding in place of felt will afford some protection. In a building professing to any degree of fire resistance, the roof should be protected by a ceiling of concrete put over the topmost storey. Ceiling on perforated or expanded metal will give some protection against a small fire.

As to partitions, lath and plaster should be quite abandoned, and brick-nogging also, for a half-brick wall in cement is as easily constructed. There are many kinds of thin partitions from which to choose. I commonly use coke breeze cement concrete two inches in thickness, which is light, tough, and strong enough for stories of the ordinary height. Old lath-and-plaster partitions may be filled in with this material or with brickwork by removing the plaster from one side only. If the structure is otherwise fire-resisting, any wooden panelled partitions may be considered as fixtures and disregarded, particularly if in hard wood.

I mention these and similar details, not as being unknown, but as being too often neglected, even where the cost would not be a serious item. If fire-resisting materials were in more regular demand workmen would become familiar with them and they would cost less. Exaggerated estimates of the cost of fire-resisting construction do much harm. Very important steps can certainly be taken in that direction with very little extra cost on ordinary construction.

The great danger of a staircase arises from the cupboard underneath its lower flight, which will probably be stored with combustible materials. If it is constructed of thin deal it will take fire easily. If more solid or made of hard wood it will resist a small fire for some time. If it is to be fire-resisting, concrete is safer than stone. But if everything about a staircase is incombustible it may be rendered useless by accumulated smoke arising from such a cupboard as I have mentioned, or from an adjoining room.

There are certain precautions necessary in construction whether the materials are fire-resisting or not. I have already suggested the danger of hollow floors and hollow partitions, but all hollow spaces that can contain gas or transmit flame or inflammable vapor, or will even allow a supply of air to pass towards a fire, are highly dangerous. The lining of walls with matchboarding is the most ordinary case of this kind. By means of it fire communicates instantly all over a shop, and up through the floor to the rooms above. The hollows formed in heavy plaster cornices and the hollow spaces behind skirtings transmit flame or inflammable air without any outward warning to adjoining or even distant rooms. One instance or two will illustrate this.

In a fire near Clapham Junction that originated among the Christmas decorations in a draper's window, the smoke and flames passed in this way to the upper floor so quickly, that two girls at work over the back part of the shop lost their lives, although there was an easy means of escape by getting out of the back window on to a flat. In a similar case several persons, probably seized with panic, jumped from first floor windows into the street, instead of stepping out at the back. These are indications of the quick effect of fire in a badly-constructed building.

As to the passage of fire or inflammable vapor by hollow spaces, cases have happened where the origin of a considerable fire was inexplicable until it was traced back to some source at a considerable distance from the scene of the damage. In a "fireproof" building, a workman hung his coat in a cupboard leaving his pipe in the pocket. The coat took fire and fell, setting light to the skirting, behind which a small hole had been left in the brick internal wall. The floor-boards of the adjoining room had been laid on wooden rips that stood above the service of the concrete. The fire passed along the hollow space, doing three thousand pounds' worth of damage in this "fireproof" building. Unless the elasticity of a floor is an object, the boards should be nailed down on to a surface of coke breeze concrete.

If no more serious measures than those I have described are taken in respect of a purely domestic building, they may give very material security as to its behavior in case of fire. For many years past companies have been erecting artizans' dwellings in London, one of them having put up blocks containing nearly six thousand tenements. In only one case has a fire in any artizans' block extended from one tenement to another. This is due to generally careful construction, though there has been no rigid adherence to fire-resisting principles.

In these descriptions of the parts of a fire-resisting building, the work of the carpenter is practically excluded, and there are many buildings in which this principle should be carried out. There is, however, much convenience in the use of timber, and if posts and girders are made in large sizes, they are safer than if made in iron. Solid floors made of deal joists set close together withstand fire for a long time, but are ultimately destroyed by great heat.

Many attempts have been made to render fir timber fire-resisting or slow-burning by chemical treatment or by covering it with paint. Some of these applications are useful when applied to textile fabrics and to thin slips of wood, but I have been unable to meet with any process that renders the mass of a joist or beam fire-resisting throughout. This is a matter well worth further inquiry and experiment, for joinery at least might be protected in this way. As to the public experiments sometimes reported, those in which tar

or mineral oils are liberally used are untrustworthy, for these are light-giving and smoke-producing liquids, and do not imitate the conditions of an ordinary fire.

Although we may succeed in rendering new buildings satisfactorily fire-resisting, a much more important question for the present generation is the improvement of the condition of old buildings. This is well worth the attention of those who have the charge of building estates already covered, of ordinary town property, or of those old historic mansions filled with family treasures, one of which as I write has been added to the number of those wrecked by fire. In an ordinary buil ding, purely domestic, if the joints are not strong enough to carry a filling in of concrete they will carry ordinary pugging, and if no morethan a breadth of three or four feet all round a floor is well filled in on some fire-resisting system, every hollow behind adjacent cornices, skirtings, and partitions being carefully stopped, a very considerable amount of resistance to fire will be afforded. If, besides, the points of contact between chimney stacks and floors and roofs be examined and timber cut away, the condition of an old house might be made approximately as good as that of a new building. In certain cases, where in London a domestic building is changed into a public building, and where a building partly domestic and partly used for trade is increased in area, something of this kind has now to be done.

To be continued.

ON THE SALINE EFFLORESCENCE OF BRICKS.

THE CAUSES LEADING TO IT, AND THE PRACTICAL MEANS OF AVOIDING THE SAME.

BY OSCAR GERLACH (PH. D., BERLIN.)

CONTINUED FROM LAST NUMBER

BURNING

THE efflorescences produced by the sulphates in the green brick or during the water-smoking are always visible on the surface of the burnt product, either in the form of whitewash or in that of minute warty, crystalline kernels. On the other hand, the burnt products may come from the kiln faultless in appearance and without a visible trace of coloration, and yet conceal in their interiors considerable quantities of sulphates, which, when the bricks are later wet by water, are dissolved and make their appearance at the surface. These salts arise always during the burning,—not before,—and are particularly annoying because of their usually appearing first in the finished building, where, through the effects of rain and frost, they gradually are drawn to the surface.

Hitherto the opinion has been erroneously entertained that, in *burning*, only the sulphurous acid gas due to combustion participates in the formation of whitewashing sulphates, whereas the undisintegrated iron pyrites still remaining in the clay was left entirely unnoticed. Now Dr. Hans Guenther, of Carlsruhe, has recently shown by a series of instructive experiments that also the iron pyrites *in the clay* participates in the formation of whitewashing sulphates during the burning; and this is readily intelligible when we reflect that the sulphurous acid gas, produced by the combustion, must act mainly on the surface of the bricks and can only gradually penetrate into their interior, whereas the combustion of the finely distributed iron pyrites in the brick itself brings the generated sulphurous acid gas into immediate contact with the finely distributed carbonates of the clay, and so renders possible a perfect absorption of the acid by the carbonates.

The formation of whitewashing sulphates during burning takes place as follows:—

A part of the sulphur in the iron pyrites (FeS^2) is very loosely combined with the iron, and oxidation of this part begins at approximately 650 degs. Fahr., whereas the other part burns only at red heat. The products of the disintegration are oxide of iron (Fe^2O_3) and sulphurous acid gas (SO^2). Expressed in chemical formulæ, we have:—

$$\text{I. } FeS^2 + 2O = FeS + SO^2$$
$$\text{II. } 2FeS + 7O = Fe^2O^3 + 2SO^2.$$

The sulphurous acid gas SO^2, when heated in contact with solid porous bodies, is oxidized by the superfluous oxygen of the air of combustion to sulphuric acid, or converts existing oxides into sulphuric salts. It was for a long time erroneously believed that the presence of water or of water vapor was necessary to the formation of sulphates; but as early as 1856 Plattner in his book, *Der metallurgische Rost-process*, demonstrated experimentally that sulphurous acid gas in combination with the oxygen of the air and in contact with minute particles, or in contact with porous solid bodies, oxidizes to sulphuric acid, and that the water vapor in the air was not of consequencs for the formation of this acid. If the minute particles or porous bodies are or contain oxides, these oxides are converted into whitewashing sulphuric salts. The following of Plattner's experiments is of special interest to the brickmaker. He conducted a mixture of sulphurous acid gas and atmospheric air, once wet and once dry, over some unslacked lime (CaO) in a glass tube. At red heat the lime was converted into calcium sulphate ($CaO+SO^2+O=CaSO^4$) without a trace of sulphurous acid or sulphuric acid being noticeable at the free end of the tube. All the sulphurous acid, accordingly, was absorbed by the lime and converted by the oxygen of the air into sulphate of calcium. The same experiments were made with other oxides with the same results.

In the burning of clay products the same conditions prevail, provided the fuel contains sulphur and the clay contains carbonates of calcium, of magnesia, or of alkalies—which is to a greater or lesser extent usually the case. At red heat the carbonates, liberating their carbonic acid, are converted into their respective oxides, which, being finely distributed throughout the porous brick by the oxidizing action of the air, combined with the sulphurous acid gas to form whitewashing sulphates.

To turn these laboratory experiments to account for practical brickmaking, the experiments were made on a large scale. Different clays were burnt with different fuels, and

the amount of sulphates contained in the products determined both before and after burning.

EXPERIMENT I. *Clay alone contains sulphur.*

Material. Clay containing both iron pyrites and a small quantity of carbonate of lime.

Mode of Burning. Red heat (about 1650 to 1750 degs. Fahr.). Gas furnace. Oxidizing flame. The gas employed showed only the merest traces of sulphur. A kilogram of the *unburnt* clay contained 0.584 grams $CaSO_4$. *Result.* Since the fuel contained no sulphur, the *fivefold* increase of the amount of whitewashing sulphates in the burnt product must have been *entirely due to the presence of the iron pyrites in the clay.*

EXPERIMENT II. *Both the clay and the fuel contain sulphur.*

Material. Same clay as in Experiment I.

Mode of Burning. Red heat. Coal fuel. Oxidizing flame. Coal contained 3 to 4 per cent FeS^2, or iron pyrites. The amount of sulphates was determined in *several* different burnt bricks. A kilogram of the burnt clay contained on an average 12.76 grams $CaSO^4$.

Result. A more than *twenty-fold* increase of the whitewashing sulphates.

EXPERIMENT III. *Fuel alone contains sulphur.*

Material. Clay free from iron pyrites, but containing much carbonate of lime.

Mode of Burning. Red heat. Fuel, coal, etc., as in Experiment II. One kilogram of the *unburnt* clay contained 0.483 grams $CaSO_4$. One kilogram of the *burnt* clay containing 16.85 grams $CaSO_4$.

Result. An almost *forty-fold* increase of white washing sulphates.

EXPERIMENT IV. *Clay and fuel free from iron pyrites (at least containing traces only).*

Material. Same as in Experiment III.

Mode of Burning. Gas furnace. Oxidizing flame. Red heat. One kilogram of the *unburnt* clay contained 0.483 $CaSO^4$. One kilogram of the *burnt* clay contained 0.621 $CaSO^4$.

Result. A very *slight* increase of whitewashing sulphate.

EXPERIMENT V. *Fuel free from iron pyrites. Clay containing great quantities of iron pyrites, but only traces of carbonate of lime.*

Material. Clay containing large quantities of iron pyrites, but almost free from carbonate of lime and other carbonates.

Mode of Burning. Gas. Oxidizing flame. One kilogram of the *unburnt* clay contained 0.321 grams $CaSO_4$. One kilogram of the *burnt* clay contained 0.510 grams $CaSO^4$.

Result. A *very slight* increase.

EXPERIMENT VI. *Fuel and clay both contain iron pyrites, but the clay shows only traces of carbonate of lime.*

The materials and the results were the same as in Experiment V.

CONCLUSION.—It follows from the above experiments that the whitewashing sulphates are formed in large and annoying quantities only when sulphurous acids and carbonate of lime, or other carbonates, *occur together* in chemical action. Sulphurous acid has no injurious effect on clays containing no carbonates of lime, magnesia, or alkalies. Such clays, accordingly, can be burnt with sulphurous coal without any fear of an increase of whitewashing sulphates, whilst clays containing carbonate of lime require a fuel free from sulphur.—*The Briekbuilder.*

KEELY MOTOR UP-TO-DATE.

PROCEEDINGS OF ENGINEERS' CLUB OF PHILADELPHIA

BY E. J. SCOTT, ACTIVE MEMBER.

[CONTINUED FROM LAST NUMBER]

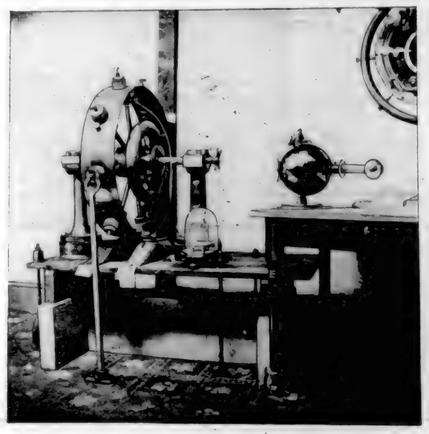
FROM what has already been explained, it will be at once evident that the rise and fall of the weights in the jar of water is due to their varying specific gravity. The weights sink, because they are heavier than the water, bulk for bulk; they rise because they are lighter than an equal volume of water. Keely's weights were so balanced that a slight difference in the air-pressure in the enclosed space above the water would make them rise or fall by changing their size sufficiently to make them of less or greater specific gravity. This is easily accomplished by having some portion of the weight compressible. It is a child's toy. Keely's transmitter, containing compressed air, was capable of increasing the air-pressure in the jar by turning the handle or switch to some point which would connect the jar with the reservoir of compressed air, or diminish the pressure by a change of the switch which would connect the jar with the open air.

Keely, whose eyes were always on the weights, shut off the switch as soon as the weights either rose or fell. With great skill and by letting in the air very slowly, he was sometimes able to leave one weight at the bottom, the other going to the top, or even to send one of them down after it had partly risen. It was particularly noted, however, that the one which always sunk first was the only one which he could arrest in its upward movement. Indeed, he replied to the writer's inquiry on that point, that he could not make the other go down first. He might have done so between the visits of the same investigators by changing the relative specific gravity of the weights. His explanation of his inability to do this was made in such terms of the new science that, while it sounded all right in the ear, it conveyed no meaning to the listener. It may have been stupidity on the part of the visitor. Indeed, when Keely heard of his explanation of the experiments, he said that he "considered that the Professor's testimony outweighed Mr. Scott's suspicions, and he did not think it necessary to do anything to convince him of his ignorance."

The Keely motor, or engine, is the last of the long series of Keely's inventions, of which the apparatus before referred to are only experimental studies. The word "vibrodyne" was coined by Professor W. Lascelles-Scott, as being more nearly expressive of the character of the character of the machine than "dynamo," which Keely had used. It is supposed to embody the principles which Keely has labored so many years to establish. He says it is operated directly by "apergy," a force hitherto unknown, existing in nature and only waiting to be utilized; that it consists, like light, in the extremely rapid vibrations of the ether, or matter infinitely divisble which pervades the universe; the problem being to devise apparatus which will respond to these vibrations. The vibrodyne may be thus described:

A heavy cast-iron bed plate, supported eighteen inches above the floor by an iron slab at each end, bolted to the floor at each of the four corners by heavy iron rods, and braced from the side wall, forms the foundation for a machine which can be prevented from running by the pressure of a finger, or stopped when at full speed by grasping it with one hand.

A flat brass ring about four feet in diameter is supported on two wooden slabs resting upon the iron bed plate, which are held to it by brass straps. On the outside of this ring, at equal distances apart, are fastened clusters of short tubes, each about a half-inch in diameter and three inches long, forming resonators. These tubes are partially filled with amalgam, or stopped up with diaphragms at varying distances from the ends. They are called resonators. There are nine of these clusters on the circumference of the ring, and on the outside of each is a hollow binding post, to which wires can be attached. On the inside of the ring, immediately opposite the resonators, a "sensitized disk" is attached, similar in appearance to the heavier weight used in the jar experiment (a brass cover filled with amalgam). On



THE VIBRODYNE OR KEELY MOTOR.

the inside of this disk is another binding post similar to the one outside the ring, which is also hollow, and making an open passage between the inside and outside binding posts. There is thus a set of nine binding posts and disks pointing inwards, which are connected together by the mysterious platinum wire which figures in nearly all the experiments. The outside resonators and inside disks are about two inches apart.

Concentric with and inside of this ring is the revolving wheel. Its axis is supported at each end upon large iron pillars much enlarged at the bearings of the axle. A large hub in the middle of the axle has radiating from it eight spokes, one less than the number of opposing disks on the inside of the flat ring. These spokes do not terminate in a rim, but on the end of each is a disk similar in size and character to those which project inward from the ring. There is upon the axle near the hub a heavy iron ring about fourteen inches in diameter, which revolves with it, presumably as a balance wheel to make a steady motion. This ring had been added at some time between the last two visits, probably at the suggestion of the Professor.

On the occasion of the last visti Keely set the wheel revolving in the following manner: Taking a 10-inch sympathetic negative transmitter (the large brass ball) he placed it on a table having a glass top, on one side of the room, and connected it with the vibrodyne by a platinum wire, attaching one wire to the binding post of the transmitter, and the other to the binding post projecting from a resonator on the top of the vibrodyne. Then, snapping some of the wires on the scale of the transmitter and turning the handle backwards and forwards, the wheel commenced to revolve, slowly at first and with gradually increasing speed, until the revolutions were about 180 per minute.

The Professor asked: "Am I right that you can stop the wheel by withdrawing that kladna?" (The kladna on the axis would be withdrawn by turning the axis or handle of the transmitter in one direction.)

Keely said "yes," and appeared to turn the handle about twenty times, and, snapping one of the wires, which he said was note B, the wheel slowed down, and finally stopped.

He started the wheel again as before, and said: "As the machine now revolves the subdivision is 42,800 to the second. That is disintegrating vibration. I could disintegrate quartz with that vibration and powder it into dust." He did not offer to powder any quartz in that way, however.

Keely suggested that he could stop the wheel in several ways, two of which he illustrated. He pulled the wire out of the binding post of the transmitter, and it stopped as before. Again starting it, he stopped it by pulling out a plug in a hole in the binding post on the machine, the hole being a continuation of the hole into which the wire was thrust on the other side. This left the transmitter attached to the machine, and gave the writer an unexpected opportunity to further confirm his belief that the so-called platinum wire was a small platinum tube. He had noted on his first visit that the method of attaching the wire to a binding post was peculiar. The post was in form like a T and was hollow. There was no screw to hold the wire in place, but the ends of the wire terminated in plugs which were pushed into the end of the hollow arms of the T. On this occasion he observed that not only the horizontal arms of the T, but also the perpendicular leg, were hollow, leaving a passage down into and through the resonator, the flat ring, the sensitized disk on the inside of the ring and the binding post upon the disk, to which was attached the platinum wire before described, which encircled the interior side of the flat ring.

On the present occasion the writer took his seat next to the revolving wheel, not following Keely's suggestion to take another position. When Keely pulled out the plug from one arm of the T, leaving the wire sticking in the other arm, the other end of the wire still being connected with the sympathetic negative transmitter, he moved his face close to the hole left by the plug, which had been pulled out, and distinctly felt a blast of air from the tube (or "wire").

To make certain that the air current did not come from the revolving spokes, he kept his face in the same position until the wheel had stopped, and still felt the full force of the blast of air from the tube.

Here then was a confirmation of his belief that the wire was a tube carrying compressed air, the reservoir of which was the 10-inch globe of the "sympathetic negative transmitter." It was evident, however, that a sufficient amount of power to run the wheel for any length of time, or to run it at all, could not be stored in a globe of that size. He did not believe that it was so run, but that the air pressure performed the office either of an automatic switch-closer or automatic pole-changer on an electric circuit. This belief was to some extent confirmed by an oracular remark of the Professor to Mr. Elliott, to whom he said: "The wire does not supply the power, but it unlocks the power which runs the wheel." The writer at once said to him: "Professor, you have exactly expressed my opinion."

To be Continued.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

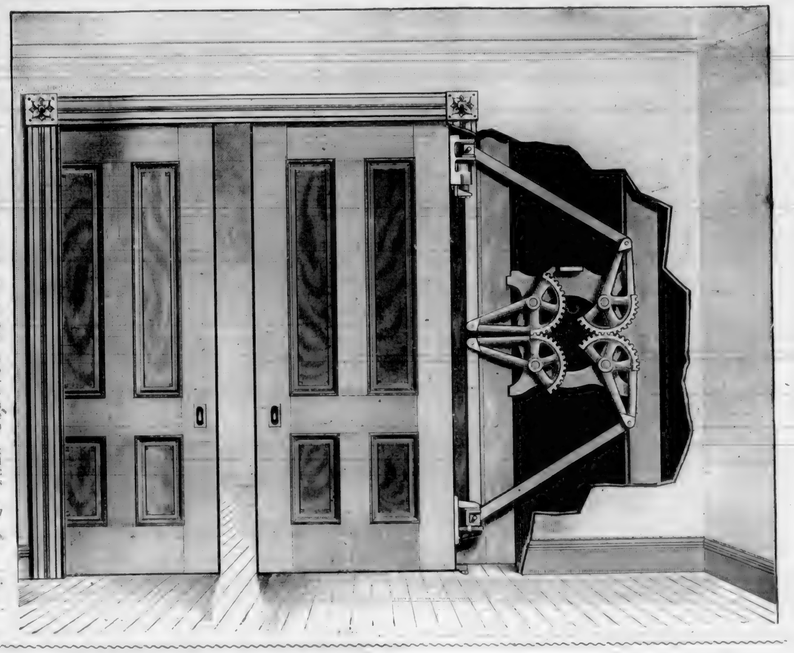
DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

See a full size working model at our store.



WE SELL
The Yale & Towne Mnfg Co.
CELEBRATED
YALE LOCKS.

W. & P. **SHINGLE STAINS**

In soft and pleasing tints.
Of highest grades of material.

BUILDING NEWS.

SANTA ANA

Messrs. Bristol & Rawley have leased the corner of Main and Fourth streets for twenty years and intend to erect a two story brick building. It will front 80 feet on Main by 65 feet on Fourth.

City engineer Kellogg has asked for a two weeks extension of time to prepare his report with plans and specifications of the sewer lines through the city at the expiration of which they will be ready for bids.

SANTA BARBARA

A new sugar beet factory to be located near Santa Maria, Santa Barbara County, at a cost of $135,000, is in contemplation.

SANTA ROSA

Simpson and Roberts will begin the erection of an addition to the Miller & Hotchkiss winery at Winsor. The new building will be 80x130 feet. It is the intention of Messrs. Miller & Hotchkiss to increase the capacity of their winery at least two hundred thousand gallons. The new cooperage will be in place in time to receive this year's wine. An addition is being built to the Fulton winery and its capacity will be materially increased. A handsome new cottage is being erected on the site of the one recently destroyed by fire on the Briggs estate property at Fulton.

STOCKTON

Contracts have been awarded for the erection of an eight room brick school building for Fair Oaks District. Chas. Beasley & Son, Architects. Lee & Lewis do the carpenters work and Robbins & Hanks the brickmasons work, the cost aggregating $15,300.

Thos. I. Levy has awarded the contract for building a cottage on California & Lindsay streets to Robt. Powell for $1117.—Geo. Rushforth was the architect.

TRACY

Bids for the re-building of the Odd Fellows Building were opened on the 21st of September and the contract for carpenters work, plumbing, ironwork and plastering was awarded to Fk. Woodruff of Stockton and the brickwork to Confer Shannon and Tucker of Stockton their bids aggregating $8080. The Odd Fellows to furnish all brick, cement, lime and sand which will run the cost of building to about $8500. Geo. Rushforth of Stockton is the architect and the building will be pushed to completion under his supervision.

AUBURN

Building is picking up, work is about to start in a $800 school house, Rock Creek School District. A five room cottage for John Davis. Foundation just completed for a $4500 School House at Dutch Flat, J. C. Woodward, contractor. M. T. Barnette is building a small cottage.

Patent Screwless Door Knob.

Plans and Specifications Invited for an Hospital Building.

Public notice is hereby given to architects that competitive plans and specifications for the erection of an hospital building will be received by the Board of Supervisors on MONDAY AFTERNOON, September 12, 1898.

The proposed building to be of modern design and to be constructed of stone or brick, or of both, with all the latest scientific improvements.

The said hospital building to be erected on the lot of land commencing at the most southeasterly corner of a tract of land known as and designated, on the official map of the city and county of San Francisco, as the "Almshouse tract."

The said plans and specifications to be so prepared that the cost of the building shall not exceed in the aggregate the sum of three hundred thousand ($300,000) dollars.

The architect whose plans are adopted will be appointed architect and superintendent of the building, and will be required to give a good and satisfactory bond to insure the completion and construction of the said building for the amount of the cost as made by the said architect. The architects submitting plans determined by the Board to be second, third and fourth in merit will receive premiums of $1000, $750 and $500 respectively, with the understanding that any features of said plans and specifications which may be considered useful or necessary to be embodied in he plans adopted may be used without urther cost of charge.

JNO. A. RUSSELL, Clerk.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

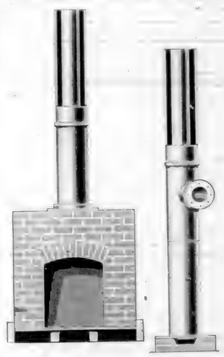
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET, SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See **CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.**

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

For Sale by CHARLES J. WATERHOUSE, 421 Market Street, San Francisco.

To our Customers and Friends on the Pacific Coast.

Through frequent complaints made to us, we have learned that unprincipled and dishonest dealers on the Pacific Coast have counterfeited our trademark numbers and substituted inferior, spurious goods as ours, when ours were distinctly ordered, thus defrauding their customers and injuring our trade and reputation.

Our goods are acknowledged to be the best, and are fully warranted by us, and are marked with our name or initials or with our well-known trademark and catalogue numbers.

We request direct notice if any goods alleged to come from us, or bearing our trademark or numbers, prove to be other than the best, and perfect in every respect, as we will follow up and expose such frauds for our customers' and our own protection. We have no exclusive agents on the Coast, but our goods are obtainable from all respectable dealers in drawing materials, stationery, hardware, artists' material, etc.

RESPECTFULLY,

Sutter near Scott. Carpentry, etc; o, Mt. Zion Hospital Ass'n; a, W. J. Lyon; c, M. J. Field; signed, Sept. 27; Filed, Oct. 4; cost $5550. Excavations, brick work, etc; c, Martin Fennel & Son; cost $804. Sewers, etc; c, Schanz & Grundy; cost $1390. Painting, etc; c, D. Zellinsky; cost $500. Electrical work; c, J. H Wolf; cost $282.50.

Texas near Yolo. To build; o, John P. and Julia Sauer; c, Gustave Rasmussen; cost $600.

Third near Market. Plumbing; o, Ed. Rolkin; a, Percy & Hamilton; c, Ickelheimer Bros; signed, Oct. 13; filed, Oct. 14; cost $1495.

Twelfth Ave. near P St. Cottage; o, Wm. H. and Mary Roch; c, R. Reechenback; signed, Sept. 4; filed, Oct. 1; cost $2000.

Seventy-second and Florida. To build six flats; o, Thomas Pennington; c, Wm. Helbing; signed and filed, Oct. 12; cost $5570.

Twenty-second near Howard. Barn; o, Jas. Burke; c, day's work; cost $1000.

Van Ness and Clay. Steam heating, etc; o, St. Luke's Church; a, A. Sutton; c, W. W. Montague & Co; signed, Oct. 11; filed, Oct. 12; cost $1941.

Washington near Scott. To build; o, E. B. Cutter a, Edgar A. Mathews; c, Edward Leiter; signed, Sept. 22; filed, Sept. 26; cost $7342.

ALAMEDA

Walnut near San Jose Ave. Alterations and additions; o, Mrs. Gardner; a, Charles Shaner; c, C. S. Brown; signed, Sept. 26; filed, Sept. 27; cost $1460.

BERKELEY

Bancroft Way near Bowditch. Ten-room house; o, Annie B. Voorhies; a, A. W. Smith; c, Stockholm & Anderson; signed, Oct 6; filed, Oct. 7; cost $2847.50.

FRUITVALE

Fruitvale Ave. and Telhaut. Heating, etc; o, Trustees of Fruitvale School; a, D. F. Oliver; c, J. S. Burpee; signed, Sept. 23; filed, Sept. 24; cost $8279.

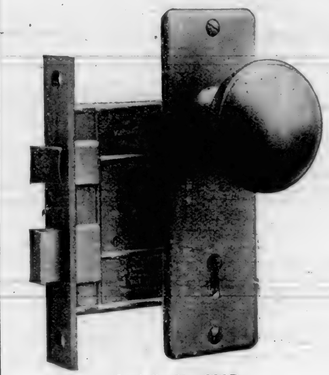
The "Vulcan" Locks

All Wrought Metal—with "Compensating" Hubs.



Lock Set No. 220B.
One-half Actual Size.

Our General Offices in New York have recently received the following unsolicited letter from a prominent builder and contractor. Believing that the statement of experience it contains will be of interest, we reproduce it below.

An Artistic Brochure on Vulcan Locks, also a Catalogue of 90 pages, will be sent on request.

The Yale & Towne Mfg. Co.

LOCAL OFFICE:
Mills Building, San Francisco.

GENERAL OFFICES: 9-11-13 Murray St., NEW YORK.
WORKS: Stamford and Branford, Conn.

OFFICE OF A. BEINHAUER,
124 Maiden Lane,

NEW YORK, July 11th, 1898.

The Yale & Towne Mfg. Company,
9-11-13 Murray Street, New York.

Gentlemen:-Having lately had occasion to use and apply your "Vulcan Locks" in the Anderson Building, 12-14-16 John Street, I take pleasure in mentioning the fact that in the application of these locks there is a large saving of labor as compared to the ordinary CAST-case locks.

The difference, as I found it, was that while a man put on six to eight of the latter, he could in the same space of time put on twelve to fourteen "Vulcan Locks," thus decreasing the cost of labor to a considerable extent.

Another feature about these "Vulcan Locks" is that while they give as good service as any cast-case lock of their denomination, they do not require as much cutting away of wood in the lock-rail, thereby strengthening the door to an appreciable extent.

Wishing you all success with your "Vulcan Locks," I remain

Yours truly,

(Signed) ALFRED BEINHAUER.

VOLUME XIX. OCTOBER 20th, 1898. NUMBER 10.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

IN OUR issue of the 20th of last month, we called attention to the difference between the Constitution of the State, and as it had been constructed by the Supreme Court of our State, with reference to Mechanic's Liens, and the amount for which they can be enforced, the Constitution saying that the lien should extend to the full value of the labor performed and materials furnished, while the Supreme Court have added the proviso that such amount shall not exceed as to the owner the contract price.

We stated in that issue that we would, in this, call attention to the manner in which the Constitutional provision referred to had also been departed from in practice as to the speedy and efficient enforsement of the lien. The Constitution not only intended by its provision that a man should have a lien for the full value of of his labor and his materials, but that he should also have a speedy and efficient enforcement of it. It meant that he should have an "efficient" remedy, so that his claim would not be exhausted by the expenses of collection, nor impossible of collection by being weighed at every step with impeding technicalities calculated to defeat him. And yet, it is a common thing to hear some of our Superior Judges from the bench state openly that they do not like Mechanic's Liens, and will, at every opportunity, interpose any technicality for the purpose of defeating them. Every technicality open to the conception of the human mind has been resorted to by the trial courts, for the purpose of defeating them, these Courts forgetting that they are called upon to give a most liberal construction in favor of the Mechanic's lien by reason of the fact that the right to it is a Constitutional right and that Constitutional rights are always to be looked upon with favor, instead of with disfavor.

Now, as to the speedy enforcement of the lien. After providing that the lien should be for the value of the labor done and material furnished, the Constitution says:—"the Legislature shall provide by law for the speedy and efficient en-

forcement of such liens." The Constitution intended that there should be no "laws delays" in reference to the enforcement of such liens. In practice, however, since the adoption of the Constitution, mechanic's lien cases are about the hardest to enforce, so far as delays are concerned. A number of cases are commenced against the same party. They are finally set for trial. Then a move is made by the defendant to consolidate all of the cases. The consolidation takes place, and the cases, as consolidated, are continued from time to time, it being difficult to get all of the parties ready at the same time. Then, finally, they are tried, an appeal is taken, and another delay takes place. Neither in the Superior Court nor in the Supreme Court have the cases been set down immediately for trial; but they have had to take their places on the calendars in regular order with other cases, the Constitutional provision that they shall be speedily tried, evidently being overlooked by the Courts.

In marked contrast to this practice in reference to the foreclosure of Mechanic's Liens is the disposition made of an action for unlawful detainer. There is no provision of the Constitution as in the case of a Mechanic's Lien requiring the speedy disposition of an action of unlawful detainer, and yet the Court without any such provision, sets down for trial such actions in advance of other cases and speedily disposes of them. A laborer who has a lien against property is delayed in the enforcement of his lien, and cannot get his money secured by it for the purpose of paying his rent. The landlord, not getting his rent, brings an action of unlawful detainer. The case is at once disposed of, and the laborer is evicted for non-payment of the rent. The wealthy landlord who has no constitutional provision behind him, giving him a speedy remedy, and who is able to wait for his money, commences his action and evicts the laborer and his family, while the laborer, with the constitutional provision behind *him* for the speedy enforcement of his lien, is unable to get his money through its foreclosure, with which to pay his rent. This is an anomalous state of affairs.

THE BEGINNING OF A NEW EPOCH.

THE YEAR 1898 will always be distinguished as the one of all others marking the extremest limit of depression reached by the building trades in California. No great structures were either begun or ended in that year and the number of smaller buildings erected was less in proportion to the population then ever before known. The war, drought, the Klondyke all had their depressing influences but more than all other reasons combined, the drought, which decreased the general income of the State not less than $50,000,000, and universally contracted individual resources in every direction, is directly responsible. It was a catastrophe that no business sagacity or foresight could prevent and coming after years of liquidation and low prices was an additional burden and hard to bear. It is not to be wondered therefore that architects, builders, mechanics and all kindred trades should have suffered from a a period of depression quite unique in the history of the State.

It is believed, however, by men whose judgment is entitled to great consideration, that the extreme limit of business depression has passed and that future indications are unmistakably encouraging. Besides the abundant supplies of money and decreasing rates of interest, real estate has reached a point where any change involves an increase of values. Under these conditions building interests cannot but be stimulated. The period has also arrived when a general movement is to be made in altering the old fashioned office buildings into structures that will attract tenants. The great modern structures like those erected in the last three years are absorbing all the desirable renters. Without transformation there will be no income from these old and desirably located buildings and at the first sign of inprovement in business a general renovation will be in order. It is a highly encouraging indication also that most of the local architects are busy in the preparation of plans for proposed buildings to an unusual extent for this season of the year.

But it is not from these internal or local signs of improvement that lead sagacious men to believe in better times in the near future, it is thought that a great movement has begun towards this coast that will have a wonderful effect upon the future of this city and inaugurate a period of advancement such as San Francisco has never known before.

As soon as the government decides upon a definite policy for the Philippines hundreds of companies that are ready to undertake their development will be found and naturally their head-quarters will be in San Francisco. An era has begun in China that will open that populous country to new enterprises. Russia-Siberia, will soon begin to contribute to this city's trade. All these projects mean increased commerce and new lines of steamers to this port. The result cannot but be stimulating to the last degree. With this new epoch, about to begin, San Francisco cannot but expand in a remarkable degree.

DEPOPULATION OF SAN FRANCISCO.

IT IS estimated by a very reputable authority that the population of San Francisco is now, not in excess of 320,000. In 1890 the census gives the number at 298,977 and if the above estimate is correct the increase for eight years is only 21,000, or considerably less than one per cent per annum, and very much below the average natural increase. While these results may be disputed it is admitted by the most sanguine that neither in commerce or population is San Francisco holding its own. This stagnation appears to be local. The Sound ports, Portland and Los Angeles are each making wonderful strides in advance while Denver has not only recovered from its exploded boom but is building with greater rapidity than ever. Even the small cities over the bay as well as upon the peninsula are making rapid and permanent progress, filling up with people who by preference would live in a city if conditions permitted.

Only San Francisco, notwithstanding its incomparable position as a maritime and commercial metropolis, gives indications of actual retrogression. Never before has the number of vacant tenements and business blocks been so great.

The Klondike exodus or the drought does not explain the general flatness of the building trades or why with the abundant supplies and low interest rates of money and with real estate lower than for many years, a reasonable degree of activity should not prevail. The difficulty is believed to be internal altogether and a natural result following the subordination of business to politics. Taxes, out of all proportion to the benefits accruing, confront the manufacturer and drives him to other locations where the cost of living is less and business not taxed out of existence. The custom also which prevails in San Francisco, with a virulence surpassed no where else, of "nagging" corporations prevents new enterprises and drives capital away. So with the family. It is believed that San Francisco loses hundreds yearly who will not trust the lives and education of their children in schools which common report says are insanitary, overcrowded and out of repair, managed and controlled by a board of directors which is incompetent, venal and corrupt. The numbers who are driven from San Francisco to neighboring cities is too great to be regarded with indifferance. There are other reasons for this wholesale abandonment of San Francisco. When the painful facts are realized perhaps some method of relief may be discovered.

EXTENDING THE FIRE LIMITS.

IT IS said that a movement has already begun, under the auspices of the Board of Underwriters with the active cooperation of the authorities, for a considerable extension of the present restricted fire limits. How soon the change will be made, is not known, it is intimated that it will be gradual, but, it is believed that the practical inclusion of the entire city, excepting possibly the extreme borders, will be accomplished within five years.

That the movement will be opposed by that class of property owners who are indifferent to the general welfare of the city is to be expected. That a change in the fire limits so as to include all those large business sections of the Mission and Western Additions which are now beyond the present boundaries will be welcomed gladly by a large majority of the investing class is already assured. Official notice of an impending change of such great importance ought to be given as early as practicable.

THE HEARST INTERNATIONAL COMPETITION.

THE GREAT international contest of architects to decide the successful competitors for the honor of furnishing plans for the new buildings of the University of California, reached a conclusion at Antwerp on the 4th inst. Over a hundred different plans were submitted, some of them from the most accomplished architects in the world. Foreign architects were greatly interested in the contest and the competition seems to have excited much attention all over the continent of Europe.

Of the one hundred plans submitted, eleven received the unanimous commendation of the committee of experts chosen to decide which were the most worthy. This committee consisted of Norman Shaw, R. A., London; M. Pascal, Paris; Professor Wallot, Dresden; Walter Cook, New York and J. B. Reinstein, San Francisco.

The names of those whose preliminary sketches entitle them to enter for the final competition are as follows:—

Barbaud & Bauhain of Paris; E. Benard, Paris; F. Blunschli, Zurich; D. Dexpradelles & Stephen Codman, Boston; Rudolf Dick, Vienna; J. S. Freedlander, New York; Heraud & Eichmuller, Paris; Howard & Cauldwell, New York; Howells, Stokes & Hornbostel, New York; Whitney Warren, New York.

The reward gained by each successful competitor, besides the distinction of success in such a noted contest, is in cash $1200, and the privilege of entering into the final competition. In addition to this reward, an allowance will be made to those who desire to study the environments of the University, to defray traveling expenses to and from San Francisco. Six months are to be allowed in which to mature the preliminary sketches for the final competition. All the completed plans are then to be placed upon exhibition in this city.

Norman Shaw, the English expert is reported to be enthusiastic over the results of the competition though his predictions as to the ultimate cost of carrying out the plans is ominous of their final acceptance. He is quoted as saying that $100,000,000 would probably be required to complete the plans, though $20,000,000 was the sum suggested as the limit cost of constructing the University buildings.

The adoption of a harmonious plan at this time would not necessitate, of course, immediate construction, but nothing would justify saddling the future with an obligation which events and conditions might prove to be entirely impracticable—especially as at this time the University of California is but an immature child and far removed from full growth. Columbia College of New York, though the wealthiest college in the world, will expend but $7,500,000 on its buildings and the Leland Stanford, Jr., University with an endowment of $20,000,000, finds that $3,000,000 invested in college structures, is entirely adequate to its needs, why then, it is asked, should California contemplate the expenditure of such an enormous sum as proposed or adopt plans for future expenditure of such dimensions? If the purpose is to out do the whole world in lavishness in providing university buildings that result might be attained but at a cost of self respect. It would neither be prudent or sagacious.

It is for this reason that a lack of practical results is feared from the great international competition and explains why California architects hesitated before embarking in an enterprise that from the nature of things, of which they were fully informed, was liable to result in no practical conclusion. The limited time allowed to formulate sketches, might have also had some influence, six months is a very brief period in which to conceive in detail a colossal group of twenty-eight large structures even for architects most fertile in ideas and rapid in execution. The time allowed appears much too contracted too plan that which may take half a century to construct.

As to the style of the selected plans it is known that, generally, they are of French school, certainly the most

admirable in the world, a school that has supplied California with some of its most eminent architects, yet to many it would be disappointing to learn that that the Regents of the University of California should adopt any school so distinctly national as the French as the style in which these buildings are to be erected.

In the opinion of some thoughtful men, there are signs of the development of a new school of architecture, composite it may be, but sufficiently distinctive for our own clime and appropriate to our national life. So splendid an example of college architecture as the university buildings are expected to be will afford an opportunity for the introduction of new ideas embodying in it the traditions, hopes and ambitions of the most lavishly endowed of all the states.

ENGINEERS FOR FIRE PROTECTION.

ONE of the demands of the municipality is that all new buildings and old shall be protected against fire and that any installations contained therein shall be free from any immediate possibility of fire. Modern buildings of large size are equipped with steam and electric light machinery, fire from which could arise at any moment unless precautions are taken of a most definite character to prevent the same. In consequence of this a department of engineering new in its way has been suggested by Mr. H. L. Phillips, which will consider ways and means of protecting property from fire in any form due to the arrangement of machinery within This is a most interesting field of investigation and worthy of serious consideration by not only professional men or engineers, but the public at large, to whom the loss by fire annually exceeds one hundred millions of dollars.

The electrician should feel particularly impressed with the necessity of putting in an installation safe in every respect and amply protected with the proper fuses and adjustment of wires from fire risk. Whenever there is a mystery attached to a fire, allusion is made to the electric light wires in the building; but in answer to this we may say that under no circumstances is a building under less risk from fire than when wired by a conscientious contractor in a manner that meets with all the requirements of the city fire underwriters.

Attention need not be especially directed towards the purely electrical portion of the work, but to the steampipe system, boiler, position of coal supply, etc. The general arrangement of these things counts for a great deal in the eyes of insurance companies when application for insurance is made by a large concern. A casual examination of the interior of a building does not always disclose the immediate chances of fire present there. Such an examination should be backed by considerable experience and an extensive knowledge of the effects of too close a juxtaposition to materials normally safe, but which under the influence of a constant heat, vibration, etc., might change in character and give rise to a conflagration.

As the hygienic demands of city residences became more pronounced and it was necessary to discover and prevent the mischief arising from poor sanitary accommodations, a new field of engineering developed and received recognition in many of the largest universities under the name of "Sanitary Engineering." In the same sense the necessity for a department of fire-protection engineering in some of the universities is obvious. A degree of this kind would confer upon its holder an immense amount of responsibility in the inspection of buildings and demand from him an intimate knowledge of many of the details of construction in electrical and mechanical engineering.

Mr. Phillips makes mention of the fact that "the electrical engineer must give consideration to the element of fire in arranging the lighting or power apparatus, and special rules have already been formulated regarding the installation of such an equipment. All matters of this sort, strictly speaking, come within the scope of fire-protection engineering and should be taken up in connection with it. And here we have another field for men trained in the new science."—*The Electrical Age.*

CORRESPONDENCE

To the Editor of the California Architect and Building News.

DEAR SIR:—Your remarks in your last number as to the interpretation of the Constitution of California by the Supreme Court in regard to Mechanics' Lien Law were very timely and *apropos.*

Taking your quotation of the Constitution as correct, there cannot be any doubt whatever to any man with a mind and who understands the English language, as to the meaning and the intention of said clause. There is only one meaning to this which is self-evident—"Mechanics, material men, artisans and laborers of every class, shall have a lien upon which they have bestowed labor or furnished material for the value of such labor done or material furnished."

There is a moral to all this, and that is, the utter futility of putting the interpretation of Fundamental Law into the hands of men brought up to the practice of law. Six honest unprejudiced men picked up at hazard with a knowledge of the meaning of words, are more to be trusted, experience shows than the greatest jurists, whose education has been the twisting of language from its legitimate meaning.

It would be well in the matter of statute law, to have all bills introduced in the legislature passed upon at once by the Supreme Court, or other more reliable authority—before they became law; this will eliminate all that uncertainty which now prevails as to judicial decisions, continuing until the matter in dispute has gone through all the expensive process of proceedure in the lower courts and final appeal to the Supreme Court—a needless waste of both time and money.

If the proposed amendment to the Constitution passes, allowing an interval between the introduction of bills in the legislature and their consideration, that interval could be used by the Supreme Court or other more reliable authority in finding out and reporting whether these bill are constitutional or not; so that no more time might be wasted on those which are declared unconstitutional.

STROLLER.

ASBESTOS CEMENT FOR FIRE-PROOFING.

AMONGST the various products for fire-proofing, the Asbestos Cement Kuhlewein, invented by Engineer A. Kuhlewein in Berlin, has attracted great attention. This asbestos cement has a fine color (about that of slate), is absolutely fire-proof and smoke-proof, and remains unchanged when exposed to heat or cold, as well as when exposed to any atmospheric conditions and changes, including that of temperature. The cement is capable of being nailed, planed, sawed or cut. It is of very light weight. It also deadens the sound, which latter capacity is by no means unimportant. It can be polished, painted or papered. The highest ministerial building and fire departments have examined and tried this product, and have recommended the use of the same.

At the great official fire trials which took place at Berlin on 9th and 11th February, 1895, where the asbestos cement doors were exposed to the hightest temperature then established of 1200 to 1300 degrees C, and withstood the same, from both sides, without showing any change in shape or material, the asbestos cement Kuhlewein was accorded the diploma on account of its excellence.

Further trials were made in the year 1895 with this cement at Altona, in the yard of the fire department. For this purpose a small house had been built with it in the shape of walls, ceilings, floors, doors, columns, and also as protecting-covers of supports. The trial was extended six hours. All the different parts withstood the heat perfectly, the building was entirely sound and not damaged after the fire.

In Hamburg the same was tried in the gas house by the city authorities on the 30th of September and 18th of October. For these trials shells of asbestos cement about 4 centimeters thick were furnished, which can be put around columns and taken off again; the temperature was 1300 to 1400 degrees D. These shells protected the pillars 4 hours and 35 minutes.

This cement is used for various building purposes, and being absolutely fire and smoke-proof, as well as indifferent to the highest and lowest temperatures, also having the capacity of deadening the sound, being impervious to the influence of weather, its light weight and its adaptability to all kinds of building constructions, renders it one of the most valuable building materials.

Coverings in th ckness of 1½ centimeters, and for walls or doors, etc., of 2 to 3½ centimeters, render the same fire-proof, even in case of prolonged fire. It is to be remembered that a fire-proof material should not only not burn, but it must not be injured by either fire or smoke, nor lose its strength. Asbestos Cement Kuhlewein, is acknowledged the most perfect protection against fire in the form of coverings of iron constructions, as pillars and supports, for fire-proof doors, inferior walls, ceilings, fire-walls, stair-case coverings, cases and safes for documents, money, etc. Further, a protection against heat and cold, and all heating apparatus and hot-air conduits. Also a protection against noise, as for instance in buildings where gas motors are working. How indifferent and protecting against heat and cold was proved in Berlin in the former Gambrinus (now Rudesheimer) cellars, where the hot air conduist pass through the ice cellars without decreasing the heat in the hot-air conduits, nor affecting the ice in the cellars in the least degree.

The deadening of sound was proved by the covering of the motors and covering of the cellar walls and ceiling in the National Hotel, Berlin. The success was perfect, since the noise from the cellar could not be heard in the other parts of the hotel after this was done.

For the shipbuilding industry, the covering of all walls and ceilings would render it impossible that the wood fixings could be affected by fire rising on shipboard.

Doors made of Asbestos Cement Kuhlewein are far preferable to iron doors, in so far as they are fire and smoke-proof, and they do not become hot, and thus the men of the fire department can, at all times, closely approach the same. Furthermore these doors can be more easily demolished in case of necessity to get at the location of the fire. These doors have found their introduction in many of the barracks, manufacturies, mills, warehouses, stables, and they are made in the most simple and most elegant shapes, so that the same can readily be used in dwellings, theatres, museums, etc., etc.

It is brought to commerce in slabs, or other shapes, in thickness of 1½ centimeters and upwards, on zinc wire netting, but also more extensively in the shape of cement powder. In the latter case it is worked as a paste, like all lime, cement and gypsum, upon the zinc wire netting, and can thus be worked by any laborer.

In order to prove the absolute fire-proofness of asbestos cement, the following trial with a safe was made at Aix La Chapelle. The filling of this safe consisted of asbestos cement only. The trial took place on the 15th of April, 1893, in the large furnaces of a local firm, and a number of engineers and experts were present. The safe was filled in the presence of these gentlemen. With papers and printed matter, such as we were handed over by some of the gentlemen present. The safe was closed and put into the furnace.

The heat in the furnace was so great that the safe had reached whiteheat after fifteen minutes. After another fifteen minutes the iron of the safe commenced to burn, emitting sprays of sparks. Then the safe was taken from the furnace, was immediately fastened to a crane and elevated as high as the crane would permit, and then dropped. The temperature of the hot safe was then decreased by applying cold water, and the safe was then opened. The door worked as easily as prior to this trial, and to the greatest astonishment of all the witnesses present the contents were well preserved and undamaged. The experts were unanimous in the opinion that the result of this test, carried to an extreme, was an excellent one and nobody of those present had believed prior to the opening of the safe that of the contents there would be anything found but ashes. The experts signed every one of the papers contained in the safe with their names and the safe itself was stamped with the stamp of the Steam Boiler Revision Association of Aix La Chapelle. The heat required for rendering wrought iron malleable is 1300 to 1400 degrees C; the burning of wrought iron takes place at 1500 to 1600 degrees C. These are, therefore, temperatures to which heretofore safes have not been exposed at any trials, nor at any conflagrations.

The Institute for Testing of Building Materials at Charlottenburg, certify that samples of this asbestos cement of an age of 28 days were exposed to a water pressure of 2 to 2½ atmospheres during three days, and no water percolated the slabs.

The chief of the fire department of Bremen, Germany, Mr. Ditmann, certified under date of September 18th, 1897, that of all materials known at the present time which served as

protection against the effects of fire, or for the fire-proof covering of iron or steel, the Asbestos Cement Kuhlewein is the best, and by far the most effective.

PROPOSED NEW CONSTITUTION FOR THE A. I. A.

THE following draft of a Revised Constitution has been unanimously adopted and recommended as a substitute for the present Constitution by the committee appointed by the President by virtue of a vote passed at the Thirty-first Annual Convention, at Detroit, September 30, 1897, and is now to be submitted for letter-ballot. The amendments to the by-laws will be brought before the convention to be held in Washington, November 1, 2, 3, 1898, for action, an outline of which, prepared by the committee is appended hereto.

ALFRED STONE, *Secretary*.

CONSTITUTION.

ARTICLE I. — NAME.

The corporate name of this Organization shall be, "The American Institute of Architects."

ARTICLE II.—OBJECTS.

SECTION 1. The objects of this Institute are: To organize and unite in fellowship the architects of the United States of America, and to combine their efforts so as to promote the artistic, scientific and practical efficiency of the profession.

ARTICLE III.—MEMBERSHIP.

SECTION 1. The membership of the Institute shall consist of Fellows, Associates, Corresponding and Honorary members.

SEC. 2. The condition of membership shall be honorable service in the field of one of the above classes of membership, as defined in the By-Laws.

SEC. 3. The title of Fellow shall be granted for professional merit only.

ARTICLE IV.—OFFICERS.

The Officers of the Institute shall be a President, First and Second Vice-Presidents, and a Secretary, who shall also be Treasurer; all of whome shall be Fellows. There shall be a Board of Directors consisting of the four above-named officers, *ex officio*, and such additional Fellows as shall be prescribed by the By-Laws.

ARTICLE V.—ORGANIZATION.

This Institute is an association maintaining local organizations of its members known as Chapters, incorporated under the laws of the several States wherein they are established.

ARTICLE VI.—CHAPTERS.

The President and Secretary of each Chapter shall be fellows or Associates of the Institute.

Each Chapter shall hold an annual meeting and present an annual report to the Institute.

ARTICLE VII.—GOVERNMENT.

SECTION 1. The Government of the Institute shall be by Delegates from the Chapters in convention assembled, its Officers and Board of Directors.

SEC. 2. The Board of Directors may by a formal vote delegate its powers in whole or in part to an Executive Committee chosen from its membership, stating the powers granted and a limit of time for their exercise.

SEC. 3. The Board of Directors shall annually elect a Judiciary Committee from its own membership and establish rules for its guidance. This Committee shall hear and adjudge all complaints of members against members, and its findings shall be conclusive upon all questions of fact involved in the evidence submitted. Appeal in writing may be made to the Board of Directors upon questions of professional or ethical policy. If satisfied of the existance of newly discovered evidence material to the issue, the Board may, in its discretion recommit the case to the Committee for a rehearing upon the facts; but, save as to the existence of newly discovered evidence, the Board shall have no evidence except such as may be reported to it by the Committee.

ARTICLE VIII.—MEETINGS.

The Institute shall hold an Annual Convention and such other meetings as are provided for in the By-Laws.

ARTICLE IX.—DEFINITION.

The term "State" throughout this Constitution and the By-Laws shall also apply to the District of Columbia and Territories.

ARTICLE X.—AMENDMENTS.

This Constitution may be added to, altered, or amended, on the written proposition of ten or more Fellows by a three-fourths vote of the delegates voting at an Annual Convention; probided three months previous notice of the proposed change shall have been sent by the Secretary to each member of the Institute and to the Secretaries of the several Chapters.

LESSON FROM FIRE AND PANIC.

ORE important than these details of construction is the question of arrangement of buildings with the view of preventing loss of life from fire. Warned by frequent disasters, the legislature has from time to time made provision for protecting persons from sudden fire and panic, and for insuring to the inmates of certain buildings reasonable means of escape.

Examination of this kind must be thorough, for it is difficult to exhaust the possibility of mischief caused by careless workmen in old or in modern times. I have found in an old house the brickwork of a chimney breast cut away to enlarge a cupboard, a thin board being substituted, which had vidently done duty for years in that position.

And with regard to any building, the architect cannot be too cautious against assuming that reasonable care will be taken in managing it. Most houses are at times, often for a very long time, left in the hands of people without sense of responsibility. That is an additional reason for making every structural provision against the chance of a fire. The fate of Cowdray House, in Sussex, though the story is a hundred years old, contains nothing that might not now be paralleled.

The mansion, which was one of the grandest in the country, was being repaired and decorated in preparation for the owner's wedding, and it was left in the hands of caretakers and workmen. All the more valuable of its contents were temporarily stored in a gallery, and a room close to this place was selected for the carpenter's shop, the fires being closely surrounded with shavings. During the night on which all was finished, fire was observed in the workshop.

The neighbors assembled. The moat was full of water,

but nobody could find the key of the engine-house. The destruction was practically complete.

The London Building Act, 1894, provides, by Section 61, that every building over 30 feet in height used wholly or in part as a dwelling house or factory, *and having a parapet*, shall have a dormer window or door opening on to the roof, or a trap door with a fixed or hinged stepladder leading to the roof, or with other proper means of escape. If there happens to be no parapet there is no such provision. I venture to think that it would only be ordinary prudence to make this provision in any house or factory where there is reasonable doubt as to the means of escape by the ordinary route. Section 62 partially meets this view by requiring that any storey in the roof, the floor of which is over 60 feet above the street, shall be constructed of fire-resisting materials; and Section 63 provides that every building over 60 feet high shall have on the storeys, where the floors are over 60 feet above the street, "such means of escape in the case of fire for the persons dwelling or employed therein as can be reasonably required in the circumstances of each case." No such storeys can be occupied until the London County Council certifies that this has been done. This is new legislation, and it has now become a very important part of the duty of the Council to say what can be reasonably required in such cases.

The height of 60 feet is fixed because that is the greatest height to which a movable fire-escape will reach, and without some special provision the only means of escape from these high stories would be by descending, if that were possible, to the lower stories, and increasing the number of persons there in peril. Schemes to be applied to lofty hotels and houses more or less crowded at night have come before me in great variety, many of these very inadequate. It seems clear that the law, which leaves the occupiers of floors up to 60 feet in height to take their chance, intends that those on higher floors shall escape. They may have a gallery or an iron ladder or staircase for access to the roof of an adjoining building, or a series of ladders may be contrived that will conduct them clear of the windows of the burning building down to the ground. But 60 feet is a great height from which to expect women, children and sick persons, scantily dressed, suddenly alarmed in the night, and for the first time in their lives, to descend by an external ladder, in any weather, and probably in the dark. We may realize the condition in which people escape, from the account of a fire that happened at the Scottish mansion of the Duke of Argyll, in which praise was given to the Princess Louise for her presence of mind in running back from the garden to get stockings for the rest of the household who had rushed out barefooted. For people in that condition steep ladders with ordinary rounds are useless. They must be of tolerably good slope, have flat treads and hand rails and there must be suitable protection where necessary against falling into areas or through skylights. The escape door must have such fastenings only as can be easily opened from within. It must be easily found by night, and the bottom of the escape must be in some open space quite clear of danger. But whether the escape delivers to the ground or on to some willing neighbor's roof, there is risk that it will be made use of by burglars and by inmates of both premises for improper purposes.

If a separate staircase leading down to a separate door of exit is provided in the building, it will very likely be allowed to go out of use, and will be turned into a store place for lumber. On the other hand, if the construction of dwelling rooms above the 60 feet limit is of very great consequence, the owner may reasonably be required to make and keep up such arrangements, however costly, as will be really efficient.

By the 74th Section of the London Building Act, when a building over 1,000 feet in area is used in part for purpose of trade and manufacture and in part as a dwelling house, the two parts must be separated by walls and floors of fire-resisting materials, and all means of approach to the dwelling house portion must be constructed throughout of fire-resisting material. But the walls of staircases and passages may have openings fitted with fire-resisting doors to communicate between the two portions, for which purpose hard wood two inches thick is reckoned fire-resisting. For staircases hard wood two inches thick is also permitted, and good concrete when filled in between the joists of floors is fire-resisting.

It will be observed that the term "fire-resisting" is used and not "fire-proof." The construction must not add fuel to the fire, but resist it for at least a considerable time, during which the inmates of a building may escape and fire appliances be brought to bear. If the contents of the room or even of the building cannot be saved, so much the worse for the owner or the insurance company; but the fire should rarely extend to the adjoining apartment on either side or to a storey above or below, and the smoke should be kept from staircases and passages. This means giving to adjoining sections of a house as nearly as practicable the same protection against each other as a good party-wall affords to the inhabitants by an adjoining house.

To be continued.

BOOKS AND PERIODICALS.

BUILDING CONSTRUCTION AND SUPERINTENDENCE by F. E. Kidder, Fellow A. I. A., is a work highly esteemed by architects and invaluable to the builder. Part II devoted to Carpenter work has just been issued and is fully equal in practical value to Part I which treated of masonry and its details. Numerous engravings adorn the work.

The complete novel in the November issue of LIPPINCOTT'S, "A Triple Entanglement," by Mrs. Burton Harrison, has its scenes mainly in Spain and England. The hero is an American, whose course of true love does not by any means run smooth, but leads him into a safe harbor at last. The tale is one of this favorite author's best, and perhaps the longest which has ever appeared in LIPPINCOTT'S the rest of the short stories are more than interesting.

STOCKHOLDERS' MEETING.

AT a meeting of the Stockholders of the Western Expaned Metal Fireproofing Company held at their offices in the Claus Spreckels Building, October 6, 1898. The following officers and directors were re-elected for the ensuing year:—D. E. Garrison, Jr., President; Chas. F. Runyon, Vice-president; S. W. Backus, Secretary; Nathan L. Bell, Manager; Chas. F. Kinsman.

PURE WATER IN CITIES.

WATER from wells dug within the limits of a city is always to be looked upon with suspicion, even when its smell is sweet and its taste good.

Those who have had experience in such matters can vouch for the fact that such dug wells may become the receptacles of all sorts of foreign bodies, while neither the taste nor the smell of the water, may be affected. Binghamton, N. Y., has recently furnished a case in point. One of its citizens had a dug well of some fifty feet deep, the purity of whose water was noised abroad all over the neighborhood. Being of a liberal disposition, he allowed all who had a mind so to do to supply themselves freely. They readily availed themselves of his offer during the past summer, when the city water had a pretty nasty taste—though, as the small amount of sickness in Binghamton during the hot months proved, it was by no means unwholesome. It fell upon a day—and a very recent day at that—however, that a sportive kitten toppled over into the well and was drowned, whereupon i was determined to draw out all the water and clean the well thoroughly. There had been no cleaning for years, and the kitten's death was seized upon as a good excuse for having one. The water was accordingly drawn off and a man sent down to scrape the bottom of the well. In the first bucketful he sent up were discovered the remains of three toads, a dead cat, and the sleeves of an old shirt in which had been tied up and consigned to a watery grave, no less than six small kittens! In the next bucket which was hauled up, was a peck of earth worms such as are called "nightwalkers" by fishermen. They were all dead! This was the last straw. The owner of the well, convinced that his well (as is commonly the case in cities) has been used as a dumping place for dead animals, refused to try any further experiments in the cleaning line, and instead, had his much-vaunted well filled up and rendered useless for the future. He now drinks the city water which he onbe so contemptuously despised.—*Fire and Water.*

THE YOUNG BUILDING—MARKET AND SPEAR STREETS.
KENITZER & BARTH, ARCHITECTS.

FLOOR TESTS AT THE YOUNG BUILDING.

A DISTINGUISHING feature of the architectural profession of the Pacific Coast is its prompt recognition and generous encouragement of local enterprises when established on a basis that entitles it to confidence. This is especially true at the present time when the remarkable advancement in the methods of building construction creates a demand for new devices whereby the maximum of efficiency and strength is attained and valuable space economised.

The Western Expanded Metal and Fireproofing Company affords a conspicuous instance of the alacrity with which our architects adopt new and meritorious ideas and the immense demand which has followed the introduction of the productions of the company indicate, more than words can describe, the confidence entertained by builders in their adaptability to structures of every class.

The five-story, steel frame, brick and stone building situated on the corner of Market and Spear streets, and owned by Wm. W. Young, Esq., is one of the latest of considerable magnitude that is fireproofed throughout with expanded metal floors and laths and offered a first class opportunity for a scientific and convincing test of the real merits of the inventions. The test was made on Monday, October 5th, in the presence of several architects of eminence, a number of first-class builders, the owner and many interested spectators, under the supervision of all the officers of the company.

The test was as follows:

San Francisco, Cal., Oct. 25, 1898.

Office of Kenitzer & Barth,
601 California St.

Description of test of an arch constructed by the Western Expanded Metal & Fire Proofing Company in building S. W. cor. Market and Spear streets.

Span of arch 16ft. from centre of bearing. Steel straps 3/8"x5" placed 4 ft. on centers. Thickness of concrete 4 inches with No. 16 expanded metal 2½" mesh at bottom of arch. The concrete for arch is made of the following proportions: 5 parts of cinders, two parts of sand and one part of Josson Portland Cement.

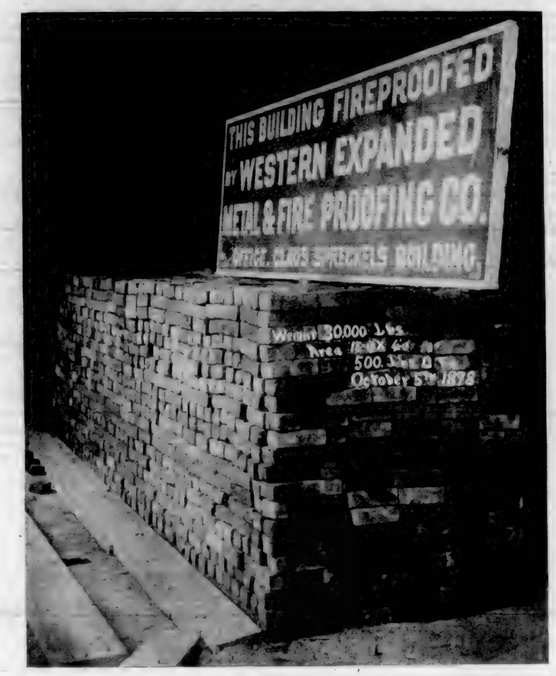
A uniform load of 500 lbs. per square foot was applied over an area extending from center to center of straps and between flanges of the supporting beams—equal to an area of 60 square feet and a uniformly distributed load of 30,000 lbs. The supporting beams were previously propped up so as to guard against their deflection.

The loading was effected by means of bricks, each brick weighing 6.2 lbs. With a load of 200 lbs. per square foot uniformly distributed, the deflection of arch at the center registered ⅛ of an inch, with 287 lbs., nearly ¼ of an inch, with 350 lbs. it deflected 5-16 of an inch, with 450 lbs., 7-16 of an inch.

The loading was then discontinued and allowed to remain on over night. On examination the following morning, it was found that the deflection had not increased. Loading was then resumed until 500 lbs. per square foot was reached, the total deflection then registered ½ of an inch. The load remained on for two hours with no increase in deflection.

On removing the load in the same manner as it had been deposited, the deflection diminished exactly corresponding to the deflection as it had been caused by loading the arch and at the time all the load was removed, the arch had straightened to its original position. It remains to be stated, that the concrete of which said arch is composed, was only six weeks old at the time of testing.

Respectfully, KENITZER & BARTH.



It is but fair to admit that all the gentlemen present were amazed at the solidity and elasticity shown by the floor under the exacting conditions.

It is not surprising therefore that the company reports so rapid an expansion of its prosperous business and that it is being intrusted, in a constantly increasing degree with the interior construction of most of our largest buildings. The great ferry building is a monument of the excellence of its methods which were adopted by the State Harbor Commissioners after the most searching investigation and the new San Francisco Hall of Justice, when completed, will be another instance. Neither is the list of great buildings the company has undertaken complete, that does not include many in Los Angeles, Pasadena—notably the Green Hotel Annex, and others of the larger cities of the State.

Not only for economy in weight of material is the expanded metal and fireproofing distinguished but for a sensible amount of remarkable space saved by their use.

Moreover, it should not be forgotten, the Western Expanded Metal and Fireproofing Company is a local industry, owned, controlled and managed by San Francisco men. The factory is at Third and Townsend streets and interested parties are invited to call and inspect it.

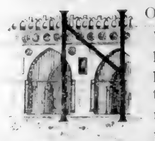
In the advancing prosperity of San Francisco, the company will be a large factor in the new era of scientific reconstruction which is about to dawn.

KEELY MOTOR UP-TO-DATE.

PROCEEDINGS OF ENGINEERS' CLUB OF PHILADELPHIA

BY E. J. SCOTT, ACTIVE MEMBER.

[CONTINUED FROM LAST NUMBER]



OW, as to the electrical features of the vibrodyne. Assuming that the compressed air flowing through the tube performed the office only of a starter, that it produced the conditions in the machine necessary to allow a more potent force to act, what force was applied by its action? The construction of the machine points directly to electricity acting through magnetism. If Professor Lascelles-Scott took the apparatus apart, he must have discovered the mode of its operation. The unnecessarily heavy parts of the machine afforded every opportunity for the concealment of the small wires necessary for the power developed, or the bolts which run down through the floor to hold down the iron foundation could have served as conductors. It was an easy matter to bring a current to electro-magnets concealed in the mine inteaior disks, and no great amount of ingenuity would be required to construct a switch, operated upon both by the compressed air and magnetism, which would cut the magnet into or out of circuit at the proper time to attract the armature on the end of each revolving spoke. Had there been nine spokes as well as nine opposing disks, the wheel would have got on a dead center, and could not always have been started; but with only eight spokes there were always some in a position to receive a magnetic pull before the magnets were cut out of circuit by the opposing disks being exactly opposite each other. The evidence of design here is sufficiently strong to warrant the conclusion that the wheel is operated by electro-magnets. Apergy would not have required this arrangement.

Keely said to the writer that the hub of the wheel was loose on the axle, and that when running at a high rate o speed he could knock out the axle and the wheel would continue to turn in space. Such an exhibition would have been interesting, and would have convinced the writer that the force was not magnetism, which was the chief object of the exhibition, but he did not do it, nor did he offer to do many other things which he spoke of as being easy, and which would have astonished the investigators.

It was decided on the occasion of the second visit by both of the investigators, that magnetism had nothing to do with the jar experiment, as the motion of the bodies was uniform, which it would not have been if actuated by a magnet. The theory of a tube made every thing plain, and Mr. Burk has had constructed a jar which he used in explaining the phenomenon before the Spring Garden Institute last winter, using an air pump for the transmitter.

Within half an hour after the close of the last visit, Mrs. Moore called on the writer at his residence to learn of him his conclusions. He explained to her fully the use of the platinum tube, and advised her to have the experiment repeated and convince herself of the fact by taking a pair of pincers and pressing the sides of the tube together, when the revolving wheel would stop; or to cut for herself a section from the middle of the supposed wire while the machine was in action and examine it. She consented to have the experiment repeated in her presence and permit the writer to make the cut, but he told her she could never persuade Keely to repeat the experiment for such a purpose. She was more than half convinced, but afterwards saw the Professor and asked him to see the writer on this subject.

The English scientist came the same evening, and for four hours the events of the day were discussed. He gave an account of his investigations in vibratory physics, and particularly in reference to the simultaneous explosions of two or more powder mills situated at considerable distances apart, the result of vibration; and considered the phenomenon analogous to some of Keely's experiments. Criticisms by the writer on Keely's work, and inquiries as to the discoveries the Professor had made, led up to the Professor's part in the preparation of the second jar, the one used in the experiments of that day. He told of his care in procuring the distilled water, and in obtaining the exact weight of the globe and disk which were placed in the jar. When asked if he personally placed the weights in the jar or saw them placed there, and saw the jar sealed, he admitted that he did not, but that Keely did this himself. He was asked, "Do I understand that you, a professional expert in physics, would trust to the man you are investigating to do these things, and then have the conscience to make a report to your employer of the result of such an investigation?" He mildly admitted that it would have been better to be present.

Likewise when the platinum tube was mentioned, he stoutly denied that it was a tube, saying that he had several samples of the platinum wire and knew it to be solid. He had taken samples of almost everything he had investigated. When asked where he got his samples and whether he had cut them from wires he had seen used in the experiments, he said he had taken them from a reel of the wire.

The Professor agreed with the writer that the best way to prove or disprove the use of the Tube would be to have the experiments repeated and allow the writer to show the character of the wire employed. The writer told the Professor that Keely would never make such an exhibition under those conditions. The Professor visited Keely the next day, Sunday, and on the following day informed Mrs. Moore that Keely had declined point blank to repeat the experiments, "just as I was told he would do," he added. He suggested to her the absolute necessity of Keely doing this in his own best interest. Keely could not, however, be induced to do so. The Professor left the city at once, and under the circumstances, as he explained, thought it best not to appear a second time before the Franklin Institute.

The explanation here given is not, of course, a complete explanation of all that is to be seen in Keely's laboratory. Indeed it would take more than four visits to look over, which is all that was permitted, the apparatus which was accumulated in a quarter of a century. It is enough, however, to show that nothing was shown in motion which required a force to move it which is not already known. The manner of the use of such forces, as used in these experiments, would probably, in the minds of most people, throw a doubt upon the probability of Keely's knowledge of any more mysterious force.

THE END.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL, and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

See a full size working model at our store.

For Sanitary Reasons

You Should Specify the

Brown Brothers' Cold Drawn Seamless Copper House Range Boiler.

The smooth copper surface is heavily tinned inside. This absolutely insures against corrosion or rusting of any kind and affords no rusting place for sediment. You alway get

Clean Hot Water

own Boilers are made of two pieces of cold drawn copper, united under great hydraulic pressure, so that they are practically one piece. No seams nor rivets, means freedom from leaks. The inside spiral rib guarantees against collapse. Ordinary weight boilers stand a pressure of 150 lbs. to the square inch; extra heavy, 200 lbs.

Boiler Booklets sent on request.

Information Willingly Furnished.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

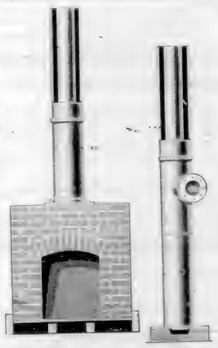
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See **CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.**

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

UNFAIR COMPETITION.

Our recent announcement that inferior goods had been sold and billed on the Coast as our goods, and that our trademark numbers had been counterfeited, has disclosed an even greater extent of these practices than we had supposed to exist. To make the resulting damage to the reputation of our goods as small as possible and to protect our would-be patrons we repeat:

All our catalogue goods, except those listed by us as manufactured by others are stamped with our name "Keuffel & Esser Co." or our initials "K. & E. Co." and where there is room for it, with our trademark trademarks or . **We never stamp our goods with catalogue numbers only,** and goods so stamped are therefore not ours. All our goods are fully warranted to conform to the description we give of them in our catalogue and to be of the quality and grade specified. The "Vulcan" Locks

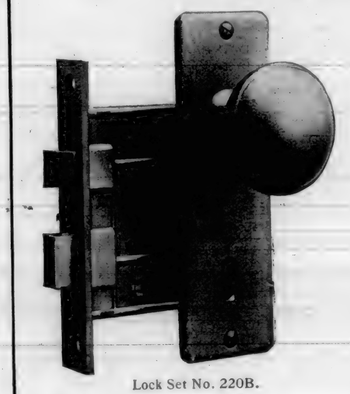
All Wrought Metal—with "Compensating" Hubs.



Lock Set No. 220B.
One-half Actual Size.

Our General Offices in New York have recently received the following unsolicited letter from a prominent builder and contractor. Believing that the statement of experience it contains will be of interest, we reproduce it below.

An Artistic Brochure on Vulcan Locks, also a Catalogue of 90 pages, will be sent on request.

The Yale & Towne Mfg. Co.

LOCAL OFFICE:
Mills Building, San Francisco.

GENERAL OFFICES: 9-11-13 Murray St., NEW YORK.
WORKS: Stamford and Branford, Conn.

OFFICE OF A. BEINHAUER,
124 Maiden Lane,

NEW YORK, July 11th, 1898.

The Yale & Towne Mfg. Company,
9-11-13 Murray Street, New York.

Gentlemen:-Having lately had occasion to use and apply your "Vulcan Locks" in the Anderson Building, 12-14-16 John Street, I take pleasure in mentioning the fact that in the application of these locks there is a large saving of labor as compared to the ordinary CAST-case locks.

The difference, as I found it, was that while a man put on six to eight of the latter, he could in the same space of time put on twelve to fourteen "Vulcan Locks," thus decreasing the cost of labor to a considerable extent.

Another feature about these "Vulcan Locks" is that while they give as good service as any cast-case lock of their denomination, they do not require as much cutting away of wood in the lock-rail, thereby strengthening the door to an appreciable extent.

Wishing you all success with your "Vulcan Locks," I remain

Yours truly,
(Signed) ALFRED BEINHAUER.

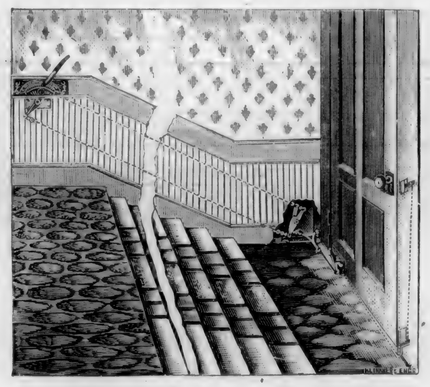
No. 3446 Nineteenth St., S. F



VOLUME XIX. NOVEMBER 20th, 1898. NUMBER 11.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

THE SUCCESSFUL architects who participated in the great Hearst competition and gained the coveted rewards have all arrived on this side of the Atlantic and by the time this number of the CALIFORNIA ARCHITECT AND BUILDING NEWS is issued most. if not all, of the visitors will have reached this city and be busily engaged in studying the environments of the University of California at Berkeley. It is said that before leaving Europe all the successful competitors arranged to meet in New York the latter part of November and then proceed in a body to California. The date of arrival will be duly announced. Beyond a corporation reception presided over by Mayor Phelan, which, it is expected, will be tendered the distinguished strangers, no general movement seems to have been made for entertaining them by local architects so far as heard from. Perhaps it is thought that a welcome from personal members of the profession will answer every purpose but it appears to us that the opportunity for a combined and representative acknowledgment of the presence of the strangers would be a highly gracious attention to accord. The Hopkins Art Institute could be secured for the purpose and every student of architecture ought to be allowed the chance of making the acquaintance of these giants of the profession and to listen to the words of wisdom and enlightenment that is sure to fall from their lips. The hospitality to be extended to these eminent men ought to be equal to that displayed by the people of the Dutch metropolis at least. But this can safely be left to the right feeling of our local architects, who will remember that the reputation of California hospitality is very great and extended and that it will be their pleasant duty to see that it suffers no diminution at their hands.

The presence of these accomplished gentlemen ought to be of equal value to themselves and to local architects as well. They will be interested in observing the adaptation of the rules of construction to the peculiar conditions that exist here unlike as they are, to those of any great capita

in the world. Neither need our architects be ashamed of the results of their labors. There are plenty of examples among our public buildings, mansions and business blocks that are monuments of original design and difficulties overcome. Fortunately there are but few "gems" of architecture like the Chronicle and Hearst buildings to blush for, but such blemishes are more than offset by others which are the admiration of every one who makes building construction a serious study.

The impression that the splendid site of the University will make upon these gentlemen can be faintly imagined. Such another location, no institution in the world possesses. A combination of vast extent of mountain, sea and plain, is rarely to be witnessed. It will be an inspiration that will be quickly grasped by the strangers and their designs can but receive added beauty and increased impressiveness after personal contact with the sites and scenes where their mental embodiments are to take visible shape.

DESTRUCTION OF THE BALDWIN.

THE total destruction of the Baldwin Hotel by fire is to be regretted. That such a fate was to be the ultimate destiny of this building was fore-ordained. It was a monument of lavish expenditure and depraved architectural methods. The destruction is so complete that a new structure will now be required. The location is unequalled for hotel purposes and a new one surpassing in magnificence anything in the west will probably take the place of the building that is to day in ashes. The site for a grand opera house could not be excelled. It is to be hoped that when the new hotel is planned a dramatic and musical temple will be part of its equipment. The site is too central to remain unoccupied longer than the time required to replace the odd structure. California architects will here have an opportunity for acquiring new distinction.

PASSING OF THE OLD BUILDINGS.

A CHEERING indication of the general revival of faith in the future of this great city is the fact that numerous owners of down town buildings that were at one time occupied as offices, professional or otherwise, are contemplating, in many instances, either total demolition of their out-of-date holdings or else such a transformation or rearrangement of the interiors as to make them quite as desirable for business purposes as those lofty and complete structures that have been erected during the past three years in other sections of the city. It would seem that the natural wholesale center is in that section bounded by Market, Kearny and Clay streets and there is no reason why it should not remain within these boundaries for all time unless the business public should be driven away by a lack of proper facilities for transacting their commercial affairs. It ought not to be forgotten also that in these days of telephonic connections the necessity of a location within easy proximity to the center of exchange is not so great as formerly. It might be remembered also that within the past forty years one change has been made that carried the commercial center from Dupont to California street and there is nothing to prevent the same thing happening again. The actual trend of finance is to the south of California street. Banks and other financial institutions are slowly but surely moving in the direction of Market street where the crowd is concentrating. The new Federal buildings at Seventh and Mission will have a powerful influence upon locating a new business center. Something ought to be done towards retaining what is left of California street as the commercial center and a general movement that will eliminate the old and obsolete office building as in order. The early architects of this city have much to answer for. There is hardly an architectural feature of the early days that could, with advantage, be retained. Such unscientific treatment of floor space as these early edifices show excites the derision of up-to-date architects.

The Merchant's Exchange is a conspicuous example of absolutely defective architecture. It ought to be torn down forthwith. Fully one half of its superfices is wasted. It occupies as much ground as the Mills building—compare the two structures as rent producers. It can be easily established that in replacing any of the old style buildings fully one half more space can be utilized in its present cubical area than now and not taking into account the possible increased height either.

Therefore it is to be hoped that the elimination of the old style building, so auspiciously begun will be continued until every one of "those monuments of early days" will be allowed to disappear. A chance is here given for the architectural adornment of the city's streets. Here a responsibility is laid upon the profession that should never be lost sight of.

DR. BAZET'S MICROBE HATCHERY.

AT a recent meeting of the local Board of Health a proposal was made by Dr. Bazet, a member, to abandon the plan of erecting a stone or brick hospital for the county and substitute a cheap temporary affair built of wood that could be destroyed every "ten or fifteen years or so" and another built in its place. This process to continue indefinitely. The advantage gained being in the saving of cost between a first class and a make shift hospital. Dr. Bazet in his remarks advocating this plan of his on the occasion referred to, stated that a wooden hospital would be very cheap and could be made at the same time "very attractive". The learned doctor, however, neglected to state whether a wooden affair would be attractive to the patient or to the microbes, whose propagation was to be thus encouraged until such a time as the hospital became thoroughly infested when it would be burned down and another one erected. Such a hospital, Dr. Bazet advocated in the interest of science admitting that medical science was impotent in its capacity to remedy evils requiring only cleanliness and antiseptic solutions for completely extirpation. Dr. Bazet is too competent a physician to have much faith in the claim of a certain medical charlatain, that he could cure by drawing the microbe responsible for the disease out of the patient with the aid of a powerful magnet but his proposition to make the conditions about his hospital "attractive" seems to indicate something of that sort

Dr. Bazet's proposition seems to be open to serious objection in more than one respect. He deliberately favors a plan that encourages the accumulation of filth, a plan also that has never been adopted by any first class municipality in the world and that originated in the tropics as the fruit of military exigency which required certain precautions against the spread of virulently infectious diseases never met with in this latitude excepting in sporadic form. In the new hospital no infectious diseases will be treated, separate provision being made for occasional cases received. It would seem to be a mean thing for a great, wealthy city, like San Francisco, to ask the poor wretches dependent upon it for care during wasting illness, to go to a hospital no better built than a pioneer shack or an Indian tepee. The management of such a hospital would also be seriously affected by the temporary character of the buildings. The effort to keep affairs in perfect condition would be dominated by the knowledge that in a short time the hospital would be destroyed any way. Does the Board of Health wish to perpetuate the scandals, conflicts and corruptions which always accompany the erection of every municipal structure and leave such a legacy to their successors? Is it not known that in ten years a movement for the removal of such a temporary hospital would be demanded wherever it may be placed? Would Mr. Phelan care to distinguish his administration by a measure that would bring ridicule upon it forever or have his name associated with the only structure erected during his term of office that would require obliteration, on the score of public health, in ten years or so? It would be thought not.

The fact is that Dr Bazet's plan has been thoroughly considered by scientific minds on both continents, and it has yet to be learned, the Glasgow instance notwithstanding, of one single municipality that has even seriously considered its adoption. The great St. Luke's hospital of New York, erected at a cost of $3,000,000, and the finest in the world, is one that will last for generations. The new Chicago hospital is permanent and the cities pride. London's hospitals are of the most substantial character and every where except possibly in China or India where plague is always rampant and where hospitals are necessarily temporary in their character, these monuments of the magnanimity of communities are strong, substantial and architecturally beautiful.

The plan of Dr. Bazet, to a layman, appears to be rather for the propagation and cultivation of diseased microbes, and designed to convey infection to the thousands of those unfortunates who in the "ten or fifteen years or so" will be obliged to accept its ministrations and through them the entire community will have to endure an ever present and increasing danger from infection.

A Draughtsman of experience desires to obtain employment in San Francisco or some California town. Would purchase an interest in an established office.

Address—C. E., California Architect and Building News.

COLOR IN STREET ARCHITECTURE.

THE GREATER attention given to exterior coloring is a pleasant feature of building of to day. Architects have heretofore, evinced timidity in advising the use of more positive coloring for decorating buildings or have been restrained from following their own artistic conceptions on the subject by property owners who, as a matter of course, have the final word and, as a general thing, hesitate to take the initiative in defiying long established custom. It is a sign of progress in the right direction when color as an adjunct of street ornamentation is receiving more intelligent attention from the architect. The people of tropical or semi-tropical countries seem to understand this subject better than we of temperate zones. The bright colors either in combination or otherwise that are to be observed in all communities of Southern people is a feature of the most pleasing character to travelers and is frequently remarked. These people are simply following their own artistic instincts of beauty and fitness and while the effect is sometimes grotesque and extravagant yet the general result is bright, pleasing and cheerful.

The Saxon on the contrary is disposed to confine all color to the interior and to regard any effort to make the exteriors of their dwellings, otherwise then dull, as a violation of good taste. The Greeks, whose judgment in all matter relating to absolute correctness in art was undeniable even covered their temples, constructed of the purest Pentalican marble, with color and the statues of Phidias, in their opinion, derived added beauty from applied colors by making them more like the living subjects which these unequalled statutes were carved to represent. Under such skies as are usually to be observed in San Francisco where cloudy days are the exception and bright sunshine the rule, a greater latitude in color for outside adornment ought to be permitted. Market street, from the ferry to Sixth represents a most monotonous effect of color, occasionally a yellow or brick red but almost altogether drab, cheerless, dispiriting, inartistic. There are some bright instances of street color, notably on the crest of California street, where half dozen handsome structures afford an example of the pleasing effect of decided tints. How much would be added to the appearance of the new City Hall if, instead of an exterior covering which now only emphasizes the cheap material of which it is constructed and detracts from the real beauties which the edifice possesses, it were colored in white or a light terra-cotta. The expense would not be great and the result would be a distinct gain. There is a building near Mason and Ellis streets whose exterior is glazed brick of a deep bottle green. The effect is beautiful.

In the city of Mexico, opposite Hotel Iturbide, there is a mansion of a Mexican grandee, as large as the Flood residence and constructed in Spanish style, with a large *patio* in the center, filled with tropical foliage and protected from the street by a splendid wrought iron grill. The whole exterior of this house is veneered with light blue and white porcelain tile, imported from Paris at enormous cost but producing a most striking and beautiful effect. It would require great courage for a builder in this latitude to follow such an ex-

ample but there is no house in the United States that is its equal and very few builders that could afford it.

To make street color more effective will require time and the destruction of old established prejudices but that a harmonious result would be accomplished and the general appearance of our cities be greatly enhanced few will doubt.

MEMBERS OF THE ARCHITECTURAL STUDIO HARD AT WORK.

THE members of the Architectural studio of the Mark Hopkins Institute of Art have buckled down to hard work for the Winter season. At the last monthly competition held on November second nearly every member presented drawings and sketches which were ably criticized by Mr. Coxhead. The subject of the competition was "Given the intersection of two narrow and crowded streets to cut away the buildings on the corners so as to relieve the traffic and produce an imposing architectural effect. The schemes followed the plan of the London "Circuses" only they were octagonal instead of circular and the general criticism was that sufficient importance was not given to the skyline. The sketches were the preliminary studies for a park bridge, the subject of the next competition, finished drawings of which are to be presented on the first Wednesday in December.

The Class in History, after having pursued, under the direction of Mr. Sanders, the subjects of Prehistoric, Egyptian, Babylonian, Assyrian, Persian and Jewish architecture is now fairly advanced in the study of Grecian architecture. The life class still retains its hold on the members and is both profitable and interesting.

At a recent meeting it was decided to compile a paper for publication in the CALIFORNIA ARCHITECT AND BUILDING NEWS on the greatest architectural need of San Francisco. It is hoped that by showing how and where the architecture of the city may and should be improved that popular interest may be aroused that will result in many needed improvements and architectural reforms.

THE ACOUSTICS OF TRINITY CHURCH.

TRINITY Church in this city is one of the finest ecclesiastical structures in the state, and will comfortably seat nine hundred persons. It is built in the Old English style and architecturaly is attractive and complete. Nearly $200,000 is invested in the edifice and its splendid adornments. Its congregation is aristocratic, wealthy and influential and its rector, scholarly and devoted. Everything that the most exacting worshipper can possibly demand is found in this sacred edifice but, after the church building was newly occupied it was discovered that the acoustics were fataly defective and that no matter how loud the clergyman might shout only those in the immediate proximity of the chancel could understand what was said and even then but imperfectly. The sound ever berated again and again and became a mixed jumble of discordant words. Even the tones of a powerful organ failed to make the proper impression and the most exquisite harmonies were distorted by the sharp and protracted echoes that followed the sounding of the key board. The result is discouraging to the last degree and efforts have been and are being made to remedy the evils or at least mitigate them. It is thought by some who have studied the case that the interior architecture of the church is faulty and that no absolute cure will be accomplished until drastic changes are made. Over the junction of nave and transepts there is a tower of large dimensions, open to the roof and extending several feet above the ceiling of the church. This tower forms a great square cavern into which the words of the preacher and the tones of the organ are first carried and are then shattered against the four walls into a mass of unintelligible echoes. It is believed that the whole fault lays in the defective construction of the tower. Some time ago, following the suggestion of an architect, the west walls of the church were hung with silk curtains but the result was not noticeable. Lately a sounding board was placed over the pulpit and an improvement was apparent at once. The sounds were thus carried away from the tower and into the nave. But the defects have not yet been entirely remedied. It is now proposed to string innumerable wires across the opening to the tower and possibly the effect of this experiment will be an improvement but architects generally are disposed to believe that nothing but an entire rearrangement of the architecture of the tower whereby the great opening may be completely or partially closed, will eliminate the distressing echoes and purify the acoustical defects. The problemn is an interesting one and excites great interest.

THIRTY-SECOND ANNUAL CONVENTION OF THE AMERICAN INSTITUTE OF ARCHITECTS.

WASHINGTON, D. C., Nov. 1.—The proceedings of the Thirty-Second Annual Convention of the American Institute of Architects opened at 10:30 this morning in the Banquet Hall of the Arlington Hotel, with Mr. George B. Post, the President, in the chair, and with about 100 delegates in attendance from various parts of the country, among whom were: George B. Post, Robert W. Gibson, Julius Kastner, Wm. Martin Aiken, John M. Carrere, T. E. Crossman, Charles I. Berg, Edward Kendall, Henry C. McKey, New York; Alfred Stone, Ed. J. Nickerson, George A. Frederick, Edward F. Eley, Providence, R. I.; W. L. B. Jenney, Charles S. Frost, G. A. Trent, Robert Craik McLean, editor *Inland Architect*, Chicago, Ill.; A. W. Longfellow, Edwin J. Lewis, Jr.; A. G. Everett, H. Langfort Warren, Boston, Mass.; C. M. Bartberger, Thomas Boyd, T. D. Evans, S. F. Heckert, Pittsburg; F. H. Young, Jacob Agne, Jr., Utica, N. Y.; C. A. Wallingford, Bernard Vonnegut, Indianapolis, Ind.; Guy Kirkhorn, Springfield, Mass.; A. W. Hayward, J. W. McLaughlin, George W. Rapp, Gustav W. Drach, A. O. Elzmere, Cincinnati, O.; Isaac Ditmaes, A. G. Thomson, A. Porter, L. D. DeCorb Berg, Walter Dickson, Brooklyn, N. Y.; Frank C. Baldwin, John M. Donaldson, A. W. Chittenden, J. S. Rogers, Jr., George D. Mason, Detroit, Mich.; Addison Hutton, Frank Miles Day, Philadelphia, Pa.; Charles F. Swinefurth, Levi T. Schofield, Cleveland, O.; J. W. Yost, Columbus, O.; L. Boucherts, Youngstown, O.; J. Foster Warner, Rochester, N. Y.; J. H. Pierce, Elmira, N. Y.; E. C. Ernest Lamb, F. B. Pyle, A. Didden, T. F. Schneider, Robert Stead, James K. Taylor, James G. Hill, J. L. Smithmeyer, Washington, D. C.; M. S. Mahurin, Fort Wayne, Ind.; W. H. Conway, George H. Helme, Springfield, Ill.; E. B. Green, John H. Coxhead, C. Cary Buffalo, N. Y.; J. O'Rourke, Newark, N. J., Robert E. Dexter, Dayton, O.; F. D. Allen, Juliet, Ill.; Prof. Trowbridge, Cornell University; Arthur N. Gibb, Ithaca, N. Y.; Henry Brunse, F. B. Noel Wyatt, E. G. Lind, Baltimore; Md.; N. W. Mortimer, M. S. Malewin, Fort Wayne.

The address of Welcome by Mr. J. C. Hornblower in behalf of the Washington Chapter, was short and to the point. This was followed by Commissioner Wight who said:

"I extend to the American Institute of Architects a hearty welcome on behalf of the D strict Commissioners of the District of Columbia and on behalf of the District itself, to all I give a kindly welcome, and venture to express the hope that it will be as agreeable for you to be with us as it is to us to have you here.

"Last week it was my privilege to welcome to the District another convention, that on Municipal Improvements. They took up for consideration the subjects of sewerage, street improvements, electric lighting, etc., all of which were important, and in which we, as a city were greatly interested, but not any more so than the matters that will be dealt with here by this Institute. This meeting of your Institute is very timely in coming to us when we have begun some important steps in the matter of the architecture of our public buildings. We have expressed ourselves as of the opinion that the designing of our public buildings and bridges should not all be the work of one person, and our experience leads us to believe that we have taken a wise step. We believe that the competition in the matter of public bridges and grounds should only be open to those who have shown that they were able to design such structures, so that the result may be designs that will be an addition to the architecture of this District, both as to beauty and suitability for the purpose for which they were designed.

"Another step upon which we insist is that there shall be no sky-scrapers in the District of Columbia; to that end we have enacted that the maximum height of buildings shall be 90 feet, unless on business avenues of 160 feet in width.

"We trust these matters will commend themselves to you and will receive your support. I therefore again welcome you in the name of the Commissioners of the District of Columbia."

PRESIDENT'S ADDRESS

"The programme of the Thirty Second Convention of the American Institute of Architects as usual requires that the proceedings shall be opened by an address from your president.

"On former occasions I have directed your attention to the unexampled rapidity with which the fine arts have developed in America since the first organization of this association, and to the prominent part taken by the architects in this development; to the growth of the association itself from a body weak in numbers and weaker still in the influence of its members individually and collectively, to an organization extending over the length and breadth of this enormous country; an organization which has become a recognized power in all questions directly or indirectly pertaining to architectural art.

"I have directed your attention to the dangers which menace our art, and to the fact that if true to itself the future of the profession is clearly in the control of this Institute.

"I now desire to extend to its members my most hearty congratulations, for although a period of general depression in individual business, the past year has been marked by three events which will form an era in the history of American architecture.

"The wise Secretary of the Treasury, the present honored head of that Department which is the great builder for the Government, has not only established a most important precedent and practically made a public recognition of the fact that educated talent is essential to economy and success in the work of our profession, but more important still, that there should be no politics in art:—by the appointment of a Supervising Architect after a most careful and exhaustive competitive examination conducted by a specially appointed Civil Service Commission, consisting of a Board of Architects of recognized position in their profession.

"For almost the first time in the last three decades we have seen architects in private practice selected by fair competition judged by expert jurors, for the design and erection of Governmental buildings. A practical recognition of the fact for years asserted by the unanimous vote of the profession that worthy architecture cannot possibly be secured, except by accident, from a Government office; no matter how great the ability of its chief, where the mass of bus ness in the maintenance and repair of existing buildings is so enormous that the work of design is of necessity largely delegated to assistants. Under these circumstances excellence must be at best a lottery.

"In all ages and in all countries employment for the design and erection of Government work has been the maximum reward of professional distinction. Consequently the structures erected by the Government of a country have been generally and properly accepted as the most reliable and decisive proof of the civilization of the period and race by which they were produced.

"Alas for the verdict of future ages upon the excellence of the art and civilization of America in the latter half of the Nineteenth Century, if judged by such monuments as the Pension Building and the Post Office, and the great majority of structures erected from designs prepared in the offices of our Government.

"Unfortunately these buildings are built with extravagant excellence and will stand for ages a travesty upon the art of the country, a reproach to the intelligence of those in power who have refused to listen to the urgent and repeated opinions of those qualified by education and experience to give advice, and have persistently refused to use the means always at their hands to procure designs which should at least represent the average skill and economy daily shown by the architects of the country in private practice.

"It is the clear duty of this body, the great representative society of American architects, never for an instant to relax its efforts until such time as the creation by the Government of such artistic monstrosities shall be impossible.

"We have seen by the recent precedent established by the Treasury Department that persistent protest and untiring effort will surely bear its fruit.

"This Institute should never pause in its exertions until Congress has passed the necessary amendments to make it

mandatory that for the design and construction of each important building to be erected by the government in any of its departments, there should be appointed directly or by limited competition, an architect whose ability has been thoroughly proved by success in private practice, and that the fees paid for his services by the Government shall be those recognized throughout the civilized world as the proper and just recompense for such services—the fees rehearsed in the Schedule of Charges of the American Institute of Architects, and uniformly paid by individuals and corporations in all of our great business centres.

"Provisions should be demanded for the appointment of proper juries of award composed of experts in the case of all competitions, and to provide for the expenses of such juror as well as for the payment of a moderate and proper fee.

"For the first time in its history the Institute has established a permanent headquarters. As is eminently proper the permanent home of the national organization is located in the National Capital

"In the march of events the institution has outgrown its old code of laws and under a new constitution you are called upon to consider a new code of by-laws. It is a matter of regret that so large a part of the time of this convention must be of necessity devoted to this subject, and it is earnestly hoped that your consideration of the subject may be so careful and your decisions so wise that the time of future conventions may be free for the discussion of the mass of subjects of more general interest than the minute details of interior organization."

This left the meeting open for the general order of business, which opened with the report of the Board of Directors, read by Mr. Alfred Stone, the genial secretary of the Institute, who is so ably fitted for the responsibilities of the arduous position which he occupies.

The report is as follows:

"To-day the Institute enters upon a new era in its history which is fraught with no little anxiety. The step it has taken without precedent, as no similar society has broken away from the commercial metropolis of the country and established its home in the National Capital. It may therefore, properly be called an experiment, and is one that will depend for its success upon the individual and united efforts of the members of the Institute, and may easily prove to be a failure without such effort. The first way in which it may make itself manifest is by an increase in its membership, which the proposed by-laws, if adopted, will facilitate. It is only by a membership large in numbers and representing the best equipped members of the profession who not only combine to a high degree professional skill and training, but exalted views as to the ethics of the profes ion that the Institute can realize the full advantage of its mission and reap the benefits of its new departure.

"The question of the present home for the Institute has been an ever-recurring subject for consideration, and many years ago an effort was made to procure a building fund, but not until after the passage of the following vote on February 11, 1898, was any real progress made:

"Voted—That a committee of three be appointed by the president to secure a lease of the so-called 'Octagon House,' Washington, D. C., for a term of five years if possible, for a rental not exceeding $360 per year, and with further power to formulate a plan, obtain funds and put the house in condition for occupancy."

It was also voted "That the committee be authorized to issue debenture bonds of small denominations to an amount not exceeding $5000, and that the form of the bond is to be approved by the Executive Committee before issuing the same."

In pursuance of that vote the president of the Institute, in accordance with instructions of the Board of Directors, appointed Frank Miles Day, Robert Stead and Wilson Eyre, Jr., a committee to procure a lease of the Octagon House and put it in a condition for occupation, and issue bonds to the extent of $5,000 to meet the expense thereof. To-day we shall open and enter upon the occupation of our new home and the enjoyment of the fruits of their labors.

The passage of this vote was the outcome of the report of the Washington Chapter presented to the Board of Directors at that time. Among the advantages set forth in this report were: That it afforded the broadest field for the Institute to obtain national legislation in relation to art and construction; that it could here more efficiently advocate the establishment of a Government testing station and a National Architectural Museum, and would be in a position to make its influence felt in the methods adopted by the Government for procuring designs for national buildings, which has been so successfully inaugurated under the direction and by order of the Secretary of the Treasury, the Hon Lyman J. Gage, an honorary member of the Institute and an efficient supporter of the best interests of the profession.

A fuller and detailed history of the movement and its results will be visible at the reception, to take place this afternoon, and will be heard in a report of the chairman of the committee which has so successfully accomplished the task set before it.

At the last annual meeting the conduct of the competition for the Pennsylvania State Capitol furnished an engrossing todic of consideration, but without producing the desired results. In fact, the outcome is, if possible, still more discreditable to the State than was anticipated, but in other quarters several notable competitions which have been conducted with fairness and in compliance with ethical rules of practice although they may not have resulted to the individual satisfaction of each and every individual competitor, and it is not improbable that the publicity which was given to the action of the Institute in the matter of the Harrisburg Capitol has not even greater effect than if it had resulted in the adoption or the course advised by the Institute.

The more than questionable conduct of the commissioners, their unjust treatment of its professional advisers, the defeat of the machinations of the firm that expected to capture the prize and the subsequent still more scandalous action of the commissioners has been an object lesson to what ends publicity and unfair dealings may lead, and it is believed that the State of Pennsylvania has but entered upon a gigantic scheme that will extend through many years and be productive of still other and larger results to the discredit of the State and with heavier demands upon its treasury. In view of the failure of the Pennsylvania State Capitol competition and the success of that for the New York Public Library building, it has been suggested by a distinguished member of the New York bar, that the Institute appointed a committee to have power to employ legal counsel to prepare a formal programme of competitions and have it recognized in legal enactments and ordinances authorizing commissioners to secure an architect by means of competitions; such an act or ordinance might make it legally incumbent upon a corporate body or even upon a State itself, to pay promised fee, which the State of Pennsylvania successfully dodged, with no legal redress for the architects employed by it. There is,

VOL XIX № II NOVEMBER 1898

however, something stronger than legal enactments by State or city, and that is the recognition of the unwritten law of ethics which a professional body establishes for its own conduct, and which will be respected by the public and will be complied with to just that extent with which it is respected by the profession and complied with by its practitioners.

It may be expedient to procure legal enactment; it is imperative that our practice be in accordance with professional ethics.

The letter ballots on the adoption of the amendment to the constitution have been opened and it is found that the amendments have been adopted with but eight negative votes out of 131 ballots sent in.

The consideration of the revised by-laws will be brought to your attention, and it is trusted that such action will be taken as will save the Institute from the necessity of devoting the time of its annual conventions to changes therein, and will insure a large and permanent increase in the membership of the Itstitute.

The deaths among the Fellows of the Institute since the Detroit Convention have been F. A. Coburn, of Cleveland, O.; Alfred Smith, of Chicago, and Elbridge Boyden, of Worcester, Mass. The latter was probably the oldest member on the rolls of the Institute, and contemporary with him was William W. Boyington, of Chicago, a former Fellow of the Institute, who died in Chicago on October 16, in his eightieth year. A memorial and resolution to his memory, prepared by Mr. P. B. Wight, F. A. I. A., has been received from the secretary of the Illinois Chapter.

The death of Oliver C. Smith, a Fellow of the Institute, occurred on December 1, 1896, but was not known to the secretary until after the publication of the proceedings of the thirty-first convention.

M. Charles Garnier is the only person among the honorary members of the Institute who is known by the secretary to have deceased during the year.

This was followed by the report of the treasurer, which showed that the receipts from September 10, 1897, to October 22, 1898, amounted to $3,916.08, the expenditure to $3,334.01, leaving a balance in the treasury amounting to $382.07. A separate statement was made by the treasurer on account of the expenditures and receipts for the Octagon House, whence it was shown that the receipts up to date amounted to $1968, the expenditures to $325.50, leaving a balance on hand of $1,642.50.

The report of the treasurer was referred to an auditing committee composed of J. G. Hill, C. I. Berg and Geo. A. Frederick.

Next on the programme was the reports of chapters, which was given in condensed form by the secretary, taking the chapters in their chronological order, as follows: New York, Philadelphia, Illinois, Boston, Cincinnati, San Francisco, Indianapolis, Washington, Michigan, Central New York, Buffalo, St. Louis, Pittsburg, Central Ohio, Worcester, Colorado, Southern California, and Brooklyn. These reports were referred to a committee to be appointed later.

Next in order came the report of standing committees, the first of which consisted of a humorous report from the chairman of the committee on foreign correspondence, which included extracts from the circular received by the committee during the past summer, calling attention to the First International Convention of Public Art, which was held in Brussels on September 24-28, and to which an invitation was extended. The report of that congress has not yet been received.

The report on education is laid over until later in the meeting.

The report on publication and library, as presented by its chairman, Frank Miles Day, is as follows:

"As chairman of the committee on publications and library, I beg to report that no meeting of the committee has been held, as no useful purpose would be subserved by bringing the members together. So far as the library is concerned, it is the condition shown by the report of the committee last year. As soon as the Octagon House shall have been put in repair the committee will endeavor to get together all the books and papers of the Institute, and will, with the approval of the Board of Directors, fit up a suitable library in the building.

"Regarding the relations of this committee to the publications of the Institute, we would say that the publications appear to consist entirely of the annual report, which is so adequately prepared by the secretary that the relation of the committee on publication in regard to it is merely *pro forma*."

No report was presented by the committee on conservation of public buildings, and the committee on building laws asked to be allowed to make their report later. No report was made by the committee on arts and sciences, but a paper was presented by that committee which was a review of the progress made in civil architecture and the decline of ecclesiastical architecture during the last half-century. The matter was ruled out of order at the present stage of the proceedings, and will be taken up later.

Alfred Stone, the delegate to National Conference on Standard Electrical Rules, made the following report:

REPORT OF THE DELEGATE TO THE NATIONAL CONFERENCE ON STANDARD ELECTRICA RULES.

"The delegate of the Institute to the National Conference on Standard Electrical Rules attended, by invitation of the architectural committee of the National Underwriters' Association, a meeting of said committee, and took part in its delibrations and the consideration of the National Electrical Code.

"It is the desire of the conference that the Institute shall elect a delegate to represent it at future meetings of the Conference, or of the electrical committee of the Underwriters' Association, for the purpose of taking part in the deliberations for the amendment of the code as occasion may require.

"There has been no expense incurred on account of the representation during the past year."

(Signed) ALFRED STONE,
Delegate to the National Conference on
Standard Electrical Rules.

OFFICERS ELECTED.

The following officers have been elected: President, Henry Van Brunt; First Vice-President, W. L. B. Jenney; Second Vice-President, J. W. McLaughlin; Secretary and Treasury, Glenn Brown; Auditor, two years, S. A. Treat; Auditor, one year, E. H. Kendall; Directors—one year, Frank Miles, T. D. Evens, Joseph C. Hornblower; two years, Robert W. Gibson, Levi T. Schofield, W. M. Poindexter; three years, George B. Post, Arthur G. Everett, W. C. Smith. Place of next meeting Pittsburg.—*Architecture and Building*.

OBITUARY.

THE architectural profession in San Francisco learned with regret of the untimely death of Mr. W. H. Lillie, one of its most promising and respected members. Mr. Lillie was but thirty-six years of age and had during his professional career acquired a most enviable position as a studious, honorable and conscientious architect. One of the last works of importance that he designed was the Masons Home for Widows and Orphans at Decoto which will ever remain a monument of his skill and judgement. The city is full of beautiful examples of his fertile mind. The obsequies were held by the order by which he was most affectionately regarded and his remains were followed to the grave by a large number of deeply grieved and devoted friends.

TRADE NOTES.

THE new Ferry Depot has just been fitted up with Clawson's Patent Revolving Ventilator with fan attachment. These ventilators receive their power from the wind and are continually acting day and night, thereby having pure fresh air in circulation all the time. They give entire satisfaction wherever used and are always open to public inspection.

ATTENTION is called to the advertisement of the Bolles Revolving Sash Company appearing for the first time in this issue. Messrs. J. E. & L. L. Kennedy have recently established agencies in this city and Los Angeles and make a fine showing of work done in the east. The sash in operation is shown in their office in this city where can also be seen their full line of overhead and mullion pulleys and various specialties in window hardware.

THE ATTENTION of our readers is called to the advertisement of N. & G. Taylor Co., Philadelphia, manufactures of the "Taylor Old Style" brand of Roofing Tin. Their trade-mark of the target and arrow is quite familiar to our readers; each sheet is stamped, or embossed, with this trade-mark; the thickness IC or IX; the brand "Old Style", and the name of the Manufacturer N. & G. Taylor Co., Philadelphia. This is done for the protection of architects, roofers, property owners, etc.

Messrs. N. & G. Taylor Co. were the originators of the idea, and were the first to put into practice the stamping of sheets of roofing tin with the name of the brand and the thickness. They have handled this kind of tin for the past sixty-eight years. It is the heaviest coated plate made, and manufactured entirely by the palm oil process. No rolls or machinery are used each sheet being dipped and re-dipped, by hand labor in open pots of metal of different degrees of temperature. It has other merits which our limited space will not allow us to describe, but which entitle the brand to the confidence of the trade. This firm can point to roofs in the old parts of Philadelphia, covered with this same kind of tin that are just as good to-day as when first put on nearly seventy years ago. They have samples in their office testifying to this fact. They have agencies in every large city from Boston to San Francisco.

To those wanting a tin roof that will last a life time, we advise their using this brand. This firm are represented in our city by Mr. Chas. J. Waterhouse, 421 Market steet.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

FLATS, Havens & Tœpke, Architects.

COUNTRY Residence, J. Murray Architect.

HOTEL GREEN, PASADENA.

HOTEL Green began in a small way, and was originally known as Hotel Webster. In 1888 it was purchased by Col. G. G. Green. He built in 1890 a brick and stone addition to the northern end of the building, which, when completed, more than doubled the capacity of the hotel. The name was changed to Hotel Green shortly after its purchase. The improvement continued. Property directly across the street was purchased and a beautiful park, with fountains, trees and flowers, was laid out and named Hotel Green Park.

When the Colonel visited Pasadena last year its marked development and growth impelled him to have constructed in the center of the park an annex, unequaled by any hotel on the Coast in point of elegance and completeness.

The two buildings are connected by a steel bridge 205 feet long, which is high enough to allow the Pasadena and Los Angeles electric cars to pass under it, trolley and all. The Annex is six stories in height, with a roof garden. The exterior is beautiful in architectural design, and lacks the tiresome similarity so frequent in large structures. The broad varanda, with its massive columns, on the eastern and

southern sides of the first floor; the sixty wrought-iron balconies, opening out from every suite of rooms in the building; the elaborate staff work, the greenery of the roof garden, the copper domes of the two southern towers and the picturesque file of the projecting roof, all combine to produce an imposing and luxurious effect.

The Moorish design is carried out in detail from top to bottom. The building is absolutely fire-proof, being constructed of steel, stone and brick. The skeleton of the structure is made of 1,460,000 pounds of steel, riveted together in such a manner that were it turned over it would still remain intact. The walls are of plaster and expanded metal, 60,000

GREEN HOTEL ANNEX, PASADENA, LOS ANGELES CO., CAL.

FREDERICK L. ROEHRIG, ARCHITECT.

square yards of the latter being used. Ninety thousand feet of expanded metal is used in the floors, which are finished in cement. Fifty tons of channel iron are used in the partitions, and 1,250,000 bricks are contained in the structure. The fact that 3000 barrels of cement were consumed demonstrates the strength of the floors and the general construction. Four hundred tons of Alpine plaster are contained in the walls.

The ceilings of all floors but the first are ten feet high, and the first is fifteen. Crossing the broad veranda one meets in the vestibule with the exquisite onyx finish. The main stairway is directly opposite the vestibule and is ten feet in width. It is made of steel, with a wrought and cast-iron railing topped with heavy oak. The steps are fourteen inches in width, with a six-inch rise, and are of marble.

There is also a stairway in the north end of the building which, with a rapid transit elevator, makes any portion o the house accessible quickly and easily.

Perhaps the most interesting portions of the building are the basement and the roof garden, two extremities. In the one may be found a double, standard-gauge bowling alley and a shooting gallery, while on the other the beauties of the whole surrounding country are at hand, to be enjoyed amid flowers, in the fresh breeze of the after-noon. In the middle of this garden the ball room, or sun parlor, is located. It is a room 60x60, entirely covered with glass. Its western side is a wall of windows, while on the east there are seven doors opening upon a pleasure balcony. The north and south ends are open to the roof garden by arched doorways, and in the northeast corner is a circular alcove for musicians. A canvas has been made to fit the northern end of the roof garden, and on special occasions, when the nights are warm, the guests may dance in the open air under the rays of the full moon. Seven flagpoles have been set at various places around the railing, and the whole garden is naturally adapted to elaborate decoration and brilliant illumination when occasion demands. In the northwest corner of the basement is the bicycle room, which is approached by a gradual decline.

A better water supply than this hotel has could hardly be wished for On the south end of the annex roof are two tanks, each of 3000 gallons capacity. Water is pumped into these by power generated at the power house. From here the water flows by gravity into two tanks on the other build-

ing, which is somewhat lower. These tanks also hold 3000 gallons each and, as they are fitted with ball values, are continually full. The water is all filtered before going into the tanks and is then filtered again when necessary. This makes a water supply for the two buildings of 12,000 gallons which is never allowed to lower.

One of the many novel conveniences of the hotel is the underground tunnel, which connects the Annex with the main building. It contains a flat car, which can rapidly transport dinner trays from the culinary department, located in the main building.

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street, at 4 p. m.

Seth Babson, Pres. — H. A. Schultz, Vice-Pres.
Oliver Everett, Sec. — John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

Theo. A. Eisen, Pres. — Arthur B. Benton, Vice-Pres.
William C. Aiken, Sec'y. — August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock p. m., the first Friday of each month, except July and August.

Jos. C. Hornblower, Pres. — Jas. G. Hill, Vice-Pres.
E. W. Dunn, Jr., Sec. — W. J. Marsh, Treas.

Association of Architects of Arizona, meetings held at Phoenix, Arizona.

D. W. Millard, Pres. — T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

BOOKS AND PERIODICALS.

The complete novel in the December issue of LIPPINCOTT'S is by Annie Eliza Brand, and has its action mainly in London. "Mrs. Russell's Sister" is a young, well-to-do and attractive widow, who takes a small house in a back street with a view to benefiting her humble neighbors; but her philanthropic efforts are apt to require masculine assistance, and all her fortitude cannot keep her lovers at a distance.

SEWERAGE AND SEWAGE DISPOSAL is the title of a new book, by Henry Robinson, on a subject matter which relates to both house and extensive land drainage. The work is confined, as far as possible, within the limit of data implied in the title, although in dealing with River Pollution and Fitration of Impure Water, the allied subjects of Water Pollution and Sewage Purification necessarily overlap. Mr. Robinson summarizes the chief conditions requiring to be complied with in the drainage of houses and in the sewering of towns. The calculations of flow in sewers are also dealt with, and the diagrams at the end of the book of discharges and velocities in oval and circular sewers will enable results to be rapidly scaled.

Considerable portion of the work is given to the best methods of profitably utilizing sewage for the fertilization of land for agricultural purposes; various schemes are discussed from the standpoints of economy, effectiveness, and practicability; copious illustrations are drawn from the experience of cities both in Europe and America. The book is published by Spon & Chamberlain, 12 Cortlandt street, New York, and is for sale by them at the published price of $4.50.

THE DAY OF VENGEANCE—This volume certainly will be valued for its extensive collection of facts and figures relating to almost every phase of social, political, financial and religious matters, as they bear upon the present situation. Nor are these dryly stated: on the contrary they are introduced in such a manner as to fascinate every reader who is at all interested in the consideration of the wonderful events of "our day." Popular edition 35 cents; in cloth binding, embossed $1.50 at all bookstores.

TESTS OF CAST-IRON COLUMNS.

A VERY important series of tests of cast-iron columns has recently been completed at Phœnixville, Pa., by the department of buildings of New York city, and from an extensive account given in *Engineering News* we make some abstracts.

Three sets of columns were tested to destruction in the hydraulic testing machine of the Phœnix Bridge Company, these being respectively 15 feet 10¼ inches long by 15 inches in diameter; 13 feet 4 inches long by 8 inches in diameter and 10 feet long by 6 inches in diameter; the thicknesses varying from 1 11-16 inches to ⅝ of an inch. In the first group were two columns taken from the "Ireland Building," which collapsed in the summer of 1895, in New York, and four similar ones cast for the purpose of the test, while the second and third groups each consisted of two columns of kinds used in regular building construction, made by well-known firms, and were fair samples, coming within the provisions of the law.

The data of the tests are tabulated in the paper referred to, and some of the salient features may be especially noted. With but two exceptions the thickness varied materially in different portions of the same column, so that in one instance the metal on one side was 1¼ inches thick, and on the other only ⅝ of an inch; and, although this was an extreme case, there was a decided irregularity of thickness, which probably affected the strength materially. All of the 15-inch columns were broken, except one, which was nearly uniform in thickness, and which remained intact at the maximum pressure of the testing machine—a load of more than 2,082-000 pounds, or more than 40,000 pounds per square inch of area. The breaking load of the others of this group varied from 25,000 to 30,000 pounds per square inch, the variations being apparently due to the presence of cinder, foundry dirt, chaplets, and blow-holes. The smaller columns were all broken with loads ranging from 22,000 to 32,000 pounds per square inch of area.

According to the building law of the city of New York, the strength of all columns and posts is to be computed by Gorden's formula, using a co-efficient of 80,000, and a factor of safety of five for cast iron. The application of Gordon's formula, under these conditions, to the columns tested shows that the 15-inch columns should have a breaking strength of 57,000 pounds per square inch, instead of which it actually ranged from 25,000 to 40,000 pounds; while for the 6-and-8-inch columns the breaking strength by the formula should be 40,000 pounds per square inch, instead of 32,000 to 22,000 pounds, as shown by the tests.

Had these colums, therefore, been loaded as heavily as the law permits, the factor of safety in some cases would have been only a little more than 2, instead of 5 as intended. Judging from the physical description given of the columns tested, this discrepancy is much more likely to be due to the defects in the castings than to the inaccuracy of the formula, and apparently a requirement for better material and more carefully made castings would raise the strength nearly, if not quite, to that indicated by computation.

An interesting feature of the paper is the description of the calibration of the Phœnixville testing machine by comparison with the Emery testing machine in the United States Arsenal at Watertown, Mass. This calibration was effected by testing a special soft-steel Phœnix column, first at Watertown and then at Phœnixville, using a roller extensimeter reading to 0,0001 inch, the conditions being reproduced as nearly as possible in the second test, and the same extensimeter being used. The result showed the gage readings of the Phœnix machine to be from 15 to 17 per cent higher than the actual values, this being due to friction of the machine and possibly to gage error. By using this correction, the tests at Phœnixville are made comparable with those at Watertown, with a possible error of about 3 per cent.

LESSONS FROM FIRE AND PANIC.

BY THE Factory Act, 1891, every new factory in which more than forty persons are employed must be provided on the stories above the ground floor with such means of escape in case of fire as can reasonably be required under the circumstance of each case. Every old factory must, after notice, be similarly provided, subject to arbitration in case of difference. The factory Act of 1895 extends these provisions to certain workshops and laundries. I think that the chief fatalities during recent years have been in factories employing less than forty, but there are other provisions for safety and for facilitating escape which may be put in force by the inspectors if the provisions above mentioned are not applicable. As to the application of these structural provisions, it has been said that if the workpeople on the upper floors are provided with means of getting to the ground floor they cease to be subject to the Act, but this view does not seem to be supported by the words of the Act, which require that such persons are to have "means of escape," and the ground floor might be on fire and not available for that purpose. These persons therefore must have means of getting clear of the building either into a street, or by arrangement on to adjoining premises, or into an open yard of ample area. In a confined yard they would be subject to the glow and heat of the fire, and this is fatal. Many of the victims at the Paris Bazaar fire died in the open yard at the rear, which was of some size, but which afforded no shelter from the fire.

The circumstances of each case which the authority or the arbitrator is to take into account appear to be such as arise from the nature and quantity of materials used, the processes employed, the danger from lifts which will communicate fire and smoke, the numbers of workmen and workwomen respectively, and the description of the premises surrounding the factory. It is sometimes argued that "the circumstances of each case" which are to be taken into consideration include such as arise from the insufficiency or inconvenience of the site, the owners system of supervision, or other matters which might have been foreseen and provided against in the selection of the site or the construction of the building, and that allowances should be made for such matters of difficulty. But there must at any rate be means of escape, and those which may be sufficient in an ordinary case may reasonably be increased and not omitted if the site, or the buildings, or the system of management are worse than common. If a factory has combustible floors and roof, the requirements may be more stringent than if it is fire-resisting throughout. But unless the plan is satisfactory, the smoke from a very small fire will quickly spread, disabling the workpeople or causing a sudden panic, whether the building is fire-resisting or not.

Some of the causes of danger are the inflammability of the stock, the way it is allowed to accumulate so that insufficient room may be left even for passages, the chance that access to staircases may be cut off by the fire, the insufficient width of the staircases, the bad arrangement of their steps, and their liability to become filled with smoke. As in theatres, there should be alternative means of escape at different extremities of the building. Two rooms may be united by a doorway, each room having its staircase at the other extremity, or two buildings having their own staircases may be united by a bridge on each floor. Generally the staircases should be concrete, secondary staircases of minor importance being of oak or teak, the treads 10 inches, the risers 7¼ inches, the width 3 feet 6 inches to 4 feet 6 inches. There should be a fire-resisting enclosure to each, with self-closing doors opening by pressure in the direction of each, but not so as to obstruct the landings. The staircase should be well ventilated and should adjoin an external wall. If that is impracticable, it should communicate with the street by a very short passage of fire-resisting construction. The roof of the staircase should be fire-resisting. If iron or other fixed sashes are to be used some should be made to open, so that persons could be rescued by means of them.

I will here allude to other means of escape which are no doubt contemplated. Iron external staircases kept clear of windows through which fire can pass may be constructed. Movable fire-escapes are to some extent recognized, for the factory inspector may require them and the magistrate may order them. But these are things properly within the duty of the tenant, and do not seem to be what the acts require of the owner, whose duty it is to put his building into a proper state structurally. Movable escapes are not satisfactory as

substitutes for structural requirements. When a new staircase was demanded in an old building the occupier pointed out that there was a movable escape ready to be let down at one of the windows. When asked to show how it worked the window was found to be fastened down, and he proposed to send for a carpenter, who was in the basement. I need not enlarge on the risks of such contrivances when used by persons not in the frequent habit of using them.

Escape downward by means of the staircase being liable to interruption by fire and smoke, other means must be made available. Very little has so far been done to provide escape by the horizontal route towards adjoining buildings or upwards through the roof. To both of these there are, however, serious objections.

The London Building Act prohibits openings through party-walls between houses in different occupations; besides which, few people would run the risk of the improper user of such convenient modes of getting from house to house without the knowledge of the owners. The late Sir Henry Bessemer showed me an ingenious arrangement by which this last objection was sought to be removed. An opening only 16 inches wide by 3 feet 6 inches high was made in the party-wall at a foot above the floor level. On each side was a very strong iron door and frame, on the inner side of which was a pair of knockers. On an alarm of fire in either house the inmates would open their own door, and ply the knockers on that of the neighbor, who might be expected to come quickly to the rescue. The outside balcony is a much better arrangement, and if it could be generally adopted on each story, or only for alternative stories, there would be in most cases reasonable facilities for rescue. But the balcony, though a beautiful architectural feature, is almost unused in this country. It might cause apprehension of improper access from house to house or from room to room. I have, however, lived for many years in a district where every house has a spacious balcony above the ground story, and I have not heard of this objection. There is an easy means of passing from the window of one house to the nearest window of the adjoining house by fixing a short length of balcony between them crossing the end of the party-wall.

But the best means of escape after the staircase is by way of the roof, a good flight of stairs being provided to the roof door, which should have an automatic fastening. The Cripplegate fire happened to originate in one of the manufacturing warehouses which was first dealt with by the London County Council under the Factory Act of 1891. The two upper stories were occupied by seventy or eighty workgirls, and the owner willingly put a proper door to lead on to the roof. By this route he and they got away, and without it they must all have perished. But easy as it was, there was considerable difficulty in getting the girls out in the few minutes available, some having fainted or become uncontrollable in their excitement. As the workwomen are usually accommodated, often by hundreds, on top stories, this is a useful lesson in construction of means of escape.

I do not suppose that roof doors will be willingly adopted where valuable stocks are kept, but in a district of warehouses where the roofs were properly adapted for escape there might be a watch kept on the roof against thieves and the outbreak of fire.

The construction and arrangement of public buildings, that is, places of worship, schools, hospitals, workhouses, theatres, halls, exhibition room, and other public places of assembly in London, are in certain respects regulated by the London Building Act, 1894. The general construction must be to the approval of the district surveyor, subject to a tribunal of appeal, but the Act requires that the floors of lobbies, corridors, passages and landings, and the flights of stairs shall be of fire-resisting material. Besides this the dimensions of passages, staircases, and exits of new churches, chapels, meeting houses, public halls, lecture rooms, exhibition rooms, or places of assembly are laid down in the Act. Staircases must be carried and enclosed by nine inch walls, and with the corridors and passages shall be not less than four feet six inches wide, but if not more than two hundred persons are accommodated this is reduced to three feet six inches. If for more than four hundred persons an addition of six inches for every additional hundred is to be made up to a maximum of nine feet and when the width is over six feet there is to be a dividing hand-rail. If two staircases or passages are put instead of one, each must be of two-thirds the above dimensions, but not less than three feet six inches. And if one portion of the public is accommodated over another portion they must have a separate exit. All doors and barriers must open outwards, and no outside locks or bolts are to be fixed.

As regards public buildings in general these are new provisions. They are a somewhat mild adaption of the much more stringent regulations that have long been applied to theatres and music-halls, and they were very much required.

I was once asked by a member of a Parliamentary Committee who desired to ridicule our theatre regulations why we did not seek to apply them to churches, and could only suggest the comparatively infrequency of accidents in such places. But the reason was inadequate and Parliament has since recognized this in the above provisions. There are many more accidents in places of worship than is commonly supposed, and the most serious have happened in such places. The crowds are often more dense, and precautions are hardly thought of. One, or perhaps two doors are thought enough for many hundreds of people. The organ and heating apparatus and vestry are in dangerous proximity, artificial light and decoration are on the increase. A senseless panic ensues on the least alarm.

To go back rather a long way, in 1120 the monastic church of Vezelay, in France, was burnt, with 1127 men and women. And other similar fatalities are found in old records. Some seventy years ago, at a festival, when the cathedral of a South American city was crowded with the whole female population, the elaborate decorations which thoughtless people always add on festal occasions, took fire, and 2000 perished, hardly any escaping. A few months ago some decorations in Pisa Cathedral took fire, and in a panic twelve persons were crushed to death and twenty injured. A few weeks ago, fifty-four people were killed and eighty injured at a fire in a church in Russia. A few days ago, the organ and gallery of a chapel in Hull were blazing when the Sunday morning congregation assembled. If this outbreak had been delayed for half an hour we might have had an object lesson in panic. I mention these matters because the architect will feel that he ought not to provide anything less than the moderate securities demanded by the London Building Act; and if one or two additional doors are required, they are at all times a convenience to a crowded congregation. If the precautions above mentioned are required in a new building, I am unable to see why they should not within a reasonable time be demanded in old buildings as well.

To be Continued.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in one package, including all bolts and screws necessary.

See a full size working model at our store.

BUILDING NEWS.

LOS ANGELES

The board of trustees of the Los Angeles branch have made its biennial report to Gov. Budd for incorporation in his next message to the legislature. The board ordered contracts let for the construction of asphalt walks and the laying out of a portion of a portion of the grounds for gardens for the use of the botany class.

Among the improvements recommended is $30,000 for improvements, consisting of moving the gymnasium building two floors, one for a manual training work room and one for enlarging the training school and $5000 for improvements in the present training school quarters. For the library, $10,000 is asked. This will give a building 40x48 feet and will be ample for the students as well as the books.

For necessary repairs and painting $1500 is asked; and for furniture and apparatus $4000. The total amount necessary for the support of the school, besides the new buildings mentioned is $124,5000.

Plans have been prepared for Whiting Thompson, for a two-story 8-room frame residence to be built on Orange street near Union venue. The work on the building is being done by day's work.

Architect R. B. Young has prepared plans for Jas. B. Lankershim, for a warehouse building, 100x100 feet, two stories and basement, as an addition to the factory of Bishop & Co; at Seventh and Alameda street and will be ready for bids next Monday.

Architects Howard & Train are preparing plans for Mr Williams, an attorney in the Laughlin building, for a one-story frame residence of seven rooms, to be built on Burlington avenue near Eight streets; the inside finish of the principal rooms will be in oak balance in Oregon pine.

PASADENA

Architect R. B. Young has let the contract for the excavating for the new Catholic church to J. H. Dovey; it is expected that bids for the structure will be opened soon.

John M. Smith of Montana has purchased 150 feet frontage on West Colorado street between Terrace drive and Orange Grove avenue. It is the intention of the present owner to improve the property with a handsome residence.

RIVERSIDE

J. W. Babcock will begin at once the erection of a $1500 house on the ten acres on the corner of Indiana avenue and Jefferson street.

SANTA ANA

Bids for the construction of the internal sewer system have been opened last week. Fourteen firms competed; the lowest being the Williams, Belcher Co. of San Francisco for $86,844.44.

For Sanitary Reasons

You Should Specify the

Brown Brothers' Cold Drawn Seamless Copper House Range Boiler.

The smooth copper surface is heavily tinned inside. This absolutely insures against corrosion or rusting of any kind and affords no rusting place for sediment. You alway get

Clean Hot Water

own Boilers are made of two pieces of cold drawn copper, united under great hydraulic pressure, so that they are practically one piece. No seams nor rivets, means freedom from leaks. The inside spiral rib guarantees against collapse. Ordinary weight boilers stand a pressure of 150 lbs. to the square inch; extra heavy, 200 lbs.

Boiler Booklets sent on request.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

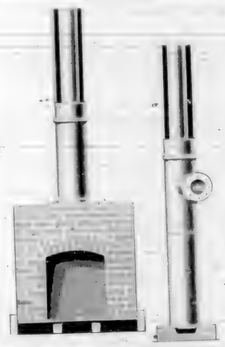
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET, SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

☞ Send for illustrated circular.

The California Architect, $3.00 Per Year.

UNFAIR COMPETITION.

Our recent announcement that inferior goods had been sold and billed on the Coast as our goods, and that our trademark numbers had been counterfeited, has disclosed an even greater extent of these practices than we had supposed to exist. To make the resulting damage to the reputation of our goods as small as possible and to protect our would-be patrons we repeat:

All our catalogue goods, except those listed by us as manufactured by others are stamped with our name "Keuffel & Esser Co." or our initials "K. & E. Co." and where there is room for it, with our trademark trademarks or . **We never stamp our goods with catalogue** Our German drawing instruments bear only the **numbers only,** and goods so stamped are therefore not ours. All our goods are fully warranted to conform to the description we give of them in our catalogue and to be of the quality and grade specified. We make some lines of cheaper goods for the jobbing trade, but they differ from our catalogue goods in quality and appearance. These inferior goods are not stamped with any of our trade marks. Our catalogue goods are not furnished to any dealer or agent without our complete stamp as described above, and any claim that we furnish our catalogue goods by special arrangement without our stamp is therefore an attempt to deceive. Our special papers in rolls or sheets

Duplex Universal Anvil Lacagon Normal

are watermarked or stamped along the edge with their name. Any claim that our papers are furnished by us in bulk without these names or that these papers have been obtained otherwise than through us, are absolutely false.

We will thankfully accept any information bearing on the counterfeiting of our trademark numbers or the palming off of other goods as ours.

VERY RESPECTFULLY,
KEUFFEL & ESSER CO.,

The Yale & Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key, afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," the range of products and grades is such as to meet conditions where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

THE CALIFORNIA ARCHITECT AND BUILDING NEWS extends the seasons warmest greetings to its patrons and friends The efforts to render this publication worthy of the profession and commensurate with the patronage it enjoys is every day bearing fruit. The words of appreciation expressed by contemporaries and individuals are in the highest degree cheering. It encourages attempts at improvement and increases the determination to equal, if not surpass, the very best publications that issue from older communities. It is believed that a new era is opening for San Francisco and the coast, one that will bring added prosperity to this lavishly endowed section of the country and open out a period of advancement and wealth in which the architectural profession and builders generally will, of necessity, have a great share. It will be the continued aim of the publisher, as it has always been, to support actively the interests to which it is devoted by every means in its power. Its loyalty to San Francisco and the coast and to every interest that aids to bring new developments and increased prosperity throughout the state is known and appreciated. No assurance is needed of continued effort. THE CALIFORNIA ARCHITECT AND BUILDING NEWS is accepted all over the world as the representative and exponent of the builders profession of California. It reaches every architect west of the Rocky mountains and its value as a means of communication between the manufacturer and the especial interests of which it is the organ is attested by its increased advertising patronage and swelling circulation. To all our friends, east and west, we tender congratulations and a sincere hope that the future will prove a prosperous season to one and all.

LAW LICENSING ARCHITECTS.

THE coming session of the State legislature gives an opportunity for a renewed attempt to be made to secure the enactment of a statute compelling all architects to take out licenses and authorizing builders to employ only such architects as have duly complied with the law. The sentiment toward such a statue is growing in the east and in every settled community the necessity of such a law is becoming more and more manifest. Illinois has a model statue on this subject, passed soon after the Chicago fire had demonstrated a necessity for such action on the part of those interested in the welfare and protection of communities. The country is in the throes of a tremendous expansion. Building construction has advanced so rapidly that the methods of ten years ago are almost obsolete. The demands of the present require a nearer approach to fire-proof standards then ever before and greater attention to scientific details. The architect of today to be successful is necessarily compelled to master these details and to expend more time in acquiring the education that fits him for the excessive responsibilities demanded. The law exacts heavy penalties for those who presume to trifle with the health of communities and practice medicine without the license of competent authority and it appears to many that architects as the guardians of the safety of the people should be protected from the competition of every amateur who thinks himself sufficiently gifted to plan a dwelling.

FROM FORT POINT TO THE CLIFF.

HIS HONOR, Mayor Phelan, at the dinner to the visiting architects at the Bohemian Club a few evenings ago, surprised and delighted the gentlemen present by an announcement that Mrs. Hearst had authorized the formation of a committee to have in charge and to formulate some general plan for the adornment of San Francisco, with special attention to a new system of sewerage, tree planting, laying out boulevards and the like, the design being to render the city attractive to the outward senses and more delightful as a place of residence. It would be difficult to imagine a more opportune or useful suggestion or one more in line with the spirit of the age. San Francisco has always relied too much upon its fine situation and impressive surroundings to give sufficient attention to artificial adornment but it is learning and now one of the missions of Golden Gate Park is at least being manifested. The park has demonstrated how the most unpromising conditions may be made into a scene of beauty and enchantment by the expenditure of a moderate amount of money and the employment of competent landscapeists. What has been done in this one location may be accomplished in lesser degree any where else in the city. Such an example of floral beauty and improvement is possible no matter how small the area available for the purpose may be. Improvement of home lots is thus stimulated and rivalry between neighbors becomes acute. The appearance of the streets is also vastly enhanced and at the same time mor valuable for building purposes and thus the tendency to remain a resident rather than to seek the enticements of suburban localities is lessened. Architects are intensely interested in this question of municipal improvement for upon it rests the question, in a large measure, of the rapidity of future expansion. This committee, which has been most judiciously selected, will, ere long, be seeking the assistance of those who can help by suggestion or otherwise. In the matter of laying out new boulevards much can be said. The present is the time to begin. Land is cheaper then it will ever be again and vacant properties on the line of these proposed new roadways may be acquired at low prices. The time is especially opportune, as the government is disposed to aid in the improvement on account of the future importance of San Francisco as a center of military operations. All of the projected boulevards connect with those of the Presidio, for the reason that these are already constructed and furthermore because of the wonderful natural attractions of the reservation. Practically a boulevard extends from Market street by the way of Van Ness Avenue to Fort Mason and thence along Lombard street to the Presidio where it extends to Fort Point as well as to Pacific Avenue. Lombard street should be widened to the dimensions of Van Ness Avenue at once. The government would assist and by this means several miles of perfect drives would be obtained at very slight expense. The extension of a boulevard from Fort Point to the Cliff House is perfectly feasible though an expensive project. Those who have inspected the Riverside drive along the Hudson at New York understand the enhusiasm with which that splendid improvement is regarded. There is an opportunity for not only exceeding the splendors of Riverside but of constructing one that will be unequaled in the whole world by following the line of the coast from Fort Point to Point Lobos, a distance of perhaps four miles. Could any thing finer be possible. Imagine a driveway as wide as Van Ness Avenue stretching the entire distance, adorned with trees and shrubbery, with facilities for pedestrians, affording at every step a splendid prospect of one of the great views of the world. The entire distance from Fort Point to the Cliff would be one long panorama of scenes of unsurpassable beauty. The expense of constructing a roadway along the Cliff would be great but would be more then offset by the advance in the property along its course which would soon be appropriated for home sites. The roadway, moreover, would give the government access to the fortifications which in time will be erected at the entrance to the bay and it would, without doubt, liberally assist by appropriation the carrying out of such a design. No professional instinct is necessary to the understanding of the result of the construction of a shoreway as suggested. The immediate consequence would be the appropriatino of all the land frouting on the bay shore and the construction of palatial homes each with terraced lawns extending down to the waters edge. Neither would the expense be beyond the ability of the community. No difficulty whatever, in an engineering sense, exists that would prevent the execution of such a design. It would be simply a question of grading and the disposition of the material.

A shoreway drive along this route would form a connecting link between the center of of population and the grand ocean drive way that is partially constructed along the western border of the city and would give access to the park from the west besides running through a territory which street car lines would never invade or obstruct. Such a driveway, which is suggested only in general terms, would also add greatly to the beauty of the harbor entrance and prove an impressive exhibition of the power and wealth of the city to every one who enters through the Golden Gate by the pathway of the sea.

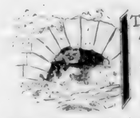
THE COMING OF THE NEW SCHOOL.

ONE of the signs of the times is the unexpressed longing or aspiration for a new school of architecture that will be American in its distinctive character and national in its type. This hope is not confined to the architectural profession. Heretofore this nation has had to be content to follow the ancient schools. Every civilization but our own has furnished to the world some conceptions or types that were purely characteristic and original and reached their highest perfection or development just before these nations began to retrograde or decline. Perhaps the luxuriance reached in matters pertaining to art was an indication that the fruit was ripe and that the worm of decay was already at work. Examples of such coincidences are too numerous not to have been remarked by philosophical observers and some have accepted as an axiom that extreme development of the purely inellectual arts is a positive indication of a lack of national strength and of ultimate effeminacy. If such theories are well founded the American nation has a long life before it judging from the imperfect development of the arts and our utter dependence upon Europe for every thing to art pertaining.

So far America has contributed nothing but the tall building in return for all the architectural contributions it has received from older nations. The tall building is distinctive only as an example of audacity and new methods of construction and is confessedly inartistic and ugly but at the same time great. The painful sensation that srrikes the American traveler on finding that all the architectural wonders of his own land are merely repetitions of a type to be met with in every considerable city of Europe is distressing as it compels a confession of inferiority. Regrets at the dependence and lack of invention of the American architect will aries unbidden for even the details of his work as we learn by the examination of a certain carefully edited work, copiously illustrated on "Architectural Details" published by a master of the art and filled with foreign studies of windows, doors, arches, gargoyles, minarets and little tid bits, especially for the use of American architects. The Apostle of the new school has not yet deigned to indicate a sign of his early appearance. The faithful are longing for the day of the prophets arrival and in the meantime have to be content to follow in the old beaten tracks. It is said that all the successful plans of the Hearst competition for the California University are of the French school, and if carried out on these lines a type will be established in California from which the state will not be emancipated for a hundred years. The fact is ominous for the rise of a new school of architecture on the western coast and is a lasting witness to the lack of originality possessed by present day architects.

It would appear to a non-professional that the day for the classic, Romanesque, Italian, Gothic and other styles which had their rise centuries ago and which survive only on account of inability to invent better ones, is past. Sublime as some of the instances of these types existing are, a complaint of repetition and monotony in the building of later days is made on good grounds. The nations which are the great builders are so rich and their resources so vast that ordinary plans of construction are insufficient as an expression of the spirit of the age. An era of construction is about to begin in our own land that will dwarf all early efforts. The industrial future of the country is to surpass the most sanquine expectations of the greatest optimist and the growth of wealth will be evidenced by the size, number and grandeur of the builders creations. It may be that the new school that is to arise will find its germs in California where the Mission or Morosco types has numerous examples. It would not be surprising if the oldest architectural methods and character should supply the suggestions for a distinct school for the newest and greatest of nations.

OUR FOREIGN VISITORS.



IT has been flattering to the publisher of THE CALIFORNIA ARCHITECT AND BUILDING NEWS to learn that even in the distant capitals of Europe this publication is accepted as the ultimate authority in all matters relating to architecture and building in this part of the world. Nearly all of the eminent architects who are visiting San Francisco in the interests of the great University competition, from Paris, Vienna, London and Dresden, have done us the honor of calling and taking advantage of our facilities for information which has been most freely tendered. The universal expression from the visitors is of admiration and astonishment at the great progress made by San Francico in its brief existence. The people, the country, the buildings, all are away beyond their anticipations. "Almost like Paris," remarked a gentlemen from La Belle, France. The impression left by the visitors has been most agreeable. May they all win.

MORE RESIDENCE SPACE.

WHEN the late Adolph Sutro set about making the Heights at the Cliff the attractive spot that it now is, his purpose was not altogether selfish. He had acquired enormous tracts of sand covered real estate in that vicinity and, undoubtedly, hoped to influence its advance in value by demonstrating that these bleak, barren and exposed acres were capable of high cultivation and would richly repay the care

and expense necessary to demonstrate that fact. Mr Sutro, notwithstanding his capacity to drive hard bargins was a good deal of an idealist which was proved by his fondness for art and the remarkable judgement he displayed in the choice and selection of his art treasures. The Heights which he developed into a show place, surpassed by very few in the world, is a demonstration of his refined taste and cultivated mind. He appreciated the most magnificent of all Pacific Ocean views and foresaw that the whole plateau bounded by the harbor entrance almost to Golden Gate Park would eventually be covered with the homes of that rich and cultivated class which in the future will be included in the population of San Francisco. It is a matter of great surprise that in planing this city some one did not suggest a series of grand boulevards. In only one instance is there a residence street of more than ordinary width, Van Ness Avenue. Possibly those early engineers did not anticipate the rapid growth of the city or else there were no mayors like Sutro or Phelan to suggest that in the laying out of a great city only utilitarian purposes were to be considered. San Francisco seems to have been laid out on a principle that secured the largest number of building lots in the smallest possible area. At all events the rich who build fine homes and spend most money in adorning them were not considered when the present plans for arrangement of the streets were adopted. The spectacle is actually afforded in this city of no place where the rich can live and be surrounded on all sides by sympathetic and congenial companionship. What is meant by this some what surprising statement is that in all San Francisco there is no portion of it exclusively designed for the wealthy. New York has its Fifth Avenue, Boston, its Back Bay, Cleveland its Euclid Avenue but San Francisco nothing but Van Ness Avenue which in a few years will be monopolized by business and given up to commercial pursuits. In the not distant future residence will be banished from the entire section east of Van Ness Avenue. The beautiful streets running west are not by any means overlooked in this controversy but there is hardly one of these that are not almost ruined by their extraordinary and impossible grades.

What is now needed is a section devoted exclusively to residence for the opulent, where the wealthy can make such display as suits them by building expensive homes and laying out attractive grounds, where broad avenues can be devoted to public drives and street cars do not invade, in fact a Boston Back Bay in which the rich may indulge in their fancies and the public at large be benefitted by the example. There is plenty of space in the north west section of the municipality to create just such an ideal. The ground is level and no where is there to be found grades not of the mildest character. The views in every direction are superb and easy access can be gained to the park or to the sea. The Sutro lands are in the market at reasonable prices and land is no where in this section extravagantly high. Let some enthusiastic and energetic real estate dealer take hold of the idea, let capital absorb the lands necessary for this purpose and the reward of the enterprise will be great. The wealthy would quickly respond, and a new section, built up in splendid homes, adorned with smooth lawns and rich in foliage would soon become a fact. Let street cars be forever banished from the broad, level roadways and only structures worthy of the place be allowed. Such a residence section would attract and in a short time its enhanced beauty would become the boast of the western half of the continent.

PROTECTION OF IRON AND STEEL AGAINST FIRE.

It is just as impossible, under prevailing conditions, to construct absolutely fire-proof buildings as it is to prevent the occurrence of conflagrations altogether. What can be and should be demanded of our architects and builders, however, is that their constructions shall be made fire resisting to such a degree that the efforts of the Fire and Police Departments towards life and property saving have reasonable chance and time for success. In residences and busine s edifices, where structural iron or steel is necessarily employed, and where the danger of a fire gaining headway is increased by the more or less inflammable contents, iron and steel have proved most dangerous building materials. At the great conflagrations of the warehouses in Hamburg, Germany, 1894-5, and of the Borsig Mill in 1898, it became evident that a fire lasting but a comparatively short time would alsolutely demolish the strength of unprotected iron columns. The exposure to heat of a very small portion of the surface of a support of this material is sufficient to promptly destroy the whole structure depending on same. The power of resistance of iron diminishes very rapidly at increasing temperatures.

Calling the tensile strength of iron at 20° C. 53,400 lbs. to the square inch, 100 per cent, it is at

150° C.	97 per cent	
200° "	95 "	
250° "	93 "	melting point of Tin.
300° "	90 "	
350° "	85 "	Lead melts at 330
400° "	73 "	melting point of Zinc
450° "	61 "	
500° "	38 "	melting-point of Magnesium
550° "	23 "	at this point iron appears red-hot in darkness
600° "	19 "	
700° "	16 "	dark red
800° "	11 "	dark cherry red
900° "	6 "	cherry red
1000° "	4 "	light cherry red

A limited space or portion of structural iron can readily become red-hot by the flames striking it. Even if the danger be lessened by heavy construction, these conflagrations have proved that increasing the weight five fold does not avert collapse of the structure at 700° C. Red-hot cast iron also cracks at the joints easily, and at 1100° it begins to melt. Iron being a good conductor, renders it all the more dangerous, and so does the great expansion of the material in heat, causing disastrous bending. When water is applied rapid contraction ensues; hastening collapse. Moderate heat suffices to destroy arches or vaults resting on iron or steel.

The conflagration of the Borsig Mill showed the most fanciful bending and twisting of iron and steel columns, girders and supports, and many of them must have been as soft as dough. The building was totally dastroyed.

Wood has proved greater power of resistance at these conflagrations than could be expected. Constructions of wood at time of fire can be fairly judged by inspection, enabling the fire department to estimate the probable time of collapse. At these conflagrations iron and steel constructions have however, nearly always collapsed unexpectedly, rendering the work of the department very dangerous.

Structural iron and steel should therefore be protected by fireproof covering. There are numerous materials offered for this purpose, but when tried they have generally been exposed to moderate heat (under 1100° C.) only, and then only for about an hour. Fires in warehouses, manufactories, etc., however, generally lasts for hours. Of a fireproof material it must be expected:

1. That it does not burn itself.
2. That its strength must not suffer materially when exposed to heat for a considerable time.
3. It must be a sufficiently poor conductor of heat, so as to protect structural iron or steel for hours from deformation.

Among the newer materials, the Asbestos Cement, invented by Engineer Kuhlewein, has after many severe tests, extending over hours, been conceded the first place as the most valuable fire-proofing material extant, and its use has consequently found rapid extension. This Asbestos Cement is fire and smokeproof, a very poor conductor of heat, weatherproof, and deadens the sound. Ceilings, walls, floors, doors are made of the same. It is used in the construction of hot-air conduits, elevator shafts, for the covering of stair cases (lower side) of columns, girders, supports, etc., the filling of fireproof safes, by the Imperial German Navy for isolation of magazines on board ship, etc.

The Hamburg Fire Department made tests showing that the Asbestos Cement Kuhlewein in the form of a covering of 1,6 inches in thickness protected a cast iron column against a temperature of 1400° C. for over four and one-half hours. The Altona Fire department made tests in which cast iron girders and columns with Asbestos Cement covering stood a temperature of 1000° 1200° C. for six hours without bending or deformation of any kind.

The Asbestos Cement Kuhlewein is a powder like Portland Cement, and is used like the latter. It sets when mixed with water. No sand is used. Any efficient laborer can apply it without difficulty. The price is moderate. Thickness of Asbestos Cement covering required is from 0.8 1.6 inches say on an average 1.2 inches. No air space is left between the metal and the Cement covering.

The Chief of the Fire Department in Bremen, Mr. Dittman, certifies that Asbestos Cement Kuhlewein is by far the most efficient material known so far for fireproofing.

The Fire Marshal of San Francisco, Mr. Chas. Towe, states as follows:

"A short time ago you gave me a sample of Kuhlewein's Asbestos Cement. I mixed it with water and spread it on a sheet of paper, one-eight of an inch thick, letting it dry over night only, I then placed it over a Primus oil stove which gives a great heat under an air pressure, it was over the fire for thirty minutes, and the paper which was on top of the Cement, was not discolored, it was long enough to satisfy me that it is the best fireproofing I ever saw or experimented with, and I hope it may be universally used as plaster on partitions, walls and ceilings, thus making a frame structure slow burning, confining a fire in the room in which it may start.

"As a covering for columns and iron girders, it would surely cause them to be fire resisting, keeping the heat and water from coming in contact with them in case of fire, thus causing them to stand and retain the heft they may be carrying and to a great extent insure the safety of the building from fire. It is a wonderful fire resisting Cement."

NEW YORK BUILDING LAWS.

In several recent issues of the *Engineering Record* the weak points in the New York building law are pointed out, and the subject illustrates very well how the growth of a city and the introduction of new methods may render many points in once adequate ordinances quite obsolete or insufficient. When the existing building laws were enacted, the system of conducting business buildings was altogether different from that now in use. The limit of height was five to six stories; light brick walls, timber columns and floors, and moderate loads were the rule; the moderate tall building, with its steel skeleton and deep foundations, was unknown, and any attempt to regulate the practice in modern building work by rules based upon the older conditions must necessarily be defective.

It is doubtless true that the modern great buildings of New York are well designed and properly built, not because the ordinances have required proper work, but because the engineers and architects in charge have attended to it on their own and their client's account. This, however, is not a good state of affairs, and should not be depended upon.

"Good architects, good engineers and good builders have in many cases done what the building ordinance has failed to require them to do; but that is not enough. Well-intentioned men are sometimes not well qualified to do those things which they may desire to do, and such things as indifferent and careless, not to say unscrupulous, building are not unknown."

Most of the criticisms of the building ordinance of New York are naturally made on the score of omission—a thing to be expected when the practice has outgown the legislation—and a few of these defective features are worthy of mention. In the question of the quality of materials employed, vague terms, such as "the best material, made in the best manner," should be replaced by specific terms of precise, legal, and scientific meaning, about which no difference of opinion could exist. The methods of testing and describing materials of construction are well enough known to permit of accurate specification, and materials of lower grades could be clearly specified as permissible for those purposes for which they are fitted, and no hardship wrought and no danger incurred. The present law includes some attempts to use scientific formulas for certain limited purposes, but so indefinitely as to permit almost any proportions to be deduced.

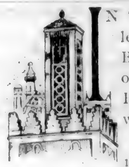
Working stresses permitted on iron, steel, masonry, timbers, etc., need careful revision and extension, in accordance with the advance of knowledge concerning the behavior of the materials and the changed conditions under which they are used. Some valuable materials, which are now practically excluded, because of the omission to provide load factors, should be included, and altogether a much broader scope for materials to be used is desirable, and, with proper provision for test requirements, would be perfectly safe.

These are but a few of the important points which have been advanced to show the weak points of the present antiquated law, and the urgent need for proper revision. That this revision should be made with the assistance and advice of competent engineering specialists is evident.

"The work of revision of the structural features of the building law should be put into the hands of a small committee of experts in structural matters whose broad experience in engineering and architecture, and whose character as reasonable men, would ensure a comprehensive, safe, and thorough treatment of every feature of the whole matter, so that a building law truly worthy of the greater New York would be secured."

THE NEW POODLE DOG RESTAURANT BUILDING.

WM. MOOSER & SON, ARCHITECTS.



IN THE past few years it has been the privilege of the CALIFORNIA ARCHITECT AND BUILDING NEWS to chronicle the erection of more buildings of the first class in San Francisco then in all the previous years in which this publication has been issued.

Each of these great structures have marked a distinctive advance upon its predecessor and denoted the friendly rivalry existing among architects and builders as to which should produce the most perfect example of architecture of to-day's methods. The property owner has been stimulated into greater expenditure and the result is that the streets of San Francisco have been highly improved in appearance and the city supplied with structures that have no superiors in any of the great mercantile centers of this country.

A SUITE ON THE THIRD FLOOR.

The latest edifice to which particular attention is called and in the construction of which the most advanced ideas have been embodied, combined with the utilization of all the arts capable of employment in the creation of a harmonious whole, is the conception of Wm. Mooser who is one of the rising local architects. It is the new building of the Poodle Dog restaurant, at the corner of Mason and Eddy streets, the final home of an institution which for thirty years, in less sumptuous quarters, has been the scene of many gastronomic triumphs of the past.

The lot upon which the new restaurant stands is 44x85 feet in dimensions. The foundations are of solid concrete laid so massively that no disturbance, however great, can have the slightest effect upon the stability of the lofty walls of the superstructure which surmounts them, indeed, so compact are they that if it had been desirable to double the present height of the building, these solid concrete foundations, made of the famous Josson cement, would have withstood the great additional pressure without a strain.

The foundation of a structure is a positive indication of the character of the building above it and the solidity and massiveness of those that support this lofty edifice, corresponds with the immovable and stable building that is built to endure for a hundred years to come.

Upon the shoulders of Mr. G. Moore rested the entire responsibility of building adequate foundations as well as the task of plastering the entire structure, a difficult undertaking as the results of all the art effects depends largely upon the smoothness and grain of the surface upon which they are to be placed. Experts pronounce the work of Mr. Moore in this structure as beyond criticism.

The style of the building is Italian Renaissance and is an almost perfect embodiment of this difficult school. The striking symetry and exquisite proportions of the exterio are remarkable. Fortunately, the dimensions of the land available afforded ample space for a high structure and unlike many others, built upon narrow lots, the appearance of too great slenderness is entirely wanting here.

The beautiful simplicity and refinement of the exterior, adds, rather than detracts from the impression of dignity which at once strikes the studious observer.

This effect would not have been possible but for the judicious choice of material for the exterior which is of Roman brick and cream colored terra cotta, supplied by N. Clark & Sons from their great pottery works in Alameda. The critic who advocates greater variety of color that may be judiciously employed as an effective adjunct of street architecture should carefully note the soft, warm tone imparted by the beautiful tint of the terra cotta covering in this instance. It is most pleasing to the outward senses but has a painful effect, by comparison on the neighboring structures.

It is without astonishment therefore to learn of the enormous increase in the employment of terra cotta for exterior adornment in all pretentious buildings. Its clear cut effects

and the admirable mouldings of this material, which are to be observed at all the salient points of the structure, are infinitely superior to the old fashioned and inaccurate stone carvings hitherto employed. Terra cotta mouldings are always exact duplicates. Each is as perfect as are all the others. The exquisite perfection of the terra cotta employed in this building is due as much to the fine mechanical devices which Messrs. Clark & Sons control, as to the superior quality of clay used which comes from Ione, a place among the foot hills of the Sacramento Valley.

The smoothness and finish of the outer walls of the new structure is to be credited to the superior workmanship of the contractor to whom was intrusted this important portion of the work Mr. D. J. Brennan.

Experts acknowledg that the walls of the new restaurant exhibit the most perfect specimen of brick laying to be found west of the Missouri River.

The building, like all others of its type, has an inner frame of steel around which the exterior walls of the structure arise. The solidity and endurance of the edifice is assured by the quality of the workmanship and material employed in the construction of this steel frame. Properly constructed such building is proof against earthquake, fire or decay. The Western Iron Works were awarded this part of the work and have fully justified their past reputation for conscientious fulfillment of all their undertakings by the superior manner in which the steel work, including fire escapes, of the building have been performed.

In this connection attention is particularly called to the efficient work of the Vulcan Iron Works which supplied the cast iron columns and other work of the same character and whose admirable and precise fulfillment of their obligations won the encomiums of the exacting architect.

Passing to the interior of the new building it is here proper to observe that no considerations of economy or contracted financial resources influenced or controlled, in the slightest, the choice of the work to be accomplished or which firms should perform it. In this matter the architect had a free hand. His instructions where "to have the best of everything" and this explains why so perfect and harmonious results were every where achieved.

The completed structure, as it now stands, is an object lesson for all prospective builders, either of mansion, public or ecclesiastical, on account of the absolute perfection in finish as well as the appropriate selection of every detail, usually considered as subordinate to the great general plan, but which goes so far towards arriving at artistic harmony and contributing so effectually to the confort and satisfaction of the individual.

In any description of the newly erected great building in this city, the Western Expanded Metal and Fire Proofing Company is always remarked. The part in which this great corporation is deservedly prominent in all these great structures while not always apparent to the naked eye, is to apply their wonderful inventions in the plan of erecting an absolutely perfect structure and giving to the edifice that strength and durability combined with fire proof construction which is accomplished by a system of concrete arches and partitions and metal lathing. No great building is complete without the application of this company's principles of construction by which space is economised and perfect results attained.

The plaster used in the Poodle Dog building from banquet hall on the top floor to the basement below is that famous brand known everywhere as the Alpine Plaster of which Smith & Young are the agents.

In referring to the workers who have so distinguished themselves on the new Poodle Dog building, Mr. J. P. Donovan, connected with the Western Expanded Metal and Fire Proofing Company in a responsible capacity should not be forgotten.

The artistic possibilities of steel, iron, copper and brass is conspicuous throughout and is lavishly displayed in every part of the building. The balustrades and grill work are exquisite in design and execution. The San Francisco Novelty Works are famous for their great accomplishments but they have never succeeded in so thoroughly establishing their fame, beyond any or all competition, as by the elegant and truly artistic work they have performed on this structure. Both exterior and interior is thus adorned. In the perfection of every detail this work is surprisingly complete.

A description of one of the eighteen suites into which the third, fourth and fifth floors are divided involves that of the

BATH ROOM ADJOINING EACH SUITE.

entire number. Each one is furnished in a different wood of its natural color, and each suite is furnished in royally lavish and elegant style, especially so in the appurtenances of the bath, every suite being provided on the most liberal scale with tubs, sitz and shower baths, closets, etc., and everythiug else that can contribute to comfort and cleanliness. The utmost care and research was expended in bringing this especial feature of the establishment to the highest degree of perfection and efficiency, and in the active competition for the distinction of furnishing so great a work as this the very finest apparatus and material of the country was represented. Messrs. George H. Tay & Co. were the fortunate ones, the perfection of their goods, their artistic design and their unapproachable quality was so well understood that other competitors were nowhere. The porcelain tubs aud sitz baths are

models of elegance and convenience, and they are all fitted with the most perfect devices for easy and efficient management. Messrs. George H. Tay & Co., it must be understood, supplied from their fine establishment all plumbing goods used in the great building, and so satisfactory to all concerned as to win most enthusiastic encomiums. The perfection of the latest developments of sanitary science is here demonstrated.

It should be noticed also that all the water closets, of which an unusual number were required, are of the famous "Royal" brand of manufacture supplied by The John Douglass Co.

However perfect the appliances may be, in this important feature of all construction, they are of no avail unless worked by a master hand. The task of the plumber in this building was one of the most difficult ever undertaken, and required the exercise of the most scientific attainments. Besides being a work of uncommon magnitude it involved the application

BANQUET HALL.

of certain improvements designed for the attainment of absolute perfection. To Mr. Joseph Butler this task was given, and how magnificently he fulfilled his contract the work emphatically demonstrates. In this work, Mr. Butler has surpassed himself, though in hundreds of other instances he has proved how thoroughly competent in handling this branch of household science he is.

The bath rooms, which are all exhibitions of remarkable attainments in the art of plumbing, are distinguished also; and no one can enter one without being struck by the beauty of the wall tiling which, in each, cover fully one-half the surface and adds so much to the air of elegance, which is the distinguishing feature of this part of the work. Messrs. Mangrum & Otter had here a splendid opportunity of showing their fine capabilities in this class of workmanship, and thoroughly improved it. The building throughout exhibits fine examples of their consummate and conscientious skill.

Upon every floor, and prominent throughout the structure, marbles of varied hues have been freely employed. In the stairways, along the walls and in exposed places, the artistic effects have been heightened and elaborated by a full use of marble. The richness of the general appearance of the interior has been greatly enhanced thereby. Messrs. J. Musto & Son have reflected infinite credit upon themselves by their admirable work besides proving so effectually the great resources of their establishment.

To Mr. G. Orsi was intrusted the painting, decoration and polishing of the new Poodle Dog building, which had to be completed in a style in harmony with the balance of the work, and required the highest professional skill in accomplishment. The careful workmanship and evident taste displayed by Mr. Orsi is greatly commended.

The artistic decoration of the establishment was placed in the capable hands of Moretti & Trezinni, the Italian fresco artists, who have demonstrated their high artistic instincts in the adornment of such edifices as St. Ignatius Church and others of equal importance in this city and elsewhere. In the Poodle Dog Building a fine opportunity was given these noted artists, and in the banquet halls of the upper story and the great restaurant on the lower floor, their felicity of design and fine execution showed to supreme advantage. The two allegorical groups in the restaurant are admirable in composition and color. They are the work of Henry Rascher, who was especially employed on account of his great artistic gifts. The composition on the ceiling in the vestibule of the ground stairway, at the street entrance, is the work of Mr. Moretti. It shows to especial advantage at night in the full glare of strong artificial light. It is a gem. The capacity of these gentlemen is displayed in the beautiful variety of the frescoes. Many patrons of the new restaurant will come often to look at the beautiful exhibits shown in the skilfully colored and groupings of the frescoes.

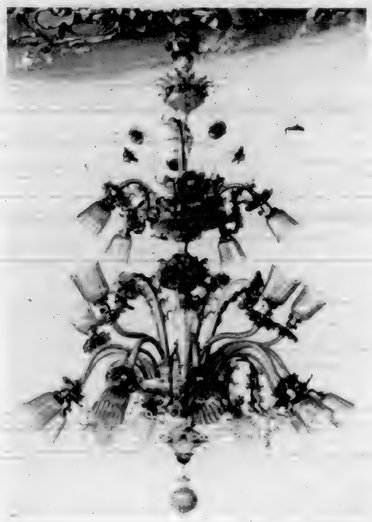
A building of such superior construction even though made absolutely fire proof cannot altogether dispense with the services of the carpenter. In this particular instance the presence of the master workmen are conspicuously manifest.

The wood work in this building is evidence of high artistic skill as well as splendid workmanship. When it is remembered that golden oak, curley birch, mahogony, maple woods were employed in the finishing of the costly suites in turn as well as in the great dining room of the first floor and the banquetting hall on the sixth, the services of highly competent workers in wood was extremely necessary, how Messrs. Campbell & Pettus have fulfilled their part of an arduous undertaking let their work speak for itself. The execution of the beautiful suites, each in a different kind of wood and rich in carving, testifies abundantly to their taste and skill.

Design of Handles on Entrance Door.

The perfection of detail displayed throughout the building is apparent to the most careless observer. In one respect, and in many others as well, the careful attention shown in the attention paid to minor matters has a very considerable influence upon the general effect as intended. No one who enters the building can fail to give his attention to the perfection and beauty displayed in the locks and door handles which were made expressly for the Poodle Dog by the Yale & Towne Manufacturing Company in special Fairfax designs, through Messrs. Dunham Carrigan & Hayden Company of this city. The locks in the main vestibule and the large restaurant are sure to be greatly admired and commented upon. They are of the Fairfax design in oxidized silver.

A particular feature of the main dining room on the first floor is the great chandelier in the center of the ceiling and the two smaller ones that flank it on either side, altogether the most beautiful examples of Venetian glass work on the coast. They are of light ruby in tint and blown in shapes of calla lillies and cactus flowers with the foliage of each, all



CENTER CHANDELIER IN MAIN DINING ROOM.

connected in serpentine branches. They are the importation of C. F. Kinsman of this city, imported under special designs from Vienna.

A word should be spoken for the tasteful, complete and lavish furniture, not only of the suites but of the reception hall, private dining rooms and also those designed more particularly for the general public. It was a difficult task to furnish so extensive an establishment in such perfect harmony and style but the California Furniture Company triumphantly fulfilled all requirements.

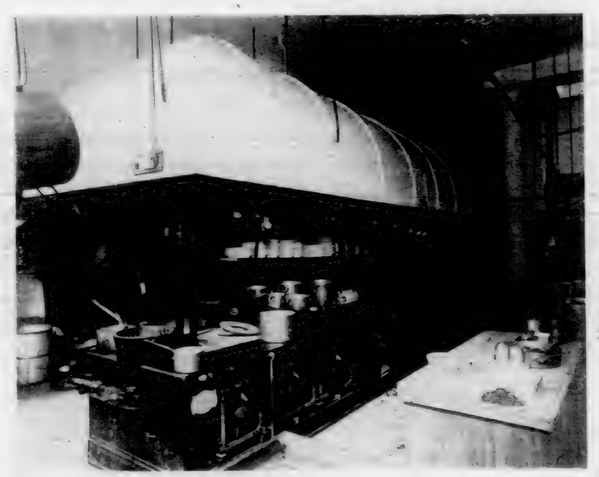
The department upon which the success of a great restaurant depends is often inconspicuous to the public gaze and sacred from intrusion to any one except cooks and waiters. The fitting up of the culinary department was done by the firm of John G. Ills & Co., and shows beyond doubt the capacity of that firm for such work. The great range on the first floor has capacity for 400 persons while the one adjacent to the great banquet hall is but little inferior in size. One special feature of the larger range is the arrangement for carrying the fumes and smoke from below instead of from above. A very great success.

The very handsome and roomy elevator is from the manufactory of Cahill & Hall and is a model of handsome design: every appliance for safety has been attached.

The care for the safety of those guests who are likely to fill the establishment at all times is evidenced by numerous reels for fire hose to be used in cases of extreme emergency. These hose reels are a special feature, furnished by R. S. Chapman and though the structure is fireproof they could not be dispensed with here.

The determination that every detail of this building should be absolutely perfect is evidenced by the introduction into every grate and chimney of the Clawson patent hoods and cross-bars, without which no chimney is complete, which were supplied by L. E. Clawson & Co. These devices are potent in assuring a perfect chimney and unobstructed draft; moreover, whenever employed, no workman, however careless he may be, can possibly construct an imperfect flue. All the best buildings in the city have introduced these valuable patents with most satisfactory results.

The final word in this eulogistic description of the last great building erected in San Francisco is in commendation of the fabrics of the Paraffine Paint Company who furnished the roofing and other required material that is to assure this great building protection from moisture. The architect speaks of this company in enthusiastic terms.



KITCHEN RANGE.

HYDRAULIC MORTAR.

CEMENT and mortar tests have been so extensively made and discussed that the subject may seem almost exhausted, but the value of such tests depends so much upon the manner in which they are conducted and investigated that a study as scientific as that made by M. Feret, the head of the laboratory of the *Ponts et Chaussees* at Boulogne, and published in the *Bulletin de la Societe d'Encouragement* demands recognition.

M. Feret first describes and tabulates the extensive series of tests for resistance to tension, compression, piercing, and shearing which were made in the laboratory under his charge, the same Portland cement being used in all cases, in connection with various kinds of natural and artificial sands, the intention being to investigate rather the physical properties of various mixtures than the comparative merits of different cements. The results are given in tabular form, and also plotted in curves, showing graphically the general

behavior of the materials, after which the effect of variations in a series of test samples is discussed.

Attention is called to the fact that widely different results may be obtained from the same material, according to the manner in which the tests are made, and emphasis is strongly laid upon the point that tests are not comparable unless they have been made in the same manner.

In tests for flexure, for instance, the size of the specimen is of great importance, since the distance of the outer and more resistant portion from the neutral axis has a great influence upon the result, and in general the greatest resistance of any specimen is found in that portion nearest the exterior. An unequal distribution of stresses must, therefore, appear in tension tests as well as in those for flexure, and this inequality is still greater when the mixture is not perfectly homogeneous.

According to the theory of resistance of materials, tests by flexure and by tension should lead to the same ultimate strength, but deductions based upon materials of supposedly perfect elasticity do not hold good for mortars, especially as the point of rupture is approached. M. Durand-Claye has shown that the resistance deduced from flexure tests is almost double that obtained from direct tension, and the tests of M. Feret bear out the fact that there is a definite ratio between the two resistances—namely, the resistance by flexure is to that by tension as 1.89 to 1, or, in round numbers, as 2 to 1.

Similar relations were deduced between the resistance to compression and to shearing and punching, a constant and proportional ratio being found. There does not appear, however, to be any such proportionality existing between the results obtained by tension and by compression tests, and two different mortars having the same resistance under compression may show very different results in tension. As a result of much experience deduced from many tests, M. Feret states that he believes the test by compression gives the real measure of the coherence of a mortar more nearly than does a tension test. In all cases the compression tests gave more uniform and consistent results, both for large and small specimens and for various conditions of homogeneity.

The most important part of M. Feret's paper, however, is that relating to the physical constitution of a hydraulic mortar, especially with regard to the size of ultimate particles of the materials employed, and to the thoroughness of the admixture.

For a very fine sand the resistance to crushing is much greater than for a coarse sand, the proportion of sand to cement being the same in both cases. A tabulated series of tests, using a constant quantity of cement and sand, but with different proportions of fine and coarse sand, showed that the resistance to compression was two and one-half times greater with fine sand than with coarse, and corresponding variations appeared with the other mixtures.

An approximate measure of the nature of a mortar in this respect may be obtained by determining the density, or, as M. Feret calls it, the "compactness," of the mixture, since this bears a relation to the proportion of voids between the particles, which doubtless plays an important part in the strength of the mortar. In plotting the results of the tests made with sands of various degrees of fineness, M. Feret uses the ingenious form of triangular pyramid adopted by Professor Thurston in his investigation of the strength of various bronzes, and in this manner the results are shown with a clearness not otherwise possible. Similar diagrams are given for mixtures of sand, cement, and pulverized slag, and the paper closes with data as to the effect of the addition of a proportion of puzzolana to cement and sand, especially for hydraulic mortars which are to be exposed to the action of sea-water. *The Engineering News.*

PRECOCIOUS ARCHITECTS.

WHE time may have been once when success in architectural design was a matter of accident, or when those to whom the creation of great buildings was entrusted could depend upon their instincts and the inspiration of the Muses; but we have changed all that with our modern civilization, and if their is any one profession of to-day that requires long and arduous preparation, it is that of the architect. Constant, unremitting study is the only safe program for the man who would take rank. It has been our editorial privilege to be called upon repeatedly for advice to those who contemptate becoming architects. The usual rule is to find the young man eager to enter an office, anxious to begin actual work, looking forward to immediate worlds of conquest. Even when a kindly restraining influence has harnessed him into the routine of one of our best technical schools, his impulse after graduation is still to build, to hang out his shingle, to get to work, and the idea seems to be that if by some mental *tour de force* he can compress into three years the amount of study that is laid out for five or six, it is well worth the effort. The difference between this point of view and the principle which seems to actuate the French students of architecture goes, perhaps, a considerable way towards explaining the manifest superiority of the French school in its methods. With us the aim is to complete the studies as speedily as possible and start to work. With them it is not in how little time can education be acquired, but rather how many years can the student devote to preliminary training. It is often discouraging to the aspirant, who has, perhaps, come from the Institute flushed with his diplomatic honors, to be told to take a humble seat and keep on studying for five or six years more before he allows his kind friends to give him a job, but all experience shows that our young men are apt to start too soon rather than to delay too long, and that, other things being equal, the man who hangs out his sign and begins his professional career with the greatest amount of experience behind him will have the richest measure of true success. The secret of success in any profession, in these days, is not inspiration, not native talent, nor even that *sine qua non* of the architect, good and complacent friends, but thorough preparation and unlimited, hard dig.—*The Brickbuilder.*

TRADE NOTE

BECAUSE of the excessive storm in this locality the roof of our brass and copper rolling mill caved in on Sunday morning, November 27, on account of which we have been somewhat delayed in filling orders for this class of material during the past week.

We have finished removing the debris of the wreck and have erected temporary constructions over the machinery, and the brass mill will be in full running order December 5, when we will have all the rolls running in this department, and will be able to furnish sheet brass to all of our customers promptly.

The entire brass and copper mill will be in full operation December 12. No damage or interruption occurred in any other department of the works, and the seamless tube, brazed tube, kettle and boiler plants were in full operation Monday morning November 28 as usual. The damage to the machinery was very small, less than $1000 and the cost of replacing the roof with a permanent and substantial wooden roof will not exceed $6000, or if an iron roof is used will not exceed $12,000, which expenditure will put the mill in better condition than before the accident. Very respectfully,

RANDOLPH & CLOWES.

SOME POINTS ON ESTIMATING.

IT IS the close figures that makes the most reliable estimate, and where contracts generally prove satisfactory all round. Every inch of material and every minute of time should be counted, and the figures should always avoid that dangerous risk "that's near enough." There is no such thing in successful estimating as "near enough:" "exactly right" is what is required, then you know what you are doing. Remember always, that it costs more to do the same work in an upper story than it does in a lower one. Doors, same size, equal finish, same time, and furnished with same style of hardware, cost from one to three per cent more to finish when in an upper story. The higher up, the higher the cost, and what is true of doors is also true of every other kind of work. It is utterly impossible to tell the exact cost of one part of a building by comparing it with the cost of a similar piece of work. You may get near it, but you should not be satisfied with that. It pays the estimator to estimate on everything and to be exact in every estimate. Avoid accepting figures that are not your own, and, above all, put no trust in estimates of cost as given in architectural books and journals, unless such estimates are itemized and you have gone over the figures yourself. Many a young builder has lost his reputation—and his money—by taking it for granted that a certain house, illustrated, can be finished complete for the sum stated in book or journal. These are traps and snares for the unwary—avoid them. Estimates obtained from an architect's office are generally correct so far as quantities are concerned, but are generally woefully lacking in the time, labor and prices. There are so many things the architect wots not of, such as scaffolding, handling material, and other things, that render his figures doubtful, that it is always better to make your own. It is just as bad to overdo an estimate as to underdo it, for in one case you lose your work and in the other your money, and in these days of close—yea, savage—competition, it is the man who figures everything, and figures exact, that takes the work. If you cannot estimate with confidence in your own ability, or have no trusted workman who can estimate, you had better let "contracting" alone, or you will find yourself in deep water before you are aware of it.—*The Canadian Architect.*

LESSONS FROM FIRE AND PANIC.

BUT THESE are matters in which we must expect no help or sympathy from the persons whose lives are thus safeguarded. Twenty years ago the densely crowded church of which I was the people's warden had outer doors opening inwards, and with the support of the vicar I insisted on an internal lobby with doors opening outwards. We did this in spite of unanimous opposition and as no panic has occurred the opponents may say they were in the right.

A few years ago a thoughtful architect provided to the west end of a church the only efficient arrangement of exit doors that I have seen, but fitted them with a lock. I went to the opening service to see the result. The place was full, even to standing room, and when the procession from the choir turned to come down the centre passage they could not advance a step. Then, if ever, was the time to throw open the exit doors, but the key was in the vicar's pocket, and he could not be reached except by means that would have been impracticable, and with delay that would have been fatal in case of a panic.

I think it probable that we may not again hear of the fitting up of one of our great churches for some important function with a forest of timber, in stages and seats and galleries, so that either through accident or through malice, a fire may be raised which might result in a calamity even greater than any that has hitherto been known. At the induction of the Dean of Canterbury, when a great crowd was expected, those in charge of the Cathedral were properly careful, and limited the admissions to those who could be accommodated with a reasonable chance of safety to themselves.

Our theatre regulations are made under the Metropolis Management Amendment Act, 1878, and have been much strengthened in recent years, largely through the advice of Sir E. M. Shaw, K. C. B., formerly the chief owner of the Metropolitan Fire Brigade, while the application of the regulations has become more stringent as their necessity has been more generally appreciated. They are applicable to all places where the public are invited, for music or dancing or stage plays, whether on payment, or by ticket or free. I can only mention a few of the things which must now be done in the case of a newly-licensed building, and which are demanded so far as is reasonable and practicable in the case of an old building. As to the latter there is an appeal to the arbitrator.

I am not sure that many theatre architects entirely approve every one of our regulations, but some approve certain of them and others probably approve the rest, for whereas a few years ago not many plans were submitted that would bear examination, there is now a large and increasing number of architects who, so far as their clients will permit them, produce excellent plans and heartily concur in our regulations as a whole. And as to clients, all the more experienced managers are alive to the risks of their undertakings, and very large sums have been willingly spent by them in the improvement of old buildings. Manchester has taken a good lead in theatre architecture. At the present time, when new theatres are being built in all our London suburbs, and even in small provincial towns, no class of buildings is better understood.

In London the site for a new theatre or music-hall must abut for one-half of the boundary upon public thoroughfares, one of which must be not less than forty feet wide. This is exactly one half of the requirement as to site in most continental cities, where, as in Manchester, the theatre must be entirely isolated. But our own moderate demand may be relaxed if the building is of small importance or if the design or surroundings seem to warrant it. We are now actually getting isolated theatres, whereas a few years ago there was not one in London. Not many years ago the owner of a site intended for a theatre would insist on devoting the best portion of his frontage to shops. If the site consisted chiefly of back land, the owner would consider it particularly eligible for a theatre. Of such a site I once said to the proposer, "Surely nature intended this for a coal yard," but he was careful to correct me—it had really been a timber yard.

Our regulations provide for the separation of dressing-rooms, and such sources of danger as workshops, stores, painting-rooms, property-rooms, scene-docks, engine-rooms, and gas meter rooms, and regulate the supply of gas, electric light, lime, light and water. They require a fire-resisting curtain and a high roof with lantern light over the stage. The mischief of window opening near adjacent property is sometimes imperfectly guarded against by protecting them with hoppers. Recently a fire was caused in a music-hall by an old accumulation of rubbish carried by the wind into one such hopper and fired by burning soot from a neighboring chimney. Our great difficulties arise out of staircases, corridors, and exits.

People who talk of clearing a theatre in two or three minutes fail to realize the suddenness with which smoke and poisonous vapors spread, nor do they appreciate the effect of a panic, which may prevent an audience getting out at all. If a fire breaks out among the scenery the whole is at light at once; the vapours make for the upper parts of the auditorium; and the people die where they sit. In the great theatre fires it has been estimated that all the victims died from suffocation within five minutes. These are matters which can be reckoned with, hence the provision of "fireproof" curtains and high roofs over the stage. But no one can reckon with panic. It needs no fire or other danger. It is a madness to escape from no one knows what. The exits from a public place must allow for panic as well as for fire. Two exits, well-lighted by some independent means, must be provided from every part of the building; and as one may be blocked, each must be capable of taking the whole of that part of the audience. They should deliver into different streets. One of these, which will also be an entrance, may be connected with a vestibule that is common to three entrances, and the doorways of this vestibule must be one-third wider than the combined widths of these three separate entrances. The least width for an exit is four feet six inches in the clear. Too frequently I find that the exits are actually made of this dimension between the brick-work, so that after deducting the thickness of doors and projecting handles only three feet four inches is left. I consider it unfair to expect one to overlook such mistakes in so important a matter.

All exit doors having fastenings must be fitted with bolts yielding to pressure from within. This necessary regulation gives rise to great difficulty. A manager will suspect that persons get access through these exit doors, and also that his servants get out an improper times. In view of the importance of this point, and the impossibility of securing by any system of inspection the opening every night of a door that has locks and bolts, it may be hoped that there is mechanical ingenuity enough to get over any such objection as I have indicated.

The impossibility of getting the employes about a public place to understand that exit doors and passages are meant to be at all times free and well lighted may be illustrated from experience. The first new theatre that was opened in my time had been rebuilt after a fire, and the proprietor, confident in his arrangements, invited my inspection on the opening night. I found the exits without lights and their doors blocked by the debris thrown out of the building at the last moment. In another case a few years ago the architect had provided admirable exits, but insisted on fitting the doors with locks. In the middle of the first performance I found every door locked and the key at the box office, to be used I was told if required. In a third case, when everything had been found in order, a final visit an hour before the opening disclosed that handsome fixed grills were being put to every exit door, only to be removed in case of need. We have found exit passages turned into lumber rooms, or obstructed by spare tables, by chairs intended for extra and illegal seates in the gangways, by perambulators, and by bicycles. In one case the exit was the home of a savage dog. The architect must never depend on the care with which his building will be managed, and in spite of good intentions the accumulation of spare scenery belonging to pieces that have been taken off or are coming on, and the storing of rubbish, is always a danger. In important continental theatres a separate warehouse is provided as near as possible to, but detached from, the building, and there all scenery and properties not actually in use are kept.

And with respect to this last consideration, experience teaches that in cases of sudden danger no audience, no crowd in a house or factory, and indeed no individual, can be trusted to take the obviously reasonable course to prevent accident or to get to a place of safety. Their escape must be ensured for them by the provision of unobstructed exits that are used habitually, that are as short as possible, and that will take a crowd of people as fast as they can get away. Thus the planning of a building in relation to its exits is often of even more importance than its materials or the question of its site and surroundings, which last is a question often beyond the architect's control. I have advised a theatre architect to begin by laying down on his plan eight staircases and ten or twelve exit doors, and then see whether he had room left for a stage and auditorium. This is more reasonable than planning first these last-named parts and then using up any spare corners for scanty and inconvenient stairs and passages.

There is no class of public building so risky as the parochial or mission hall or club room which exists for purposes of instruction or social recreation. The licensees of such places are very often too inexperienced to feel any sense of responsibility, and the amateurs who usually manage such matters have no sense of danger. Having consented to preside at an amateur charity performance when the stage had been fitted up by the company, I found the footlights to consist of a row of dwarf candles, each being simply struck down on a penny piece. During the play one of the canvas wings fell upon these footlights.

Unwarned by the Paris disaster, bazaars are got up regardless of the danger from stalls heaped up with flimsy materials and lighted up by Japanese lanterns, without any special means of fire extinction and with indifferent means of escape. In a particularly bad case, while the chairman of the committee was arguing against the possibility of accident, a lantern took fire and fell. No more than this is necessary to produce the worst of those accidents which such premises may be said to invite, and the contents of only one stall would have sufficed.

In view of the wide range of this Paper and the familiarity of this audience with the details of construction, I have for the most part been content to suggest principles upon which we ought to act. And on account of the importance of these questions in relation to the safety of life, I trust we shall agree that there is a moral duty in every one charged with the erection or care of a building to make it as secure against fire and panic as he can. I confess to some feeling approaching pain when an architect, assuming something like the position of a legal advocate, endeavors to argue that provisions made by law for the safety of life and property mean less than they are commonly supposed to mean, or struggles to get some relaxation of the law which, perhaps unfortunately, the public authority has power to grant. Every relaxation beyond what a prudent man would consider safe is in the nature of a wager that nothing shall happen during the whole time that the building will be in existence which will call for the particular precaution which on the responsible advice of the architect has been injudiciously omitted. It may be that the wager will be won, but the risk is considerable and always there; and this is a consideration which I desire to impress most strongly upon those who are charged with such responsibilities as I have mentioned.

THE END.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL, and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

See a full size working model at our store.

BUILDING NEWS.

CONCORD

Two-story frame; Owner, A. W. Maltby; Robert Farr; c. Reif & Ahlgren; signed, Oct. 5; cost $1650.

EAST OAKLAND

East 14th. To build; o, E. B. Stone; a, Albert Sutton & L. Whitnew; signed, Dec. 7; filed, Dec. 14; cost $2,0[illegible].

Eleventh Avenue east 21st. To build; o, Agnes and James Brown; c, Anderson & Stockholm; signed, Sept. 28; filed, Oct. 3; cost $1250.

FRUITVALE

Fruitvale station. To build; o, Laura A. Cowan; a, G. A. Reinemann; c, Henry Hahn; signed, Nov. 7; filed, Dec. 12; cost $1150.

OAKLAND

Eighth near Peralta. To build; o, George H. Garrett; a, W. H. Rutson; cost $2500.

Oakland View homestead association. To build; o, E. J. Steward; a, A. W. Smith; c, C. S. Ballard; signed, Dec. 2; filed, Dec. 12; cost $2061.

Linden street No. 1225. Alterations and additions; o, Lizzie C. and J. W. Nelson; a, A. W. Smith; c, Anderson & Stockholm; signed, Sept. 29; filed, Oct. 3; cost $400.

Moss Ave. near Broadway. Maternity cottage; o, Fabiola Hospital Assn; a, D. E. Oliver; c, Mohr & Pfluger; signed, Nov. 26; filed, Nov. 29; cost $1200.

Sixteenth and Myrtle. To build; o, Carrie L. Booth; a, E. H. Barnes; signed, Dec. 1; filed, Dec. 5; cost $2300.

Webster near Durant. To build; o, S. R. Sempham; a, William Kirk; c, Flint & Libbey; signed, Dec. 13; filed, Dec. 16; cost $1747.

SAN RAFAEL

Lot 3, block 8 Townsite. Heating, ventilating, etc; o, Board of Education; a, Cunningham Bros; c, Morgan Bros; signed, Nov. 18; filed, Nov. 26; cost $200.

Margarita Tract. Club House; o, San Rafael Golf Club; a, Newsom & Meyer; c, Jensen & Schlosser; signed, Dec. 2; filed, Dec. 6; cost $2200.

Lot 3, block 5, Townsite. School building; o, Board of Education; a, Cunningham Bros; c, Thos. O'Connor signed, Nov. 19; cost $10,145.

LOS ANGELES

Architect Geo. H. Wyman has prepared plans and is now taking bids for the estate of M. Mueller, for a two story and basement business building which will connect with the present building on the north west corner of Fifth and Broadway. The outer dimensions are 6x100 feet. The front elevation will be laid up in Sespe stone. The first floor is designed for the use of the Los Angeles Electric Company and the second floor for apartments. The inside finish will be in Oregon pine. A cement floor will be laid in the basement.

The same architect has prepared plans for the Soldiers Home, for an additional story to the hospital building 40x100 feet, to be used as nurses' quarters also for a two-story frame building 64-68 feet to be used as a bakery; the bids for which will be opened to day.

$5,000 Worth of Plans, Drawings and Details for Only $4.00.

Pallisers New Cottage Homes

With Detail Drawings.

The best, the largest and the most practical and complete work ever issued on plans of medium and low cost houses, containing one hundred and sixty new and original designs for cottages and villas, including every description of modern dwellings for the seaside, the south, winter and summer resorts, etc., double houses, country houses, city, suburban, town and city residences and apartment houses, of every kind and variety, in every conceivable combination of stone, brick, timber, plaster and frame costing from $5 to $7,000, giving all the comforts and conveniences, and suited to every taste, location, want, etc., also 50 new designs for city, brick block houses. The whole affecting the largest field of selection from the most approved and latest style of architecture. Illustrated by plans, elevations and perspective views from practical working drawings to a uniform scale, and not like the impractical sketch views which fill so many cheap architectural books that are in reality issued only as catalogues and price lists of printed plans. 1500 detail drawings covering the whole range of interior finishing and interior construction and perspective elevation of the plans in this work and all to a uniform large scale. Cabinet work of every description, mantels sideboards, bookcases, cabinets, dresses, etc., in almost endless numbers and variety. Stairs, hand railings, newels and balusters. Details will be found to cover every question that can arise in constructing dwellings of every kind. Fences, summer houses, pavilions, conservatories, arbors, well curbs, outbuildings, etc. Twelve new designs for stables and carriage houses, descriptive letter press, giving practical suggestions, cost, etc., which would alone fill an ordinary book of 150 pages. Details of furniture of every description, so plain that any good mechanic can understand and execute the same. Perspective views of four houses printed in colors, showing how to paint. Specifications and form of building contract, etc. The value of this work to builder cannot be estimated, as it contains plans and details for just such houses as they are called on to build every day. There is not a contractor or builder in the country that can afford to neglect this book. Building mechanics should all possess it. No matter what kind of a job they are called on to do, here are the ideas to help them out. Ideas are as necessary as tools and this work contains thousands of practical ideas. It is the educated mechanic that goes to the front every time. Prepared by PALLISER, PALLISER & CO., the well known architects in one large volume 11x14 inches, printed on heavy cream paper, handsomely bound in boards and leather and sent to any address, on receipt of $4.00 by the

LACONIC PUBLISHING CO.,

Palliser's Useful Details

AN IMMENSE WORK

New Edition just published in paper portfolio, 14x22 inches, good paper and good prints. An entirely original and practical work that should be in the possession of every carpenter, builder, woodworker, stair builder, sash, blind and door maker, cabinet maker, mason and plasterer and all building mechanics. *The American Architect and Building News* says of this book: "We have often wondered that some American publishers did not undertake to produce such a book, for it has been evident that a large sale could be found for a work showing American constructive details of a good character, but at length has appeared just the work, and which has about it the indications of a useful and successful undertaking.

Useful to those who buy it and successful as a business adventure for the authors and publishers. Grouped upon single folio sheets are a multitude of details well arranged and properly coordinated, of such constructive features as must be wrought into the small houses, stables, shops, etc., in which construction nine-tenths of the mechanics an a large proportion of the architects of this country find occupation. Useful details as they are properly called. 'When one sees the prodigality with which the authors have made public their ideas, one cannot but smile afresh at the remark of a foreign architect "When I got an idea I wouldn't be giving it to the other fellows, I'd be keeping it for my own work.'" *Carpentry and Building* remarks about "Useful Details": "The plates are large and withall are crowded, as though space were valuable. This is in one sense an advantage, since many more designs are obtained for the money expended.

We will send this great work, prepared by PALLISER, PALLISER & CO., the best known architects in the world, to any address, prepaid on receipt of only $2.00. Address all orders to

Every Man a Complete Builder.

A $5.00 BOOK FOR ONLY $1.00

How to Build a House

Be your own architect

This book will save you hundreds of dollars. If you are thinking of building a house you ought to buy the new book, PALLISER'S AMERICAN ARCHITECTURE; or, Every Man a Complete Builder, prepared by Palliser, Palliser & Co., the well-known architects.

There is not a builder, or anyone intending to build or otherwise interested, that can afford to be without it. It is a practical work, and the best, cheapest and most popular book ever issued on building. Nearly four hundred drawings. A $10 book in size and style, but we have determined to make it meet the popular demand to suit the times.

It contains 101 pages 11x14 inches in size, and consists of large 9x12 plate pages, giving plans, elevations, perspective views, descriptions, owners' names, actual cost of construction, NO GUESS WORK, and instructions HOW TO BUILD, 70 cottages, villas, double houses brick block houses, suitable for city suburbs, town and country, and costing from $800 to $6500; also barns, stables, school houses, town halls, churches and other public buildings, selection of site, employment of architects. It is worth $5 to anyone, but we will send it in paper cover by mail, postpaid, on receipt of $1.00; bound in cloth, $2.00. Address all orders to

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

WHILE the people of the middle and western states provide themselves with caves to avert the fury of cyclones, which from their instantaneous attacks coupled with great power, are a standing menace to property and life, the people throughout the United States submit tamely to be without protection from a danger more terrible than the cyclone, namely, fire. So accustomed are we to putting our trust in our own care, in fire companies, and in insurance companies, that in the midst of the most inventive age the world ever saw, the conditions as to fire remain the same. No, not the same, for in times past people built more solidly, and of materials that would, for a short time at least, resist the progress of fire, as would heavy timbers, and stone walls. To-day, houses erected for the sheltering of valuable property and precious lives are the merest shells—worse than shells, for they are tinder boxes, light and inflamable, story over story, built in blocks and in flats they seem to invite conflagration. The use to a very great and growing extent, of inflamable oils for fuel and lighting increases the danger. A mis-step, the accidental overturning of a lamp, or, as frequently happens, an explosion, starts a conflagration which may consume the product of the labor of years for many householders, may destroy the gains of corporate industry to a vast amount, or lay in ashes the property of the municipality.

But that is not the worst of it. Every now and then there is a holocaust, when some great hotel, some theatre, or other place of entertainment, takes fire, and many lives are sacrificed. Everything depends upon the firemen, who amid fearful perils are striving to save frenzied people, suddenly confronted with a horrible death. Too often in their efforts they go down, themselves, the victims of the existing conditions.

Why is it that this ever present haunting threat of death by fire is not met with that intelligence which is applied to other affairs. If those who live in dread of cyclones provide means of safety from the storm which may come any day, shall not we who live in hotels, flats, or in blocks of tenant

houses be made comparatively at least, secure from a never absent peril? The ancients suffered much less by fire than we. The causes of their exemption are not far to find. Their public buildings were of stone, and their decorations were not of a kind easily ignited or affected by heat, being mostly of sculpture, and of painting on hard walls. In warm countries there were no arrangements for heating, and the only fire introduced was the sacred flame kept alive by constant attendance, on the altars of their Gods. Their dwellings also were of adobe, brick, or stone, not high, and had non-combustible roofs. Even in streets where a wheeled vehicle could not pass conflagrations were rare, and seldom extensive. In the colder countries of Northern Europe their was similar immunity, the great fire-place with its logfire, or in more modern times the porcelain store, being unproductive of accidents. Not so with us. We build to burn, and with our resinous lumber, our paint and varnish, our lavish furnishings and our elevator shafts to produce the fatal draft, we resign ourselves to our fate.

When is the man going to appear who will find a remedy for this condition? How are we to render safe our public or our private buildings, in whole or in part? Who will produce, and teach us how to apply the material which will make wooden houses fire-proof? Failing in that, who will so construct a building that some portion of it, say the hall and staircases, will be a safe refuge for a reasonable time, where helpless people may await succor or find means of escape? Some flooring ought to be invented which could not be eaten up by flames before persons suddenly awakened out of sleep could reach and traverse it. In the same way certain walls should be made secure against the irruption of flames. Probably builders will at once fancy that to effect such changes will involve great expense. But granting that it would, which is by no means certain, the money saved in the long run in the general outlay of cities would be quite sufficient to cover the additional cost, while public buildings would undoubtedly improve in the direction of permenancy and good taste.

THEN AND NOW IN ARCHITECTURE.

TAKING Egypt, as we have, for the starting point of architectural orders, and assuming as we must, that Greece derived her fundamental ideas from Egypt there are still some questions remaining unanswered as to the means by which this knowledge was conveyed to Greece, and the route taken. From about the time, 1300 B. C., that Moses led the Israelites out of Egypt, temple building ceased, and architecture declined. But in the meantime Assyria had risen into power, and exhibited its affluence and its pride in costly structures, which however, took the form of palaces rather than of temples. The materials of which they were built were not able, like the granite of Egypt, to resist the tooth of time, and they crumbled to the ground carrying their history with them. Enough only remained to show that the general form of their palaces was square; that they were built upon a raised platform, and approached by stairs, or by long slopes. A large courtyard was a feature of these buildings, placed at one side of the platform, instead of centrally, the apartments opening upon it. The walls of the oldest building yet discovered in Assyria dating back more than 2200 B. C., are built with a series of vertical projections thickening them at regular intervals like a pilaster or a straight buttress, and later walls have the same vertical treatment in the form of reeds, which would suggest Egyptian derivation, especially as they are alternated with flat surfaces which may have been reserved for decoration. In certain details also, the Assyrian architecture followed Egyptian examples. But the most striking similarity between Egyptian and Assyrian ideas was the placing as guardian at their gates the Sphinx—a bull with a human head, and winged—in which respect it differed from the Egyptian sphinx. That the Assyrians modified, and as they believed, improved upon the earlier styles of Egypt, a declining power, is a natural conclusion.

Several centuries later, after having reached a height of luxury which made her the envy of the neighboring nations, Assyria hereself was conquered by the Medes and Persians, who in their turn became copyists of whatever they chose in the works of the subjugated people. The resemblance between the palaces of Assyria and Persia are remarkable, even to the placing of them upon platforms, approached by a grand flight of steps. Although like those of Assyria they were constructed of perishable materials, enough is left to show a more artistic spirit than that they displayed in their models. Even the slab supporting each step of the grand entrances of the palaces at Persepolis was decorated with bas-reliefs of royal sports in the hunting field, and groups of royal personages with their attendants. The remains of the Egyptian type of building are seen in the placing of columns, equally spaced, inside their great halls, although it could not have had the motive or the meaning attaching to them which it had in Egypt where they were used in the first place to support the roof, and in a religious sense to deepen the solemnity of the approach to the mystery concealed in the darkest chamber of their temples. In the Assyrian palaces small windows may have been placed near the top of the wall, above the line of capitals of the lower ranges of columns, as was sometimes done in Egypt, in what are termed hypostile halls, which were thickly set with columns, of which the side rows were lower, leaving a space above the lintels which could be utilized for the admission of as much light as was sifted through barred stone windows. The Persians, while evidently expending vast sums upon their architectural creations, evolved little that was worthy of imitation. They obtained certain details plainly Egyptian, and like every nation which has left us architectural remains, attempted to form new orders of capitals for the pillars or columns first designed in the Nile country. One of these seems wholly a reminiscence of Egypt, with its reedy column, and its spreading top like the seed-pod of the water-lily—very simple and pleasing in so far as it retains this character, but awkwardly surmounted by a bundle of reeds with curling ends, forming another capital inferior in character to the first, and spoiling the effect of the whole. On the other hand the bull capital, which is a double bracket facing in opposite directions, has a decidely artistic effect, and is peculiar ot Persia The roofs of Persia, like those of Egypt and Assyria were usually, and necessarily, in their columnar halls particularly, flat. There have been found, however, on their bas-reliefs some representations of domed buildings. Whether they were fanciful or were reminiscences from Asiatic sources imported by foreign artists is not certainly known.

The developement of architecture, as recognized by us, proceeded westward through Asia Minor towards the Mediterranean; but here as in Assyria and Persia, the materials used lacked this enduring qualities of Egyptian stone, and remains of any value are rare. Many interesting examples are found of the more ancient rock-hewn temples and monuments. The period of their execution is suggested by their imitation of timber construction, even to the hewing out of the beams on which the floor is supposed to rest, and the projecting ends of other beams and supports used in a wooden building. Some of these houses are cut out all round, and have gabled roofs, with a frieze, cornice and triglyphs under the architrave, thus mingling some of the architectural features of stone buildings with those belonging to a period when architecture as a science did not exist. Subterranean tombs and galleries have also been discovered with the stones laid in regular courses, the printed arch being used for the openings, and are supposed to date about 1000 B. C. Not strictly belonging to architecture, they may be referred to as guides to some subsequent developments of this science. These are not peculiar to Asia Minor, but are found also in Greece and Italy, and are known to writers on architecture as "Pelasgic".

That which strikes us in following the traces of an art or a science, is not that we are able to discover proofs of the migration of certain forms of civilization, but that such long periods of time as centuries should have passed between these movements, the territories often lying adjacent. Two reasons are historically given for this, namely, the jealousy with which each nation guarded its frontier from invasion and the prohibition of foreign forms of worship. As temples were the expression of religious ideas they could not be copied except by people who had first embraced the religion they represented; wholly, or in part. Owing to this inhibition we do not find the Egyptian temple proper in Assyria, although through wars and commerce many features of Egyptian architecture were grafted upon whatever original ideas these people possessed. In like manner some of these characteristics were carried beyond into neighboring nations, and modified according to the sentiments of those receiving them.

There is not in Grecian architecture the same evidence of an amalgamation of styles that is found in Assyria or Asia Minor, but there is apparent a deliberate choice of Egyptian styles, with also a deliberate intention to improve them. The Egyptians were not naturally an artistic people. They built up slowly and ponderously an impressive but not a beautiful style. The Greeks, on the contrary, having attempted the development of art had various examples to choose from. With their extraordinary love for, and insight into its true principles, they arrived in the course of two or three hundred years at a greater perfection than Egypt had attained in as many thousand. Without aiming at originality in the creation of orders, taking for models those originating in Egypt, they preserved the principal features, treating them in a manner reminiscent of the founders yet with a result quite different, more refined and more beautiful. The Greeks, like the Egyptians, were temple builders, both nations being polytheistic, and worshipping the same deities under different names, and with less austerity; and these differences had undoubtedly some influence in modifying their architectural creations.

The points of likeness and unlikeness which are to be observed are, for the former, the simplicity of shape and the use of columns to support beams over head instead of any arched or domed support: for the latter, the different disposition of the columns, and the change from a flat to a sloping roof, with the additional features of the architrave, frieze, cornice and pediment. Having formed a style they adhered to and perfected it, making it the admiration of the world for all time. Out of the heavy and rather squat Egyptian models they produced the light yet strong and symmetrical Doric column; stripping it of all suggestion of natural objects such as were characteristic of the parent style, retaining only the vertical lines of the fluting as essential to the upward effect. The Doric capital was entirely without ornament, being a simple block expanding by graduated curves towards the top into the just mathematical proportion to express its purpose in supporting the entablature. Indeed, the perfect charm of this style of columnar architecture was its scientific proportion, and its delicacy of finish, corresponding with it. This care as to effect is illustrated in the elevation of some straight lines into curves to correct optical illusions. There was a deviation made of about half an inch from the straight line in a height of a little more than thirty-one feet in the Doric column, to prevent the tendency to appear slightly hollow. Accurate observation has shown that this long curve has its apex about one-third up the shaft. In accordance with this principle in optics the steps of the Parthenon, the top one of which measures one hundred feet in length, gave an unward curve of about four inches, and the end cornice is carved to correspond. On the other hand, an angle column was made slightly thicker than the others to allow for the lessening effect of a dark object seen against the light. Not only these optical illusions were rectified in the best specimens of Grecian architecture, but the whole body of columns was made to lean slightly inwards, while the entablature was given a just discoverable backward deviation from the perpendicular. So nice was the Greek sense of symmetry, recognizing that principle in pictured art which requires an object to be represented as it seems, rather than as it actually is; and in architecture to make it seem as it should.

In both Egyptian and Greek architecture the column was the main feature. The Egyptian built walled temples with several chambers opening into each other, each smaller than the preceding one, giving them great longitudinal extent. The larger and outer one enclosed rows of columns, and was not roofed. The second chamber had also its rows of columns, and was only dimly lighted from the first (except in the so-called hypostyle halls); the third chamber was filled with a forest of columns obstructing the view completely; and the fourth or last, had a group of columns before the entrance on the inside. The several chambers were separated by walls, the doors being in the centre and opposite to each other. The last partition however, was pierced on each side of the main entrance to give access to several smaller chambers or cells. It was here that the sacred "mystery" of the Egyptian religion resided. The Greeks, on the other hand, placed their columns outside of the temple walls. The eastern *cella* of the Parthenon, one hundred feet in length, which contained the magnificent ivory and gold statue of Athene, and the Virgins chamber beyond it, were concealed from view by the outer and inner rows of columns surrounding it which formed the portico, and was thus given a semblance of the seclusion of the Egyptian temples. But the spirit of the whole was different. One represented an impenetrable idea, the other invited observation by its exquisite charm and ease of approach. The

Athenians had also chosen an elevated position for the temple of their tutelar deity, another method of removing it from profane encroachment. The Parthenan was built of white marble on a base approached by three steps which was one hundred feet front and two hundred and twenty-eight on its sides. From the uppen step to the top of the pediments was fifty-seven feet. The portico had on its outer edge forty-six columns, eight supporting the pediment at each end, and fifteen on each side exclusive of the end columns. Within the outer row, and two steps higher than this, was a second row of columns. The spaces of the inter-columinations, and the size of the capitals vary slightly, according to their position. Upon the eastern pediment the sculptures related to the birth of Athene, and consisted of independent statues resting upon the cornice. Upon the western pediment was represented the dispute of Minerva or Athene with Neptune respecting the land of Altita. The Metopes upon these of Egypt; and the statues, although showing just proportions, having all a conventionally smiling countenance without expression. On these, and on the sculptures of the best Athenian period, color and gilding were used, traces of which remain on the frieze of the hall in which stood the statue of Athene. This practice was directly derived from Egypt.

As to the domestic architecture of Greece, there could have been only differences between the Grecian and the Roman houses. Examples of the latter which have been uncovered at Pompeii, showing the same elegant simplicity of the Egyptian houses of the best period of refinement in the Nile valley. In the centre of the dwelling there was usually a garden, in the middle of which was a marble basin with a fountain flowing into it, the whole enclosed by a portico of columns. Figures of lions, children, dogs, fauns and other animal forms were grouped about the fountain. The rooms

the frieze represented in bas-relief the battles of Hercules and Theseus, the centaurs and Amazons, with other mythological and historical subjects. The frieze around the upper border of the cella represented the Panathenaic festival in honor of Minerva which occurred every four years, and was the highest festival of the Athenians. At this time the sacred garment, or peplos, woven and embroidered by Athenian maidens, was borne in procession to the temple. This ceremony, as represented on the frieze, has the peplos preceded by Gods and Goddesses, and followed by Virgins with offerings, and by horsemen, chariots, and sacrificial animals. Amid hundreds of figures no two of which are alike, all are full of action, grace and majesty. Such was the perfection to which the Doric order of architecture, and sculpture had attained in the Periclean age, about four-and-a-half centuries, B. C.

Two other orders the Ionic of Asiatic origin, and the Coriuthian mainly Egyptian, were developed. Yet the earliest examples of Grecian art found at Corinth, dating somewhere between 500 and 600 B. C., are distinctively Egyptian in proportion, the columns being even more massive than constituting the dwelling surrounding the garden, had their walls painted in red and black, which contrast produced a pleasing effect in a semi-obscurity. Arabesques of a charming alainess were used to relieve the dead level of the foundadation color—not copies of familiar objects, but gods and goddesses, cupids, dancing women, young girls in graceful attitudes, slight landscape views or a half mythical animal like the griffin—the coloring of the decorations being designedly subdued, the object being to entertain the mind without subjecting it to the fatigue of criticism, by suggestions of poetic grace with healthful activity. Such might well have been a Grecian house. Music, dancing, and recitation of verse were Athenian accomplishments. The dwellings of the lyric poets were conservatives where pupils thronged to be taught, and which furnished choruses for funeral or wedding pageantries. The Athenians believed that their gods were gratified by the spectacle of beautiful well-developed bodies in all attitudes displaying health and strength. This made their most sacred festivals operatic processions, and displays of grace. The influence of this an sculpture in teaching attitudes, was inestimable; it made their bas-reliefs

seem moving. The Olympic games and gymnasium tended to the same result.

From the Greek love of beauty, grace, poetry and activity, came the idea of the theatre, which was a place for the display of all these. It was a building, at least not an enclosed one, but an amphitheaterin the open air. The site selected was a concave slope, laid out with concentric stone seats in rows raising one above another. The usual form was semicircular, the centre being reserved for the orchestra, which fronted the rather narrow stage, backed, it is supposed, by a colonade. A colonaded gallery sometimes ran around the upper circle. The colosseum at Rome, derived from the Greek theatre, was more strictly architectural being built up from the ground, and its outer walls pierced with arched windows between which were pillars or the semblance of them, placed merely for ornament. The one exception discovered, to the semi-circular form of Geek auditorium, is found at Megalopolis, of date probably about 370 B. C. It is square, with parallel rows of columns, one within the other, carried completely around three sides; the columns being placed in radiating lines from the centre of the fourth side, or stage, to interfere as little as possible with the view of the spectators. This idea is the exact opposite of the Egyptian method, of obstructing the view by the arrangement of columns, as the motives were opposite—one to impress the spectator with awe the other to give him pleasure.

The Grecian tomb, as described by Homer, and the few examples descovered, have little resemblance to the tumuli of Egypt, except that they may have had a pyramidal roof. They had neither the extent, nor the significances of the pyramids of the Nile valley. One mausoleum, at Halicarnasses, appears to have been constructed in steps, and had a chariot group at the apex. But however slight the resemblance, in every order and style of Grecian architecture, and however modified by other influences, we find the germs if not the flower of the temple building worshippers of Osiris and Isis.

To be continued.

THE SENATE AND THE SUPERVISING ARCHITECT.

HE Senate, as in Commiittee of the Whole, resumed the consideration of the bill (H. R. 11414) making appropriations for the legislative, executive, and judicial expenses of the Government for the fiscal year ending June 30, 1900, and for other purposes.

The reading of the bill was continued to the end of the clauses making appropriations for "Office of the Supervising Architect," on page 35, line 12.

Mr. Cockrell—I should like to ask the Senator from Illinois to what extent the provision on page 34 and 35 has been carried out in the Treasury Department? The provision reads:—

And the service of skilled draughtsmen, civil engineers, computers, accountants, assistants to the photographer, copyists, and such other services as the Secretary of the Treasury may deem necessary and specially order, may be employed in the office of the Superviaing Architect exclusively to carry into effect the various appropriations for public buildings, to be paid for from and equitably charged against such appropriations: *Provided*, That the expenditures on this account for the fiscal year ending June 30, 1900, shall not exceed $210,000, and that the Secretary of the Treasury shall each year in the annual estimates report to Congress the number of persons so employed and the amount paid to each.

To what extent has that been carried out? In other words, when a public building is authorized to be erected, does the Supervising Architect of the Treasury under this provision employ draughtsmen to complete the drawings, the plans, the specifications and the estimates, so that the Supervising Architect can advertise and make a contract for the completion of the entire building within a given reasonable time?

Mr. Cullom—All that I know about the subject is found in the "Book of Estimates," on page 353:—

APPENDIX B.

In connection with the estimates for "Salaries, Office of Supervising Architect.

List of employes in Office of Supervising Architect, Treasury Department, and amounts paid each, during the fiscal year ended June 30, 1898, from appropriations for public buildings, furnished under requirements of the Act of Congress approved March 15, 1898, "Statutes at Large," vol. 30, p. 288.

Then follows a long list of names, the positions the persons occupy, the salaries they get, and I think, if it could be run down to the end, it would show exactly where the money goes in connection with each public building.

Mr. Cockrell—But what has been the effect of the requirement or authorization? Has it hastened the completion of public buildings?

Mr. Cullom—I confess I am not able to state whether it has or not.

Mr. Cockrell—We authorize the construction of a public building and limit the cost. The building goes on year after year, and there is no reason on earth why there should be such delay.

Mr. Cullom—I agree with the Senator fully; but that seems to have been the state of the case for a good many years.

Mr. Cockrell—It has been the case indefinitely—at least for a long time

Mr. Cullom—I suppose if we had time to investigate the report in the "Book of Estimates" it might explain very much of this matter, but that is all I know about it.

Mr. Cockrell—We have a public building on Pennsylvania Avenue, the City Post-Office Building; we have a building at Kansas City, which has been under construction I do not know how long; and there are other public buildings which will require years and years to complete. No individual and no corporation in this country which constructs a building of that kind ever lets it hang on their hands, year after year, with a superintendent and a parcel of employes drawing salaries out of the appropriation, thus reducing the amount that is actually put into the building.

Mr. Cullom—I fully agree with the Senator that that has been the history of all our public buildings under the system which has been pursued for an indefine time. I have myself alway felt that when a building was begun by the Government its construction ought to be vigorously prosecuted until it is completed and the people who had been employed discharged. I suppose such employes will be discharged if

they ever get a public building finished, but they never seem to succeed to that extent.

Mr. Cockrell—They seldom get a building finished. I see in another branch having coequal authority with this body a large number of bills have been passed for the erection of public buildings. These buildings cost from $50,000 to $100,000 or $200,000 or more. There is no reason in the world why a $50,000 building, a $100,000 building, a $150,000 building, or a $200,000 building should not be completed in one season. Any individual can do it, and if the Supervising Architect of the Treasury cannot secure persons who can draw the plans, specifications, and details of such work we ought to take the construction of public buildings out of his hands, and place it in the hands of somebody who will do it.

Mr. Cullom—I agree to that fully.

Mr. Gallinger—Mr. President, in that connection I wish to say that I have been very much interested of late to notice that when we propose to erect public buildings we now provide that private architects shall enter into competition in the matter of furnishing plans, as was provided in the case of the Library Building, and I think a similar provision was made for the public building in Chicago. In other words, Mr. President, we have this bureau in the Treasury Department and we have a very expensive force there, and not only are we dawdling along in reference to the erection of public buildings, but we are now commencing the policy of taking from them the work which, under the law, properly belongs to them.

I recall the circumstance that when a Supervising Architect was recently appointed it was done under the civil-service rules. A man came here, a very distinguished architect, who has erected some of the finest buildings in this country. He had not written a letter with his own hand in five years, he told me, but he is one of the most distinguished architects in the United States. He was put down to a table and compelled to write without cessation seven or eight hours, and of course he did not pass a very good examination.

Mr. Cockrell—Will the Senator permit me to ask him a question?

Mr. Gallinger—Certainly.

Mr. Cockrell—Do I understand that a civil-service examination was held for Supervising Architect of the Treasury?

Mr. Gallinger—Certainly; and the man who occupies that position to-day is a product of the civil-service system of the United States. After obtaining that position by a civil-service examination, which, to my mind, is an absurdity, we are now discrediting him and saying that he is not competent to make plans for a public library in Washington or a public building in Chicago, but that we must let out the job to an architect who could not pass the civil-service examination. That is all I care to say on the matter.

Mr. Cullom—I want to add to what the Senator has said that I tried very hard to bring about some sort of system by which an architect could be chosen without going through that performance, because no first-class architect would agree to it. The result is that we have got the kind of a man who has been described—I do not know who he is—and no community as to which a bill has passed for the erection of a first-class public building is willing to trust to the Supervising Architect to build it. So it is in Chicago. We have an architect for the public building there who is a first class architect, and he is in charge of that building because, so far as I was concerned, and so far as the people there were concerned, we were unwilling to leave it in the hands of an architect such as was usually selected by whoever might be the Secretary of the Treasury.

So I agree with all that has been said about this matter, and I sincerely hope that some of these days we may agree upon a plan that will result in securing an architect who is capable of taking charge of public buildings and constructing them within a reasonable time and in a proper way.

Mr. Gallinger—Or else abolish the office.

Mr. Cullom—Yet; or else abolish the office. I agree to that.

Mr. Cockrell—Mr. President, Judging from the declarations made in the Senate occasionally, and those made by my good friend from New Hampshire, Mr. Gallinger, and those made in another body not a thousand miles distant, the civil-service law must be a terrible failure, for all the sins of maladministration are charged to that law. I want to defend that law, although it may not need a defence. It is not the civil-service law, I say to my friend from New Hampshire, that is to blame for a Supervising Architect being subjected to such an examination under it, but it is the President of the United States.

Mr. Gallinger—Mr. President I do not know that I go that far in agreeing with my friend, but on general principles I agree with him that it is somebody outside of the law. I have never very seriously attacked the original civil-service law, in fact, I am in favor of it.

Mr. Cockrell—All right.

Mr. Gallinger—But what I have attacked has been this aggression, this reaching-out, this grasping of power and bringing under the law classes and individuals who, in my judgment, never were intended to be included in the law and never ought to have been included in it.

Mr. Cockrell—In that I heartily agree with the Senator from New Hampshire. He is exactly right. It is not the law, but it is the executive authority which takes these places and puts them within the provisions of the law. It is within the hands of the President at this moment to make any change he chooses.

Mr. Allison—Will the Senator inform the Senate when the Supervising Architect of the Treasury was placed under the civil-service law?

Mr. Cockrell—I have no idea when, and it is a matter of profound indifference to me whether it was done by the predecessor of the present incumbent of the Presidential office or done by the present incumbent. By whomsoever done, it was unnecessary and unjustifiable, in my opinion.

Mr. Gallinger—It was done for the first time, I will say to the Senator, when the present incumbent of the Supervising Architect's Office received his appointment. I know that from the fact that a friend of mind, a very distinguished architect, came here seeking that position, and, to his surprise, he found that he had to go through a civil-service examination.

Mr. Cockrell—When was the present Supervising Architect appointed?

Mr. Gallinger—I should say two or three years ago, I think, as I remember the matter.

Mr. Cullum—This situation I think, prevailed under a previous administration, but I am not sure when it began.

Mr. Gallinger—It never prevailed before the appointment of the present incumbent, I will say to the Senator, whenever that may have been.

Mr. Cockrell—But the present incumbent, my recollection

is, was appointed by the present President of the United States.

Mr. Allison—As I understand, he was appointed under an order spreading the blanket of the civil-service law over the Office of Supervising Architect.

Mr. Cockrell—Under President Cleveland's order?

Mr. Allison—I think so.

Mr. Cockrell—Then it was the duty of the present incumbent of the Presidential office, if he did not approve of that order, to refuse to carry it out, to rescind it. The orders of one President, under the civil-service law, have no binding force upon his successor, and his successor has ample authority to make any change or modification he may desire.

Mr. President, I desire to express my hearty approval of what the Senator from New Hampshire, Mr. Gallinger, has said in regard to the administration of the civil-service law. The order extending the operation of that law to its present scope is, in my opinion, the most deleterious action which could have been taken. The idea of putting a messenger, or a watchmen, or a laborer, or a copyist, or a cook, or any employe of that kind under the civil-service law is, to me supremely ridiculous. I see no justification for it. The selection of an officer of the character necessary to fill the position of Supervising Architect, with all his responsibility, should never be left to a mere technical examination. It is too important an office for that. There are millions and hundreds of millions of dollars entrusted to his expenditure, and in the large cities where public buildings have been authorized they are commenced and they are hardly ever completed. Before such buildings are completed they run almost through two or three administrations. That is not done in the private affairs of individuals and corporations and bodies that erect large buildings, and there is no reason why it should be done by the Treasury Department of the United States.

It is just as easy in these buildings to draw the plans and specifications entire for the whole work, let it out by contract, and have it completed within a given time, as it is to do it by piecemeal. Now a contract is let out for a part of a building, and when this part is done than a contract will be let out for another part of it, and so it goes, one part waiting upon another, instead of having a contract made such as can be made and such as is made by individuals and corporations in the construction of great buildings.

If there is not a change for the better, I shall insist that we devise some other plan of constructing public buildings than the plan we have pursued, which has proved such an ignominious and disgraceful failure.

Mr. Perkins—Mr. President, I wish to say one word in relation to the Supervising Architect; not to criticise civil-service reform or to criticise the qualifications of the Supervising Architect. I do not pretend to know anything about his qualifications, but it is the result to which I desire to direct attention. A tree is known by its wood or the fruit it bears.

Congress has appropriated a million and some odd hundred thousand dollars for a site for a building in the city and county of San Francisco. The building is to cost two or three million dollars or more. It is to contain the post-office, it is to hold the land office, the sub-treasury, the different courts of California, and the circuit court in that city. The building should be an ornament to the city and a credit to Government. The plans have been submitted to the judges who compose that circuit and judicial district, which embraces four States and three Territories. Their criticism of the plan is that it is not suited for the purpose of a court-room; that the library-room, the offices of the marshall, and the general arrangements of the building are such that they are not suitable to be occupied by our United States courts.

The plan was submitted to architects in San Francisco, and they revised it and made an estimate of the cost of changing the interior part of the building, and the estimate of its cost. This was submitted to the Supervising Architect in this city. He went over it and said he knew what they required better than the people did themselves. Yet these judges are appointed for life; they hold their positions, not as the result of civil-service examination but by reason of their judicial knowledge, by reason of their high character and standing as lawyers and citizens of the country. They

will now have jurisdiction of our new possessions in the Pacific Ocean, as well as of Alaska and Arizona, the States of Washington, Oregon and California. Yet the Supervising Architect, although they have sat upon the bench for years and years, say they do not know what kind of a court-room they should occupy: that they have no knowledge of the requirements of the jury-rooms, of the waiting-rooms, of the marshal's room or the library; but they must take this plan, the Architects says, without any back talk.

Our people felt so wrought up and indignant at this action that they have said: "We will ourselves raise a fund and donate it to the Government for the purpose of planning a building whose exterior shall be pleasing to the eye and which shall compare favorably with the private buildings erected by private capital in our city. We will have the plan so arranged—we will have the architect so arrange the different court-rooms that they will be acceptable to the judges, convenient to the jurors, and the litigants who there assemble from time to time to have their cases adjudicated." I have a picture of the building proposed, as it appears in the report of the Supervising Architect. I submit it to any impartial critic. I want to say parenthetically, although perhaps it is not necessary for me to say so, that I am not versed in architecture. Yet I know Grecian from Gothic; I know Byzantine from Moorish architecture; but I know, what is better than all, that which is agreeable and pleasing to the sight and the senses.

There are in San Francisco one thousands buildings whose exteriors, as compared with the proposed building, are as a painting by one of the masters compared to a chromo, and yet we must take this. We can appropriate the money for this purpose, but the building must be constructed against the protest of the judges of the court, against the protest of our people. The building must be thus constructed, and we must make appropriations for it, because the Supervising Architect, who has passed a civil-service examination, says he knows what we want.

Mr. Tillman—(examining picture.) Is this the picture of the building which the Senator from California has so eloquently described?

Mr. Perkins—That is the picture. It is the Supervising Architect's report.

Mr. Tillman—It looks like a cotton-factory.

Mr. Perkins—Our jail in San Francisco is a pleasant picture as compared with that. We have a half-dozen power-houses that generate power to run printing-presses more beautiful to the eye than that splendid picture here, submitted as a work of art by this architect.

I did not intend to say anything about this matter at the present time, as it is not the time or the occasion, but I could not resist, after hearing the remarks of my friend, the Senator from New Hampshire. At the proper time I shall propose that the people of San Francisco, public spirited as they are, may raise the money by public subscription to pay an architect—one of our architects in San Francisco, who has grown up from an office-boy to his present high position, and who has constructed some of those magnificent buildings—to design a building. The design shall not cost the Government a cent. I hope when the proper time comes that those of you who have looked at the picture of this beautiful structure will join me in saying that such a monstrosity shall not be erected in the great metropolis of the Pacific Coast, where the Pacific Ocean sings the sunset song of the nation.

Mr. Cullom—I hope the reading of the bill will be proceeded with. There is no amendment pending before the Senate.

Mr. Gorman—Mr. President, I have no word of criticism of the present occupant of the office of Supervising Architect of the Treasury. I know nothing of him. I take it for granted he is as competent a man as can be had for the compensation allowed for this office, $4500 per annum. I had nothing to do with the mode of his appointment and I have no criticism to make upon it. But I think it would be a wise and proper thing if Congress at this session were to increase the compensation of the Supervising Architect of the Treasury, and so enable the President or the Secretary of the Treasury, without regard to the technical examination by the Civil-Service Commission, to appoint a proper man to that position, with sufficient power to control his office. I see no reason why we should not do it. I believe in economy at the right place.

Mr. President, this bill bristles from the first chapter to the last with increased appropriations for clerks. How many new men are provided for I do not know, and I think it would be a very difficult matter for any Senator or member to ascertain just the number of small offices it is proposed to increase.

The organization of the office of the Supervising Architect has been imperfect for a long time. It is imperfect now. It stands with the second executive office in control held by a man whom the Secretary of the Treasury can not reach directly, nor can he select his successor without reference to examination.

I assert without fear of contradiction that there are but few men, sufficiently skilled, who would submit themselves to technical examination before the appointment was tendered to them. It is an embarrassment to the Government. I happen to be informed from some familiarity with that office, and I do not hesitate to say now, upon the floor of the Senate, that the may who is in charge of the executive branch of it—I do not mean the Architect, but his assistant—if he were in my employ, would not remain five minutes. Yet he is held there because he is under the civil service. That is one reason. There may be others of a general and political nature.

It is known to everybody that no such mismanagement has taken place in any other department of the Government. Yet in this very bill you have an extraordinary provision, such as ought not to be found in any appropriation bill for any of these offices. It provides that the expenditures on account of those who will be employed in providing plans and for the superintendence of these buildings shall be paid out of the general fund, the appropriation for public buildings not to exceed $200,000 per annum. It is a lump appropriation. It is true it is always provided that the Secretary of the Treasury shall, in his annual estimate, report to Congress the number of men and the compensation of the persons so employed. But that ought to be placed upon a business basis, as every other department of the Government is placed, making him estimate for the number of clerks, the number of draughtsmen, the number of engineers he desires to employ, and let us appropriate for them and place them all under the Secretary of the Treasury, and then hold him responsible for the work. . . .

Mr. Cullom—Mr. President, there is no amendment before the Senate, and I shall therefore say only a word. I appreciate the remarks of the Senator from Maryland, that when these appropriations are made it is difficult to cut them off, even after the occasion for them has in any degree passed away. The bill in many of its provisions has tried to anticipate the time when these extraordinary expenditures of money for clerks, etc., shall pass away. There are provisions limiting the approporiations to a given time. But we find ourselves involved in extra expenses on account of the war, on account of the general situation, which is new, and which we all hope, at least, will pass by in a very short time, when much of the expenditures provided for in the pending bill for clerk-hire and for other purposes to carry on the Government shall have passed away.

As to the Architect's office, we all agree that that has been badly managed and that there ought to be a new law providing for the conduct of that office and getting rid of the present mode of selecting the Architect I do not know who is in the office now, and if I have said anything which reflects upon any individual I hope it may be understood that I do not know the gentleman. I have had no occasion to have anything to do with the office during the present administration, or at least since a very short time after the administration came in, when I tried to bring about a general arrangement and secure the appointment of some man who would not have to go through a civil-service examination, because the very best architects in the country declined to do that.

Now, Mr. President, I hope the reading of the bill will be proceeded with.

Mr. Cockrell—In response to what the Senator from Illinois said, I will state that neither do I know the Supervising Architect. I do not even know his name. I do not know that I ever heard it.

Mr. Cullom—Nor I either.

Mr. Cockrell—What I have said has no reference to him personally, but it is to the system of administration that has existed there ever since I have known the office.

Mr. Cullum—That is my feeling about it.

Mr. Cockrell—It has been one continuous system, and no one has made any improvement upon it.—*Congressioual Record*.

TRADE NOTES.

A FINE half-tone plate, about 11x15½ in size, of the new Terminal Station at Boston, from a negative by Soderholtz, is being sent out to architects by Mr. Samuel Cabot of Boston. Interestiug statistics in regard to the building (which is the largest railway station in the world) are given, and attention called to the fact that 62,000 sqr. ft., of Cabot's Insulating Quilt were used to insulate the heating and veltilating ducts, under specification of Prof S. Homer Woodbridge, the expert, who has used the Quilt many times before in his work, notably the Rutland Hospital at Rutland, Mass., the Highschool at Newton, Mass., the Insane Hospital at Medfield, Mass., etc. The Quilt is made with or without the Asbestos covering and is a wonderfully efficient and cheap insulator and deadener; and it is claimed for the Asbestos Quilt that it is the only article made, which combines the qualities of a heat insulation, sound deadening and fireproofing.

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

PERSPECTIVE SKETCH, J. Murry, Architect.

INFORMATION CULLED FROM OUR EXCHANGES.

When the present growth of cypress timber is harvested that wood will practically disappear, for it is so extremely slow in maturing that there will be no second growth.

There are about 400 different species of so-called timber trees in the United States, but only about 20 of them attain commercial prominence, the rest being either too small or unfitted for commercial purposes, or consumed in small quantities for special uses.

The fact that the locust tree attains in 25 to 30 years the same thickness as the pine in 50 and the oak in 100 years, caused I. Kausch to conduct experiments with this variety of wood. The author gained the conviction that acacia wood has an important future, especially as regards its use for mining purposes. Acacia timber excels by great firmness and durability, and is, therefore, also well suited for many other purposes, such as wheels, bungs, ladder steps, etc. The locust tree thrives in the poorest soil, even in the rubbish of sandstone quarries and in slaty declivities. All that is necessary is to make a little hole in the latter, to fill it with mother soil, and to plant the young tree therein. In wet soil the locust tree does not thrive.

Many people think, says the *Canadian Trade Review*, that because there are dark streaks in maple flooring when it is first put down, that those dark streaks will remain to mar the floor. But this is an error. After the floor has been laid for a time and has frequently been scrubbed, as all maple floors usually are, the dark streaks are merged into the uniform light gray of the ordinary maple floor. Thus the appearance of a maple floor after it has been used for some time is very different from what it was when first put down.

In some cases architects have complained that where maple flooring has been specified the stock delivered was not all white lumber, and therefore should not be classed as clear flooring. They would have no trouble in securing such stock if the contractors were willing to pay the difference in price between that and the ordinary firsts and seconds. There are many dealers who make a separate grade of strictly white flooring and sell it at a price about $10 a thousand higher than that of the ordinary grade. But the clear white lumber must be treated differently from the ordinary run. It must be set on end and thus dried, because it will stick stain if dried in the common manner, and other precautions must be taken to protect it against stain.

In converting maple logs into lumber no great depth of cutting can be done before the saw runs into the heart. Even when the effort is to take off the white side clear of dark wood the saw is apt to run into the heart portion and streaks are left in the lumber. The most profitable way is to utilize all the log except the soft heart, which is worthless, and grade up the whole without reference to color. Then, if the manufacturer's trade requires all of the white flooring it can be selected out. One of the most prominent maple flooring concerns refuses to guarantee all white strips in its sales. Its first and second flooring includes both white and dark, with 50 per cent. of white as a general thing. On this basis large contracts are taken to supply office buildings, stores, public structures, etc., at the regular price of firsts and seconds. When such lumber is laid in floors the color becomes so nearly uniform in a short time that it gives entire satisfaction.

THE ADVANCEMENT OF PUBLIC TASTE IN ARCHITECTURE.

PAPER PRESENTED AT THE ELEVENTH CONVENTION OF THE ONTARIO ASSOCIATION OF ARCHITECTS.

BY MR. SIDDALL.

A FEW weeks ago Mr. Langton came to my office and asked for the title of the paper I was to read at the Conference this year. This was the first intimation I had received that a paper was expected from me. However, I believe it is the duty of every member of the society to do his share towards making our annual meeting a success, and although through want of leisure my attempt will not be of the value I would like it to be; I will not withhold it on that account, but give it for what it is worth.

A few days after the interview with Mr. Langton, I have just mentioned, I had the privilege of hearing the Rev. Mr. Shortt lecture to the Toronto Chapter, and he gave me the keynote for my remarks to-day in deploring the state of ignorance existing in the public mind regarding architecture, and suggesting that some method should be found and used, by architects, for its enlightenment. I therefore selected the subject you find on the agenda, "The advancement of Public Taste in Architecture." I will not, however, promise to stick very closely to my text, as I shall have, perhaps, quite as much to say about the taste of architects themselves.

The architect from the popular point of view is a pictorial artist on a large scale, and of all the arts his is the one most capable of prolonged effort in design, music and poetry coming next. Again the painter will produce pictures to frame and hang on a wall to be seen only by a chosen or limited number; a sculptor will adorn a pedestal with his effort, and only those who seek it find it; music and poetry reach an increased number, but architecture, as a decorative art, is seen by all men at all times, and its silent influence, consciously or unsciously, affects the minds of the cultured and uncultured.

To speak broadly, there are two faculties displayed in the architectural art—invention and imagination—one constructional and the other asthetic. Invention has to do with the plan and scheme of a building and the relationship of its parts—the artist calling this faculty into play in much the same way as the dramatist creates characters; disposes of their destinies; thinks out the course of events in his story, and sets the scenes. This can all be done by the faculty of invention. Having made the plan and settled the scheme of the structure, its heights and sizes, imagination does the rest, and clothes it with beauty. The construction will, of course, give the motive of the design. Every structural problem will be met and solved before the building is begun, and the architectural design keep pace step by step with the construction, partly modifying it and making it obedient to artistic consideration.

It is of the decorative or imaginative side of the art that I wish to speak—the side which appeals most to the public.

We are all the time seeing and handling things which are beautiful and give us pleasure, or ugly and give us pain. There is nothing, however, to compel us to look at poor pictures or distorted statues; but we cannot escape the ugly buildings which disfigure our streets. Nor can we prevent the baneful influence of such bad buildings on the minds of our children, who, unfortunately, grow familiar with them, and whose tastes will, in all probability, become as corrupt as those of the public to-day.

Considering then that architecture as a decorative art is so transcendently important, is it not astonishing that the bad architecture should have been so long a matter of indifference, or at any rate so long tolerated by the educated public?

The first question I ask therefore, and will endeavor to answer is—"How is the Public Taste to be trained to a better judgment in matters of architecture—a better appreciation of art—and taught to know good architectural design from bad"?

The first essential is, that the public shall be induced to take an interest in architecture, and shall be educated to do so. How is this to be achieved? Not so much by talking as by doing. Not so much by lectures and papers and art criticism as by our actual work in stone and brick and wood. By the quality of the art set before it will the public taste be healthy or unhealthy. It depends, therefore, upon the architects themselves in the greatest measure whether there shall be any advancement in the popular appreciation of our art.

The next essential is closer and more friendly relations between the public and the profession. While I don't agree that the feeling of contempt that is sometimes spoken of exists, except amongst the least thinking class, it is undoubtedly true that there could be a more mutual feeling of respect between them.

It is said that culture only means the development of new relations between ourselves and the world around us—a better understanding of how one things affects another. This can be made clear perhaps by imagining the way in which every individual would conduct himself towards the rest is a society of the highest possible culture. Courtesy would of course be the rule. Each person would recognize the welfare of the whole as of the utmost importance, and do all in his power to establish it. Nothing would be done in a spirit of selfishness or to draw attention. All would be in sympathy and work in harmony. Under conditions such as these architecture could attain to something like popular appreciation.

My second question is—"Are we architects going to work in the right way to produce the best of which we are capable, or are we working under hopeless conditions, which must prevent not only any originality, but even tolerably good work?"

Any art is valuable only so long as the artist can be seen in it. The inanimate material which the artist handles, be it a lump of clay, a stretch of canvas, or a heap of stones or bricks, is quickened into life by the artist's communication of his own spirit into the thing. I mean, of course, without pre-mediation, resulting in unconscious expression. We all know of some buildings which have been erected under conditions where the thought of the architect can be read, and his hand traced not only in the general design but in the minutest feature. Such buildings are interesting because they have character, and they owe it to the impress of the architect's personality on his work; and it is only such that can charm and interest the uneducated as well as the educated, and that really deserve the name of architecture.

In the middle ages very much was left to the trained workmen which the architect—or master builder—employed, but they worked under his personal direction, and he was always on the spot to tell them what to do and how to do it; and often himself worked with mallet and chisel on the sculpture which adorned the building.

If this supervision over every part of the building was necessary then, when the architect had under him a skilled body of artizans, trained to the methods of a single school: how much more necessary must it be at the present day when he has no such traditions? They have to work one week in one style and the next in another, and then probably in no style at all. No wonder they are hopelessly at sea when left to themselves. The architect of to-day should, therefore, think no part of his work too small for his attention; everything should be thought out, studied, and the smallest detail designed as carefully as the more important.

It is hardly necessary to say that this has not been done with a large proportion of the buildings in our cities. It is a melancholy fact that much that has been produced is either positively bad or absolutely uninteresting. The buildings

that are offensively bad are so from sheer ignorance or contempt for the recognized rules of art, and those that are dull and stupid often are so from the mere mechanical repetition of stock forms and stale ideas, which do duty for thought and save trouble of invention. With others truth has been sacrificed to whim, orders have been painfully caricatured, the details are inappropriate and often out of their proper position—a meaningless combination of forms, freaks and devices, dressed up to look fresh and clever. An uncultured and unappreciative public will call any extravagance fresh and clever until they are taught to know that there is a violation of some law. But the architect who does these things wins a cheap, but doubtful, reputation by pandering to a taste, which if he does not know is bad it is because his taste is no better than their own. He does not fear to blunder in his details, because he knows there is no one to detect them. His safety is in public ignorance.

How essentially different was it when the Greek architects were building. They were encouraged or admonished by the knowledge that they were watched by the trained and cultured eyes of all the Athenian people.

Every citizen was an intelligent critic. No Greek architect could deceive the public with a false proportion or vulgar profile; neither were they deceived by abundance of ornament covering a weak design. Nothing put purity and perfection obtained for the architect a reward. But when their high ideal of art was reached the appreciation and applause were promptly and ungrudgingly given and the reward—riches, honor and fame.

But alas for the architect to-day who is endowed with creative imagination and a keen sense of duty—whose profession is dear to him because of his love for his art. There is little in the condition of public sentiment from which he may draw inspiration and encouragement. He will see bad work pretty generally admired poor work too often approved.

I now come to the question, "Is not the public taste in Architecture retarded by a want of respect amongst architects for each other, and for which they are responsible more or less? I mean an absence of professional etiquette—the esprit-de-corps of other professions.

Sometime ago I read in a professional journal of an incident which occurred in the States and was singularly like one in which I was personally interested. A brother architect was in the witness box, having been called by the plaintiff to testify in certain points regarding professional charges. On cross-examination the opposing counsel asked "Is it not very common for architects to offer to submit plans on a venture, hoping that they may be accepted?" The question was objected to by the plaintiff's counsel, but the objection was not sustained by the judge, who remarked that the architectural profession was not like that of doctors or lawyers who never solicited work, but that it was well-known that architects were always glad to compete. The incident shows how little the architect's point of view is appreciated even by the educated portion of the community. But was it not to some extent true? The temptation to get work at any price is a constant one, and while the profession is open to any one, irrespective of ability, it is not strange that good and bad should be lumped together by the public in a single category.

It is true that there is a fundamental difference between the architectural profession and the others mentioned. A lawyer to practice must be a member of the Bar, the physician must have received his degree from the Medical University. The architect, however, is let loose upon the public with or without training. It is not to be expected then tha there shall be respect in the public for a profession which does not discriminate amongst its own members, and which is content to let its professional name be used by untrained individuals. Law and medicine have taken measures to protect the public from inefficiency. Architecture has not.

Another element in the want of appreciation of architecture as an art by the public is the established level charged for the services of all; the authoritive schedule of charges sanctioned by the mass of the profession.

The most carefully educated and gifted man gets no more for his services than an ignorant bungler. In other professions, such as music, painting, sculpture, medicine and law, artistic ability is so remunerated that there is always an incentive and opportunity for still further increase, and the public demand for a high artistic standard is established in these professions. It is evident that the value of the work of a true artist is greater than that of the man of small ability. Moreover, the system takes little account of the nature of the design and the amount of brain work required to produce it; the carefully studied and elaborate detail of a first-class residence is of no more value, judged by the existing standard, than the unadorned school house or barn.

A writer in one of the papers has summed up the question in these words—"By the present mode of payment the public first refuses to recognize the difference in the artistic capacity of individuals; second, it refuses to recognize the artistic difference in widely varying services rendered by the same individual; and, third, it refuses to pay the architect in a way that will enable him to give its work his best attention." But the strangest anomaly of all is, that the financial interests of the architect and his client are diametrically opposite. Take the case of a building of the normal value to say $50,000, the commission for which would be $2500. An architect unskilled and giving little thought to his work would probably spend $60,000 in carrying out the work, for which he would be paid a commission of $3000. Another architect by thought, labor and diligence, and making various studies and changes in his drawings is enabled to reduce the cost by $5000. His faithfulness and care are rewarded, not by extra payment for extra study and labor; he receives no payment at all for that, and the original commission is reduced by $250.00, 5 per cent on the amount saved for his client. The better he serves his client the more his commission is reduced.

To recapitulate and conclude, I would say, that before we architects accuse the public of being indifferent we shall do well to look at home and see whether the work we turn out has any real claim to be interesting, and before we claim that they do not know good work from bad, it is our business to ask ourselves whether we have given them a fair chance of seeing what good work is. We shall educate them to be critics by giving them good and faithful work as a standard by which to judge the qualify of the whole, and we can depend that every piece of really meritorious work will be an object lesson for the education of the popular taste and public appreciation.—*The Canadian Architect and Builder.*

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in one package, including all bolts and screws necessary.

See a full size working model at our store.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

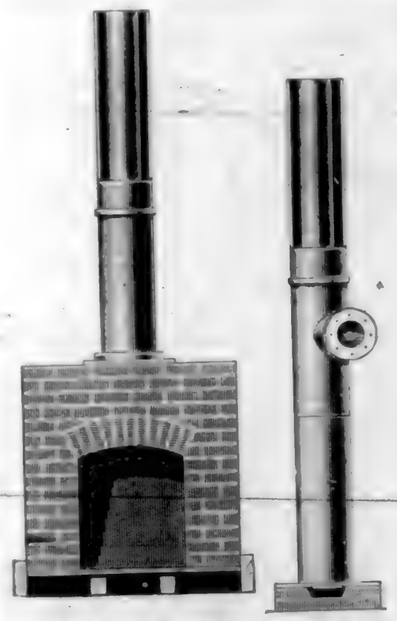
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257.

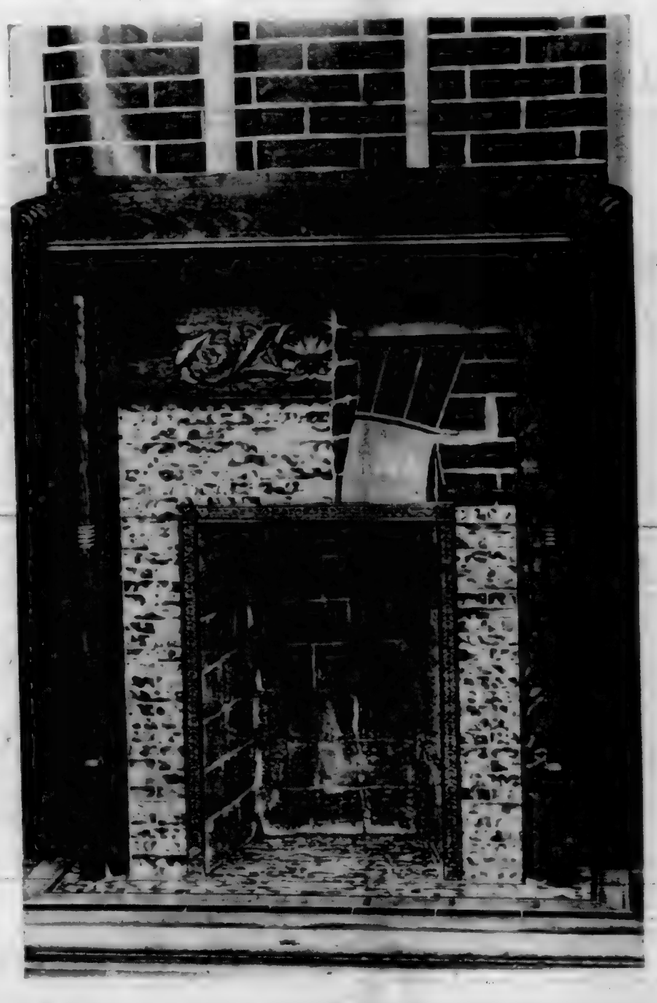
CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.



See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price, $2.50 for any size from 18 to 26 inches.

$5,000 Worth of Plans, Drawings and Details for Only $4.00.

Palliser's New Cottage Homes

With Detail Drawings.

The best, the largest and the most practical and complete work ever issued on plans of medium and low cost houses, containing one hundred and sixty new and original designs for cottages and villas, including every description of modern dwellings for the seaside, the south, winter and summer resorts, etc., double houses, country houses, city, suburban, town and city residences and apartment houses, of every kind and variety, in every conceivable combination of stone, brick, timber, plaster and frame costing from $75 to $7,000, giving all the comforts and conveniences, and suited to every taste, location, want, etc., also 50 new designs for city, brick block houses. The whole affecting the largest field of selection from the most approved and latest style of architecture. Illustrated by plans, elevations and perspective views from practical working drawings to a uniform scale, and not like the impractical sketch views which fill so many cheap architectural books that are in reality issued only as catalogues and price lists of printed plans. 1500 detail drawings covering the whole range of interior finishing and interior construction and arrangement of the plans in this work and all to a uniform large scale. Cabinet work of every description, mantels sideboards, bookcases, cabinets, dressers, etc., in almost endless numbers and variety. Stairs, hand railings, newels and balusters. Details will be found to cover every question that can arise in constructing dwellings of every kind. Fences, summer houses, pavilions, conservatories, arbors, well curbs, outbuildings, etc. Twelve new designs for stables and carriage houses, descriptive letter press, giving practical suggestions, cost, etc., which would alone fill an ordinary book of 150 pages. Details of furniture of every description, so plain that any good mechanic can understand and execute the same. Perspective views of four houses printed in colors, showing how to paint. Specifications and form of building contract, etc. The value of this work to builder cannot be estimated, as it contains plans and details for just such houses as they are called on to build every day. There is not a contractor or builder in the country that can afford to neglect this book. Building mechanics should all possess it. No matter what kind of a job they are called on to do, here are the ideas to help them out. Ideas are as necessary as tools and this work contains thousands of practical ideas. It is the educated mechanic that goes to the front every time. Prepared by PALLISER, PALLISER & CO., the well-known architects in one large volume 11x14 inches, printed on heavy cream paper, handsomely bound in boards and leather and sent to any address, on receipt of $1.00 by the

LACONIC PUBLISHING CO.,
123 Liberty St., N. Y.

Palliser's Useful Details

AN IMMENSE WORK

New Edition just published in paper portfolio, 14x22 inches, good paper and good prints. An entirely original and practical work that should be in the possession of every carpenter, builder, woodworker, stair builder, sash, blind and door maker, cabinet maker, mason and plasterer and all building mechanics. *The American Architect and Building News* says of this book: "We have often wondered that some American publishers did not undertake to produce such a book, for it has been evident that a large sale could be found for a work showing American constructive details of a good character, but at length has appeared just the work, and which has about it the indications of a useful and successful undertaking.

Useful to those who buy it and successful as a business adventure for the authors and publishers, grouped upon single folio sheets are a multitude of details well arranged and properly co-ordinated, of such constructive features as must be wrought into the small houses, stables, shops, etc., in which construction nine-tenths of the mechanics an a large proportion of the architects of this country find occupation. Useful details as they are properly called. When one sees the prodigality with which the authors have made publication of ideas, one cannot but smile afresh at the remark of a foreign architect "When I got an idea I wouldn't be giving it to the other fellows, I'd be keeping it for my own work."

Carpentry and Building remarks about "Useful Details": "The plates are large and withall are crowded, as though space were valuable. This is in one sense an advantage, since many more designs are obtained for the money expended.

We will send this great work, prepared by PALLISER, PALLISER & CO., the best known architects in the world, to any address, prepaid on receipt of only $2.00. Address all orders to

LACONIC PUBLISHING CO.,
123 Liberty St., N. Y.

Every Man a Complete Builder.

A $5.00 BOOK FOR ONLY $1.00

How to Build a House

Be your own architect

This book will save you hundreds of dollars. If you are thinking of building a house you ought to buy the new book PALLISER'S AMERICAN ARCHITECTURE; or, Every Man a Complete Builder, prepared by Palliser, Palliser & Co., the well-known architects.

There is not a builder, or anyone intending to build or otherwise interested, that can afford to be without it. It is a practical work, and the best, cheapest and most popular book ever issued on building. Nearly four hundred drawings. A $10 book in size and style, but we have determined to make it meet the popular demand to suit the times.

It contains 104 pages 11x14 inches in size, and consists of large 9x12 plate pages, giving plans, elevations, perspective views, descriptions, owners' names, actual cost of construction, so-to-speak work, and instructions How to Build, 70 cottages, villas, double houses brick block houses, suitable for city suburbs, town and country, and costing from $800 to $6500; also barns, stables, school houses, town halls, churches and other public buildings, selection of site, employment of architects. It is worth $5 to anyone, but we will send it in paper cover by mail, postpaid, on receipt of $1.00; bound in cloth, $2.00. Address all orders to

Twenty-third Ave. near Pt. Lobos. To build; o, W. A. Deane; c, E. C. Blaisdell; c, E. C. Bletch; cost $3979.

Waller near Primrose. Four two-story frames; o, F. Nelson; cost $20,000.

Washington and Laguna. Excavation; c, Wm. G. Irwin; a, Reid Bros; c, Gray Bros; signed, May 8; filed, May 20; cost $8200. Cast and wrought iron; c, Judson M'f'g. Co; cost $11,277.

Webster near Filbert. To build; o, A. J. Kennedy; a, M. J. Bugbee; c, E. A. McCarthy; cost $2200.

Union near Octavia. To build; o, Johanna Slattery; a, J. P. Dunn; c, Douglass & Campbell; cost $3175.

Vallejo near Octavia. Carpentry etc; o, Joseph Goetz; c, Wm. Plant; cost $8825. Plumbing, etc c, J. E. Britt; cost $1990.

Van Ness and Union. To build; o, Mrs. Antonio F Bendmann; a, M. J. Lyon; c, G. Roberts Elder; cost $3350.

The Yale & Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key, afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," the range of products and grades is such as to meet conditions where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

GENERAL OFFICES:

Nos. 9, 11 and 13 Murray Street, New York City.

WEBSTER'S INTERNATIONAL DICTIONARY

LEARN TO STUFF BIRDS! LEARN TAXIDERMY! LEARN TO-DAY!

Because success is guaranteed from the start! Because the work is pleasant as well as profitable. A collection of birds is both beautiful and valuable. Birds, animals, fish, reptiles, etc., may be preserved with little trouble, as records of the day's chase.

Boys, girls, men and women can do nice work from the start, and can become expert in one week. Mounted birds find a ready sale; besides you can make money teaching your friends. Every school should have a collection of native birds and animals.

TAXIDER is a compound of wonderful embalming power. It is not necessary to skin birds or animals when using Taxider. Birds when mounted with Taxider become as hard as stone, and will last a thousand years undisturbed by moth or time. No tools required except those that everyone has. One box Taxider is enough to mount 30 birds the size of a quail, with full instructions for mounting everything. Also instructions for tanning skins for rugs, etc. Price $1.

SEE WHAT ONE MAN SAYS

TACOMA, Wash., Aug. 9, 1898.—Mr. F. L. Ackley: I received the box of Taxider some time ago. It works fine. I have just finished mounting a beautiful swan. I have already a nice collection of birds, and a class of seven boys. It is really wonderful how it works. The very first bird I mounted was a success. Please find enclosed money order for one dozen boxes. Please rush, as I am in quite a hurry. Thanking you for past favors,

I remain truly yours, J. H. FLANDERS, Tacoma, Wash.

I have letters like this from hundreds of people, and all are having success. Send for a box to-day. You can learn in one hour. Remember, success is guaranteed from the start. Liberal discounts to agents. Taxider is manufactured by **F. L. ACKLEY, Sioux City, Ia., U. S. A.**

A MONTHLY JOURNAL DEVOTED TO THE ARCHITECTURAL INTERESTS OF THE PACIFIC COAST.

CAUTION—Pay no money to persons representing themselves to be connected with the CALIFORNIA ARCHITECT AND BUILDING NEWS unless a written authority to receipt for the same is shown and accept no receipt unless it be on our printed blanks. All Checks and Drafts are to be made payable to the order of E. H. Burrell.

TO THE critical judgment nothing is more offensive than the positive, pretentious and false in art. A small boy may show us his drawing of a horse, expecting commendation, which we give, in a degree, because the work has some merit as the attempt of an untutored child. But when a man of mature years presents us a Rosinante on canvass as a work of art, we feel an impulse to devote it to the flames. The fact that the author of the work has so poor an opinion of our taste and judgment as to attempt to impose upon us, arouses our resentment. His reputation as an impostor is at once established, and although he may afterwards produce a fairly creditable work, we regard him with suspicion.

Hence a house painter, or a man who decorates furniture, carriages and steamboats may not assume to belong to that profession which furnishes pictures for the art institute or the salon. If he is a good house painter or decorator, let him be satisfied to be that. If a stone cutter can hew out architectural details in stone, according to the design furnished him, let him do that as perfectly as he can, but not call himself a sculptor. In doing his own work well lies the true distinction.

One may read, in a by-street of an eastern city, on a swinging sign, this legend: "Professor of Whitewashing." Of course the professor is a colored individual whose ambition is to be above his humble calling. But however we may sympathize with his aspirations, we are forced to smile at the vanity which prompted the title he has given himself.

In the case of the professor of whitewashing no harm is done, because nobody is deceived. It is a different proposition when men who have no right to call themselves architects go about the streets of San Francisco spying out contemplated improvements, and offering building plans which they too frequently get accepted because of their alleged economy.

A man is not an architect who . only a carpenter or a

builder. It is true that he must thoroughly understand the *principles* of carpentry and building, and the various ways and methods of their application in the practice of his profession, in order to be an architect in the proper sense; but to these must be added scientific knowledge, and the artistic quality of brai With all these, and an honest intention to apply them for the benefit of his clients, for a reasonable amount of pay, he may be permitted to make contracts.

There is a great deal of false economy practiced by property owners in this city, by which the tenant class of householders and others suffer damage. In the first place there is the cheap "architect." He brings in the cheap contractor. They stand in together. A house is quickly built, for a seemingly low price, but in such a way as to leave a good margin of profit for the contractor. The lumber in it would hardly make a respectable woodpile for a New England household during a New England winter.

The walls of the structure are scarcely thicker than a packing-box. The floors are faulty, the stairs creak, the flues are unsafe, the plumbing is bad, the plaster cracks, and, in fact, the whole thing is a miserable pretense. But when the owner first sees his completed house, in all the glory of newness, before winds or earthquakes have shaken it, before sun and sand have defaced it, before it has shrunken, twisted, faded, grown old, he looks upon this creation with much satisfaction. Not being an architect, nor even a carpenter, he does not at first detect the fraud. The sense of being cheated comes, however in a very few years, if not in a few months. Tenants are always asking for repairs, and moving to newer houses. If he is unlucky enough to own several of these tenements in a row, he has the pleasure of seeing the windows placarded with TO LET month after month, until he is tempted to join the street urchins in stoning them. In vain he ponders on the problem of how to get interest on the value of his real estate. The longer his houses are empty the less willing is he to tempt renters by lowering the rent. He says he cannot afford it.

There are two factors entering into this condition of the property owner's mind. The first is the excessive value put upon ground in San Francisco; the second the cheapness of the buildings erected upon the high priced ground. The value of the ground increases, or should do so, while the value of the improvements rapidly decreases, and the joint value is not sustained. Neither can it be restored, except by tearing down, and building up again.

No city in the United States of the size of San Francisco shows so many vacant houses. The impression it gives the passing observer is that the population is growing less. This is not, however, the case. The vacancies occur chiefly from the inferior character of the houses that are built to let. The new houses are taken as soon as completed, and in a few years are in turn deserted. There is, all around, room for reform in business methods. Let us have it.

THEN AND NOW IN ARCHITECTURE.

PLACES of religious worship have in every country led the architectural idea. The temples of Egypt, India, Persia, Assyria, Greece, Rome, were the structures on which the genius and the wealth of these countries were lavished. Palaces or government buildings came next in importance, not only because kings, princes and captains were possessed of great wealth, but because in ancient times these persons were revered as half divine—demigods—and entitled to honors next to the supreme deity. Tombs of great men for the same reason were made costly, and as nearly imperishable as possible—they contained the mummies or the ashes of sacred personages.

Imitation led to the adoption of certain adaptable features of public buildings in private houses; hence the use of columns, which we have seen was the foundation of all the ancient "orders". The destruction which fell upon ancient Rome left only a few ruins as examples of its architectural achievements. The removal of the capital to Byzantium, and the introduction of Oriental ideas even into the Christian religion, which Constantine had forced upon the people, had a tendency to obliterate something of the past, while it had not strength enough to substitute any very positive features in place of those that were lost.

Rome for centuries after Christianity was nominally accepted as the religion of the people, was still pagan in sentiment, as her thousands of Christian martyrs give evidence. Not until the eighth century did the Church have strength enough to possess itself of temporal rule, and thus secure an opportunity to revive theocracy in a new form. With that revival came the necessity for Christian temples, or churches. Naturally the earliest Christian architecture was a modified, and often a very meager form of the older Roman. In fact the first public places of worship were pagan temples despoiled of their magnificence, as the Pantheon.

But before this period, while Christians were suffering persecutions which prohibited public worship, certain architectural ideas became fixed in their minds, which govern church architecture to this day. Their root was in the Egyptian temple, which had the portico, the vestibule, the cella, and at the end another more sacred enclosure. The Greeks had the same gradual approach to the mysteries, although their columns were outside, instead of inside the walls. The Romans, as has been shown, retained this idea in their public halls, or basilicas, even to having at the end a semi-circular apse behind a row of columns. This was used by the magistrates for hearing complaints. Even a Roman dwelling had its columned portico and hall, beyond which were the private apartments.

Therefore, whether it was the basilica or the private residence, in which the persecuted Christians first held religious services, that was imitated in the earliest churches, it clearly is still the inside form of our church edifices from the simple village structure to the grandest cathedral. To the long straight hall, growing darker as it was more deeply penetrated, there have been added side aisles, with apses, and niches to accommodate statues, with other modifications; but the Egyptian, Grecian and Roman model of temple-building, with the sacred enclosure from which the worshipper was excluded, remains to us.

The mediæval period showed a transition from classicism evidently experimental, as when the basilica form was raised to two or three stories, each narrower than the other until the uppermost elevation became insignificant, and the whole outline unpleasing. Buttresses were developed from the Greek pilaster, being merely a thickening of the flat wall at points where greater strength was required. The tendency to accentuate upward lines instead of horizontal ones gave a different character to buildings, and the introduction of windows as a feature, were all innovations which produced a style called Romanesque, or early Gothic (on account of its rudeness) but out of which the perfected Gothic in the course of half a dozen centuries was evolved.

A STUDY

Columns, as the change progressed, became adjuncts to instead of the main features of a building. While they still occupied their former position as supports to the roof of a portico, they were replaced in the walls by flying buttresses used to resist the pressure of the roofing, and on the inside were employed as the base from which sprang arches of nave and transept, or the supports of the dome itself. They divided the interior of churches into three aisles, and formed colonnades in lateral projections adding grandeur but not mystery to the sacred place. Domed roofs, high arched windows, lofty bell towers and great size united to impress the beholder.

But all these were simply the back ground on which, in the Renaissance of the arts, painting and sculpture, with mosaic and bronze work, were employed. Inside and outside, churches were decorated with a richness wonderful and worthy of admiration, if not in every instance in correct taste. The guild of masons was granted by the Popes special priveleges and exceptions on account of their importance in church architecture. Artists of every guild received high honors and rich rewards. The treasure of all Europe was at the disposal of the church. Cities rivalled each other in patronizing art, and princes surrounded themselves with scholars and men of genius.

To this sunburst of imagination and learning the Crusades

had contributed not a little. Religion, romance, adventure had given life to the germs of intellectual activity which during the many centuries of mental darkness in Europe had lain dormant. From the Orient the fittest to survive returned with new knowledge. Those who had gone simply as mendicant pilgrims perished by thousands. Others who remained a home, in the absence of their feudal lords learned to become their own masters, and although the wealth which was brought back went chiefly into the coffers of the church, it was the Crusades that first lifted the yoke of surfdom from the neck of darkened Europe, and gave a fresh impulse to civilization.

Not only was Rome awakened to new life, but many cities of southern Europe, Venice, Pisa, Sienna, Perugia, Florence and Milan, in Italy, with others in France, Spain, Germany and England strove together for five centuries to discover new styles which should combine the religious sentiment with grandeur and beauty in the most perfect form.

The trade of the Mediterranean cities with the east, the invasion of Spain by the Saracens, the study of the remains of classic art all contributed to the development and completeness of the Gothic style. In this pursuit the suggestions of climate are plainly evident, the more northern countries contributing to Gothic architecture a greater slant in the roof with more projecting cornices, and more projecting buttresses than were thought necessary in the south of Europe. Also the sculptures used as architectural features had a character of their own, as different as the legends of the early northern writers are different from the classic poetry of Greece and Rome. Despite these characteristics the architectural idea continued to soar heavenward on lines of ever increasing beauty until there seemed nothing left, in some instances, to be desired.

The clever critic, however, who approaches St. Peters at Rome, so commonly regarded as the show church of the world, soon becomes sensible of a defect in its proportions. The designer had not sufficiently studied perspective and proportion to give the beholder a true idea of its great size, or even a magnified one, which would be better. There is nothing with which to compare it, or scale by which to measure it, and it becomes commonplace by looking like a smaller building seen through a spectroscope. The rule in Gothic architecture is the height of a man multiplied, not exaggerated. It is this careful study of proportion, both real and seeming, which constituted the charm of Grecian art.

The interior of the St. Peters has the fault just referred to, the paintings upon the dome being of special scriptural subjects, whereas at such a distance from the eye they should be of a decorative style only, and simple for effect as ornament, while the coloring should be so delicate as to increase the apparent height instead of lowering it, as very strong colors would do. But even Micheal Angelo had some things to learn; and besides, his patrons required scriptural subjects visibly portrayed.

But the glory of St. Peters was the successful erection of so vast a dome, the effect of which was afterwards lessened by the lengthening of the nave, causing it to sink, apparently, as the structure is approached from the west front. With its magnificence in size, in decoration, in art treasures, and material wealth, to which each one of the long succession of Popes has added something, St. Peters may well be regarded as an architectural wonder, the rival to which our age is not likely to produce, because the conditions can never again be the same that they were from the eighth to the sixteenth centuries.

As a matter of fact, Italy never fully adopted the pointed Gothic style, although it is found with modified features in such structures as the cathedrals at Florence, Sienna and Milan. The latter, indeed, is architecturally faulty, being impressive chiefly on account of its size and its richness of ornament rather than its design. The Gothic period ended with the beginning of the Renaissance in the thirteenth century, but it is to the monuments constructed during its continuance that we turn with most interest. It is the history of architectural experiment carried on for a thousand years, and under many hampering vicissitudes. It shows us combinations which, if lacking in classic simplicity and elegance, suggest strength, invention, sentiment, and achievement lacking in this our age.

Although the germ of the ancient temple, as has been stated, had been preserved in the portico, the columned aisle, and the apse at the *east* end of the aisle (an Oriental idea) the change in religion in the Christian period called for changes in the interior and exterior arrangement of churches which gave great scope to all the arts. The campanile or bell-tower, and the baptistery were usually seperate structures, treated often in a style quite different from the church. The pulpit and the choir afforded opportunities for the employment of original designs, both by architects and sculptors. Upon these features were lavished years of labor and large sums of money.

Taking for example the pulpit of the baptistery at Pisa in Italy, executed in the latter half of the thirteenth century: It is of marble in a hexagonal form, supported upon seven pillars, while two more support the staircase. Three of the columns rest upon figures of lions with smaller animals in their claws. Three animal figures, a lion, a tiger and a griffin support the central column, and at the foot of the stairs is the recumbent figure of a lion. The shafts of five of the main columns are of different kinds of granite, while the two under the stairs are of Parian marble, and two others are of Sicilian jasper and brocatello. There are two desks so placed as to constitute ornamental features. Above the columns are allegorical figures of Prophets and Evangelists. There are, carved in relief upon the five sides of the pulpit, scenes from the Annunciation, the birth of Christ, the Adoration of the Kings, the Presentation in the Temple, the Crucifixion and Last Judgement.

All this suggests the early Pagan idea of ornamentation, which indeed it resembled, the details being brought out with painful minuteness, black paste being used to accentuate the pupils of the eyes, the cavities of the nostrils and ears, and the lines about the lips. The hair and ornaments were gilded, and the figures all in such high relief as to be very nearly detached.

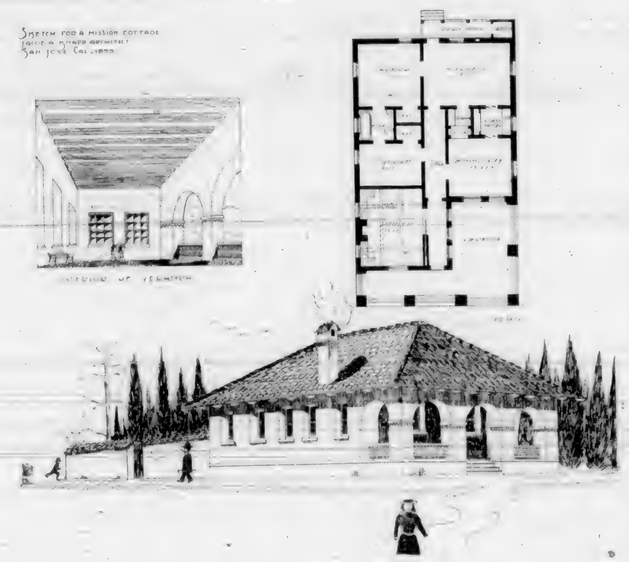
It has been remarked concerning this work that the figures are two grand and noble for the proper representation of such scenes, which called for tenderness and humility. The explanation is to be found in the fact that the artist, who was also the architect, had studied the Roman antiques. The same artist being called upon to invent devils to suit the popular notion of Satan and his imps, made them with repulsively grotesque head and features, the body and claws of a vulture, joined to the legs of an ox. Such was the luxuriance of the mediæval imagination applied to church building, both inside and outside.

All the most famous cathedrals of Europe are restorations of the earlier Christian churches, as, for instance, that of Milan, so celebrated by writers of books of travel. The name of its original architect is not known, but the architect

who undertook its reconstruction, in 1386, was an Italian Giam Galeazzo Viconti. The work proceeded slowly, notwithstanding that masons were called from Germany to assist in it.

It was not finally completed until 1805. The form is that of a cross, the length four hundred and seventy-seven feet, with a width of one hundred and eighty-three feet. The height of the nave is one hundred and fifty-five feet, that of the cupola two hundred and twenty-six, and of the tower three hundred and sixty feet.

A work done by so many masters could not have a perfect



purity of style. The Gothic style of the first intent is destroyed by Romanesque windows, portals, and other features. The interior has two aisles, and there are aisles in the transepts. The roof is supported by fifty-two columns, with canopied niches for statues in place of capitals. The painted glass windows of the apse are very brilliant; the carvings are elaborate; there are hundreds of colossal statues upon the cornice, roof and various projections, all of which, together with the immensity of the white marble pile form an object bewildering as captivating to the beholder. But the Cathedral of Milan cannot be said to have a distinct place in the history of architecture.

Rome had converted basilicas into churches. In the beginning of the fourteenth century Florence converted a market place into the church of Or San Michele, the artist taking eleven years to complete the change. A shrine to the Virgin was erected in the form of a Gothic pyramid, of white marble, which rose nearly to the roof, and was beautifully proportioned. The life of the Virgin is illustrated in nine scenes in bas-relief, two upon each face of the basement, and the ninth, a large scene, covering the back of the tabernacle or shrine. All the work is graceful and refined, including the beautiful statuettes and the clustered columns and pinnacles. Its rich mosaics and exquisite finish make good its claim to be called the "Jewel of Italy." Its cost was eighty-six thousand gold florins—money that had been poured into the treasury of the church during the prevalence of the plague of 1348, when miracles were worked by the shrine of the Virgin.

In the beginning of the fifteenth century there was a meeting of engineers at Florence, competing for the acceptance of plans for raising the cupola of the Cathedral San Marcia del Fiori, the largest dome, measured diametrically, in the world. The work was entrusted to architect Filippo Brunellesco, who was also a sculptor. It was of an excellence of construction that has never been surpassed, but Michael Angelo, who greatly admired it, made the dome of St. Peters to excel it in beauty

Branellesco had much to do with the Renaissance or rebuilding period of architecture in Italy. He rebuilt the church of San Lorenzo at Florence, and built the church of Santo Spirito, the interior of which is in his best style. He was one of the competitors for the honor of designing the second bronze door of the Baptistry at Florence which was secured by Lorenzo Ghiberti, and begun in 1403, and which has been the admiration of the world for four and a half centuries, as it must continue to be for all time.

Turning from churches to palaces, Brunellesco designed the Pitti Palace, at Florence, which is among the earliest efforts of the Renaissance in this branch of architecture. It is monumental in grandeur, with a facade four hundred and sixty feet in length, of three stories, each forty feet in height, and built of undressed stone, or fragments of rock rugged and dark. Immense round arcades support the windows, and a simple balustrade runs along the top of the wall. No attempt is made to imitate any order.

Some reason other than indifference to architectural effects should be looked for in accounting for the bestowal of all the arts could bring to beautify churches, while the residences of princes were still rude in construction. That reason was probably to be found in the fact that churches were places of sanctuary, where life and treasure were safe from foes or plunderers, while palaces in the frequent wars between neighboring states were points of attack. Gradually as civilization developed the reign of peace, the embellishment of dwellings amplified, and there arose in the sixteenth century many instances of the genius of the age applied to the homes of the rich and powerful.

The farther from Rome we pursue the subject, the more we find of originality of fancy in combinations of styles. From Venice to London, through France, Spain and Germany, there occur continually new features. The Romans adhered more or less tenaciously to the classic, or ancient Roman models. Florence violated this classic idea by superimposing several stories of columns supported by cornices, with arched windows between, in flat walls. Venice hung balconies and oriels out from her windows, and was profuse in wall decorations, both as to design and color, using different marbles to produce effects. The French built their chateaux with round towers at the angles and steep roofs, dormer windows in the upper story continuing the architectural design above the cornice; while their town houses made up for this simplicity by a confusion of orders and details which, while not strictly correct, were undeniably picturesque.

England had less to do with the Renaissance than continental Europe. What corresponds to it, known as the Elizabethan period, is really the perfection of the Gothic style of which England furnishes the finest examples, St. Paul's in London being the chief. About the middle of the seventeenth century the restoration of the old St. Paul's church was projected, and undertaken by Sir Christopher Wren, who promised to remodel it "after a good Roman manner," and also not "to follow the Gothic rudeness of the old design." In the same year, however, London was burned, and only a portion of the walls of St. Paul's left standing.

Two or three years afterwards Wren was again commissioned to execute the rebuilding of the church. His first plan had too many features of the "Roman manner" to please the dean and chapter, and another was substituted in which the architect finally modified and improved upon the former ones, the result being the present St. Paul's, whose symmetry is unrivalled by any Gothic structure in Europe. He overcame the defect in St. Peter's of the apparent sinking of the dome, by placing a second external higher dome of wood over the internal one, thus preserving the interior proportion while giving the necessary elevation on the outside. By an ingenious device he furnished odequate support to the stone lantern surmounting the dome, which gives the effect of great elevation to the structure.

Wren rebuilt several of the many churches destroyed by the great fire, besides designing numerous public buildings in London and elsewhere. His genius is impressed indelibly upon English architecture.

Germany was less affected by the revival of art than was England. Spain was subject to such conditions, through the influence of the Moorish spirit, as to take it out of the category of the countries prompted by the Renaissance spirit. Of the great buildings erected during this period the most noted are St. Peters in Italy, the Escurial in Spain, Versailles in France and St. Paul's in London. In contemplating its glorious achievements the student of architecture must be reverently impressed with the power of the human intellect, and be led to ask himself, "What of the future?"

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

WORK has commenced on the third $60,000 structure to be built this year in San Francisco. It will be erected by Frederick Kronenberg on the northeast corner of McAllister and Franklin streets, and will cover an area of 137:6x120 feet. The main front will be on McAllister street, where five stores will be situated on the ground floor with rooms in the rear. Above will be sixteen flats, access to which will be by means of ten tiled vestibules so arranged that each apartment will have its separate entrance. The construction will be of the most modern character and the interior appointments will be of the most convenient kind. In addition to the main building a smaller one containing four flats will be placed on the end of the lot facing on Locust avenue. Salfield & Kohlberg are the architects of the Kronenberg building.

THE REAPER CLAIMS A PIONEER ARCHITECT.

WILLIAM PATTON DIES AT HIS HOME IN ALAMEDA.

WILLIAM PATTON, one of the pioneer architects of the Pacific Coast, who designed a portion of San Francisco's new City Hall, died this month at his home, 2253 Central avenue, Alameda. He had been ill for a number of months, suffering from cancer of the throat, and his death had been expected daily. Deceased was a native of Sunderland, England, aged 78 years. When a boy he entered an architect's office and served his apprenticement. When news of the gold discoveries in California reached the old country he was among the first to start for the new El Dorado.

After passing several years in the mines, Mr. Patton returned to San Francisco and opened an architects office on Washington street, where he followed his profession with great success and amassed a fortune, part of which, however, was lost in late years by unprofitable speculation. Mr. Patton married in San Francisco. About twenty years ago he built his home at 2253 Central avenue and took up his residence in Alameda.

Many of San Francisco's early landmarks were designed by Mr. Patton. Some of them have since been torn down, while others are still standing monuments to the architect's skill. He was a member of the San Francisco Chapter of the American Institute of Architects. Among the San Francisco buildings designed by him are the Sutter street Synagogue, the Safe Deposit building, Donahue block, Mission and Fremont streets; the old Star King church, since replaced by the new structure; the old Chronicle building, Bush and Kearny streets, and the Alcazar building. He was supervising architect of the new City Hall, and designer of the northwest and northeast wings, the City Prison and the Hall of Records. Many of the finest buildings in Alameda were also designed by him.

Mrs. Patton died about fourteen years ago. Two sons, William and Clarence, survive the father. Deceased was a member of the Society of California Pioneer. The funeral services will be held under the auspices of the society.

A MAMMOTH BLOCK OF STONE.

THE SOUTHERN Marble Company, of Marble Hill, Ga., has won the distinction of taking from its quarries in Pickens County one of the largest blocks of marble that has been quarried in the world dcring modern times. The marble was taken out last month, and has been shipped north for use in one of the contracts of the great firm of Norcross Brothers.

The block of marble is almost pure white and measures 27 feet 2 inches long by 4 feet 3 inches wide, having in all the mass 500 cubic feet.

The officials of the company are proud of the fact that the block was removed after careful labor without a break, as it is considered very difficult to remove such a mass without some accident happening to it in the process of removal from the quarry.

The exact weight of the block, according to the statement of the manager of the company, is 100,066 pounds, requiring an immense amount of labor to finally place it on board the car for its journey to the north.

The next largest block of marble ever taken out of a quarry in Georgia was on exhibition at the Cotton States and International Exposition and weighed only 45,200 pounds, or less than half of the weight of the monstrous block taken out last week.

Notice of the removal of the monster monolith was sent to Professor Yeates, of the Geological Survey, and a photograph of the block, just befor it was put upon the cars, will be placed in the permanent exhibit of the survey.—*Stone.*

NOTICE OF MEETINGS.

SAN FRANCISCO CHAPTER, AMERICAN INSTITUTE OF ARCHITECTS, meets second Friday of each month at 408 California street, at 4 p. m.

SETH BABSON, Pres. — H. A. SCHULTZ, Vice-Pres.
J. W. REID, Sec. — JOHN M. CURTIS, Treas.

SOUTHERN CALIFORNIA CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

A. B. BENTON, PRES. — ARTHUR B. BENTON, Vice-Pres.
JOHN P. KREMPEL, Sec't. — AUGUST WACKERBARTH, Treas.

WASHINGTON CHAPTER AMERICAN INSTITUTE OF ARCHITECTS, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

JOS. C. HORNBLOWER, Pres. — JAS. G. HILL, Vice-Pres.
E. W. DUNN, JR., Sec. — W. J. MARSH, Treas.

ASSOCIATION OF ARCHITECTS OF ARIZONA, meetings held at Phoenix, Arizona.

D. W. MILLARD, Pres. — T. H. MADDOX, Vice-Pres.
W. R. NORTON, Sec. and Treas.

TECHNICAL SOCIETY OF THE PACIFIC COAST, meets first Friday of each month at Academy of Sciences Building.

GEO. W. PERCY, Pres. — W. F. C. HASSON, Vice-Pres.
OTTO VON GELDERN, Sec. — EDWARD T. SCHILD, Treas.

MASTER PLUMBERS' ASSOCIATION, meets every first and third Friday of each month at the Flood Building.

JAS. E. BRITT, Pres. — J. L. E. Firman, Sec.

BUILDERS' EXCHANGE, Directors meet first Friday in each month at Mission and New Montgomery.

S. H. KENT, Pres. — JAS. A. WILSON, Sec.

MASONS' AND BUILDERS' ASSOCIATION, meet first Friday evening of each month.

ADAM BECK, Pres. — M. V. BRADY, Sec.

ANCIENT AND MODERN BUILDING IN PALESTINE.

AT A meeting of the English Architectural Association in January, Mr. Beresford Pite gave an illustrated lecture on this subject.

Mr. Pite declared that it would be impossible for him to cover the subject with any thoroughness in one lecture, and he could only relate what struck him most forcibly when he visited Palestine. The lecturer then showed how the architectural interests of Palestine began with caves and rock tombs, cisterns and oil and wine presses, and then the buildings. The variety of influences which passed over the land in its early history had its effect on the people and their work. Beginning with Egyptian influence, they came to periods when Phœnician, Assyrian, Græco-Roman and Roman styles could be traced. Then the history of the country became obscure as they passed through dark ages to the Arab period. The years of crusading followed, dotting Palestine with interesting examples of Mediæval art. Turkish sway, too, had left its memorials, and as landmarks of modern work and travel some buildings presented the strong characteristics of the Gothic Revival. Apart from the artistic and historic periods there was the material to be considered. The building material most ready to hand was a hard limestone, difficult to work and offering little opportunity for ornamentation. The soil of the land was poor and yielded but scanty crops of coarse grain, so that when seeking to copy from nature the native imitated the heaviness of his surroundings. The country was also the seat of endless wars and disasters, so that durability and not beauty was the great aim of those engaged in architecture. The lecturer then gave some practical hints to those who might have to design for buildings in Palestine. The consideration of aspect was most important. It was always well to avoid an eastern aspect, and near Jerusalem itself it was advisable to turn the building away from the road because of the quantity of dust, which was terrible during the hot months when there was a drought of water. There were only two wells in Jerusalem, and the city was wholly dependent on the rain fall for its supply of water. In the absence, therefore, of a water supply the cost of water had to be seriously considered. If water ran out during building operations it meant an increase in the cost of construction. It was, therefore, necessary to begin building operations by constructing and excavating a cistern for the season's rainfall, thus providing against the drought which would certainly arise during the hottest months. There was an absence of any system of drainage, and no kind of cesspit could be properly adopted because of the hardness of the rock and the small depth of earth which covered it.

When designing a building the arrangements for heating had hardly to be considered. Fireplaces resembling those of the Western nations were not generally used. In buildings established for the protection of Russian subjects Mr. Pite said he noticed more attention had been paid to the heating of the building, and stoves had often been adopted. The carriage of materials was a most important item when doing work in the East. The railway could only carry coal, so that it was impossible to send up heavy material in large quantities. Camels were the beasts of burden. In order that foreigners might erect a building of any size a royal fireman from Constantinople was necessary, and even when this Imperial permission had been obtained the local authorities had to be pacified and a liberal amount of backshish expended before operations could be commenced. If mosques were in the vicinity of the site the permission was more difficult to obtain, the religious traditions and superstitions of the case bearing an important part in the negotiations. There seemed to be no builder, and consequently no contractor, in Jerusalem; but still the lecturer, with the assistance of a German architect resident in Jerusalem, had overcome such difficulties. Plans made in London had been carried out with the utmost accuracy. The workmen would only recognize one master, and thus the man who gave the orders must also have the paying of the men engaged on the job. There was an entire absence of sand for building purposes, but a good supply of lime was to be obtained.

Mr. Pite then gave a list of the prices charged for work in Jerusalem:

Roofing.—Tiles came from Marseilles and cost 25 francs per 1,000. The work was wired to battens; rewiring was necessary every ten years.

Bricks.—The best were foreign, the native ones were worth nothing. Bricks cost from 7 to 12 francs per 100 (*i. e.*, 4*d.* to 5*d.* per 1000).

Paving Tiles cost from 6 to 8 francs per square metre.

Timber.—About five times the cost paid at home.

Building cost for cubing about 12 francs per cubic metre, about 10 francs for foundations, and cisterns 10 francs.

Lime costs about one-twelfth of whole buildings; lime costs about one-fifth of cost of wall, including probably plastering; for girls' school (not plastered), one-seventh to one-eighth.

Walling.—Stones for inner side 1 piastre each, for outer side, hewn, 2 piastres each. Lime, 5 to 6 piastres. Wages and hauling, 10 piastres, or, in all, 12½ francs per square metre. Foundation walls, 10 to 11 francs, above ground, 14 to 16 francs; partition walls, 10 francs; dolma walls, *i. e.*, wooden framework filled with framing, 6 francs; vaulting, 8 francs—all per square metre.

Various Details.—Facade stone, 100 pieces, from 10 to 14 francs. External pointing, ½ franc per square metre. Corner stones or quoins, 2 francs each. Lintels and cornices; 3 francs per lineal metre, or 40 francs per door and window opening. Plastering, 1½ to 2 francs per square metre. Cementing new cisterns, 3½ to 4 francs. Plastering ceiling, 2½ francs. Tile roofs, including wood, labor, nails, etc., 12 francs; with heavier woodwork, 15 francs. Carpentry for window, glazed, painted and fixed, 50 francs. Per internal door complete, 50 francs; per pair of shutters complete, 40 francs. Iron bars fixed, ½ franc per kilo. Girls' school, Jerusalem, including boundary wall, gate-house and cistern, and clearing site, about 12 francs per cubic metre. Not plastered.

In the discussion that followed the lecture, Mr. A. C. Dickie said: The more modern Jerusalem had really few attractive features as regarded the construction of buildings. New settlements were springing up outside the walls of the old city, and German shops were being opened. One of these settlements or villages had become famous, inasmuch as old and empty petroleum tins had been largely employed in its construction. The Kaiser's visit to the Holy Land would long be remembered by those interested in the antiquities and beauties of Palentine. Prior to the Kaiser's visit to Jerusalem, when the authorities were trying to improve the look of streets, etc., several acts of vandalism were committed. Although the streets were then said to present a cleanly appearance, it was hardly true, as the refuse and dirt of the principal streets were merely swept into the smaller and less frequented ones. Where old gilt-work in mosques had become dull, a little yellow pain was used to restore (such was the taste of the Turk) its first charm.—*Stone.*

VALUABLE INFORMATION CULLED FROM OUR EXCHANGES.

THE first contract in the construction of the largest grain elevator in the world was let a few days ago by the great Northern railway. Schmidt Brothers of West Superior got the contract for the foundation, their bid being $85,000. The elevator is to be located at West Superior, and will be built of steel, at a total cost of over $2,000,000. Its capacity is to be 6,500,000 bushels of grain, or 2,5000,000 more than the largest existing elevator.

THE Treasury Department last week sent invitations, under the provision of the Tarnsey act, to twenty leading architects to submit competitive plans for the new custom house building, to be erected on the Bowling Green site in New York City.

JAMES G. Hill, of Washington, D. C., has been selected selected to design the new building for the government printing office, for which Congress appropriated $2,000,000.

ARCHITECTS and engineers are watching with much interest the character of foundations now being put in for the new office building which is being erected at 57 Washington street for the Western Methodist Concern, after plans by Architect H. B. Wheelock. The entire structure with rest on 32 caissons or concrete wells, each 4 feet in diameter, with a bearing of 9 feet at the bottom on hardpan, which is about 75 feet below the street grade. The maximum load on each well is 617,500 pounds, including the weight of the concrete, or about 9,700 pounds per square foot. This will not create any perceptible impression on the hardpan found in this location. The manner in which the concrete is lowered and tamped in these wells will also cause a friction against the walls of clay for its entire height. There is practically no settlement in this form of foundation, only that due to the shrinkage of the concrete, thus avoiding the uncertain settlement experienced in most all of our skyscrapers having the steel floating foundation; the particular preference over the pile foundations is the fact that surrounding property and buildings are not disturbed in any way, add that every concrete column acually rests on hardpan.—*The Construction News.*

THE Report of the Pennsylvania State Capitol Commission has been made public, and the politicians are busy extracting from it nutriment for their respective views of public affairs. With these, of course, we have nothing to do, but it is interesting to observe that the Commission seems simply to have thrown the instructions of the Legislature overboard, at the suggestion of the architect. That the latter should have thought it desirable, instead of scattering the departments among a cluster of separate buildings, to gather them under a single roof, is quite intelligible; in fact, the same idea would occur to most architects; bnt that the Commission should have thought itself authorized by the statute under which it acted to adopt such a scheme is extraordinary, and it seems to us more extraordinary still that their action should have been supported by the Courts. If a man should commission another to buy him a coat, for $50 mentioning that he expected at some latter time to get the rest of a suit, and his agent should bring him back a shirt, with the information that he had expended the fifty dollars for this, and had ordered in his name a four-hundred-and-fifty-dollar suit, he would hardly think that he had been well served; yet this is practically what the Commission has done for the State of Pennsylvania; for, according to its report, it will cost four million dollars, in addition to the amount already expended, to complete the building according to the designs prepared by the architect with the Commission's approval. If this is what Pennsylvania people like, and what Pennsylvania courts consider proper, we have nothing to say, except to warn architects and other unsuspecting people from trusting either in future. Meanwhile, we commend the closing paragraph of the Commission's report, with which it presents the shirt to the would-be purchaser of a coat, to the attention of the curious. "That the building in which the General Assembly now sits is not as handsomely decorated and finished, either internally or externally, as many people of the State would desire, arises solely from the fact that the Commission did not have at its disposal any money to expend upon unnecessary ornamentation." We hope that the owner of the shirt will be quite satisfied with this explanation.—*The American Architect.*

THE London Chamber of Commerce recently appointed a committee to inquire into the subject of secret discounts and commissions, by which many persons endeavor to secure business, at the expense, of course, of honest people. The report of the committee showed the extent of the evil, but without proposing any definite means for correcting it: and the architects, who see more than other professional men, perhaps, the injustice done to innocent persons by frauds of this sort, seem to have been roused to an earnest desire to have them corrected, if possible, by some sort of concerted action; and as the same evil flourishes here, our architects will watch with interest the course of their English brethren. In England, as here, the trouble does not seem to lie so much with the giving of bribes, which have small attraction for architects, whatever they may have for official persons, as with the practice of certain dealers and manufacturers of having a variety of prices for the same thing, varying in inverse proportion to the honesty or inexperience of the purchaser. We heard of a case recently, for example, where a certain appliance for steam-heating was called for by name in the specification for a building. The article was a good one, and the architect undoubtedly thought he was doing his employer a service in demanding it in the specification. About the same time, another contract of nearly the same importance was carried out for steam-work, in which the contractor, although not restricted except by a general provision that he should do a good job, used the same appliance. In everything but price the articles used under the two specifications were exactly similar, but the contractor who was required by his contract to use that particular thing,

and no other, had to pay more than three times as much for it as the contractor who was left at liberty in the matter; and, of course, the extra cost came out of the pocket of the owner of the building. As any architect knows, this is a very common experience, and notwithstanding the impassioned appeals of manufacturers to specify their goods, and their gratuitous supply of specifications mentioning them, the older men in the profession are very reluctant, and with good reason, to call for any appliance or material whatever by name in their specifications. In many cases, knowing the superior quality of a certain article, they would be glad to do so, if it were not for their conviction that they would in that way expose their clients to the risk of being robbed; and they prefer to leave the matter open to competition, even if they have to accept something not quite so good as they would like. That this state of things is not satisfactory either to architects, who wish their cliants to have the best things made, or to the manufacturers, who think that their efforts to improve their goods ought to be encouraged, is evident; but the latter have only themselves, or more probably, their selling agents, to thank for rhe view which architects take of the matter. No doubt injustice is done to some honoroble manufacturers by the suspicion and discredit which the tricks of the other sort have aroused in the profession; but this is not the fault of the architects, who have no means of judging, except by analogy, of the conduct of parties not personally known to them, and are columns are always open to the affidavits of dealers who can lay their hands on their hearts and swear that the net price of their goods to contractors is exactly the same where they are called for in the contract as where they are struggling to "introduce" them in competition with other articles of the same sort.—*American Architect.*

THE twenty architects invited to enter the competition for the New York custom house have all signified their acceptance, and the Treasury Department has mailed them the programme upon which the competition will be based. The new custom house will be one of the most important structures ever erected by the government outside of Washington, its cost being variously estimated between three and four million dollars. The architect who will compete for the plans for the new building are: In Chicago—D. H. Burnham & Co., Henry Ives Cobb; in New York, McKim, Mead & White, George B. Post, Bruce Price, Carrere & Hastings, Francis H. Kimball, James B. Baker, Cady, Berg & See, Clinton & Russell, Robert W. Gibson, Israels & Harden, Babb, Cook & Willard, H. J. Hardenbergh, Cass Gilbert, Trowbridge & Livingston, George Martin Huss, Howard, Cauldwell & Morgan; in Boston, Peabody & Stearns, Shepley, Rutan & Coolidge. The programme for the building, as sketched out roughly to the proposed competitors, suggests a structure six stories hight, with 212,000 feet of floor space the absolute requirement. A hint is thrown out that it may be desirad to add two more stories later, and designs may be drawn with reference to this possibility. The material of which the building is to be constructed is not designated, but is left to the discretion of the designers. According to press dispatches, it is the intention of the Secretary of the Treasury to award to the successful competitior the full five per cent commission on the total cost of the building. A commission, composed of the supervising architect of the Treasury and two architects or experts in the construction of buildings, are to be th judges, and report to the Secretary of the Treasury as to the relative merits of the designs and plans submitted.—*The Construction News.*

MILL-CONSTRUCTION is being severely criticised in Chicago, and, if the underwriters have their way, it will soon be a thing of the past. The loss-record for this class of buildings—even sometimes when equipped with automatic sprinklers—has been unsatisfactory, and before the committee of the Board of Underwriters the argument was made that such structures are destroyed even more quickly than buildings of ordinary construction. Rapidly-spreading fires and total losses, it was stated, seem to be characteristic of the class. The Kaestner, Armour, Felt, Traders' warehouse, Jackson Street, and other buildings recently wholly destroyed, are cited to prove their lack of fire-resisting qualities. It is therefore, proposed to suspend all allowances for unequipped mill-constructed buildings, and a sub.committee has been authorized to make the necessary investigations, and report as soon as possible. The underwriters' association has for years made liberal allowances for mill-construction, upon the theory that such buildings were slow-burning, and fires in them could be extinguished with moderate loss. Possibly for this reason, and because so many rates would be upset by withdrawing all existing allowances, it is xuite likely that whatever action is taken will apply only to new structures. But the day of mill-construction has probably passed, not to return.—*Exchange.*

A COMMITTEE appointed by the American Institute of Architects reported upon the subject of architectural education at the last annual convention. The first architectural school in the United States was established in 1869, at the Massachusetts Institute of Technology, by Prof. W. R. Ware, who is now Professor of Architecture in Columbia University. Since that time flourishing schools have been established at Cornell, the University of Illinois, Columbia University, Syracuse University, University of Pennsylvania, University of Chicago, Harvard, Tulane, and McGill Universities. Since their establishment no less than 3250 students have received instruction; 650 have hraduated, and a large number are now in practice. The committee favored the establishment of an educational requirement for admission to the Institute, and suggested that the diploma of a graduate of a recognized school might be accepted in lieu of an examination.

A MONUMENT to General Lafayette is now in course of construction on the Brandywine battlefield, in Chester County, Pennsylvania, near the spot where the general was wounded. The height of the structure is to be 78 feet, and the size of the base 24 feet square. The material is Brandywine granite, and the largest stone, which is the die, is to weigh fifteen tons. On this stone are to be four bronze panels, inscribed with the full record of General Lafayette, setting forth the battles he was engaged in and designating on what spot he was wounded. The monument is to be crowned with an historic broze figure of Lafayette 12 feet in height. The memorial is the gift of John G. Taylor, of West Chester, who nat only builds the monument but has set asid a sum for the perpetual care of the surrounding grounds.—*Exchange.*

FIRE PROTECTION OF TALL BUILDINGS.

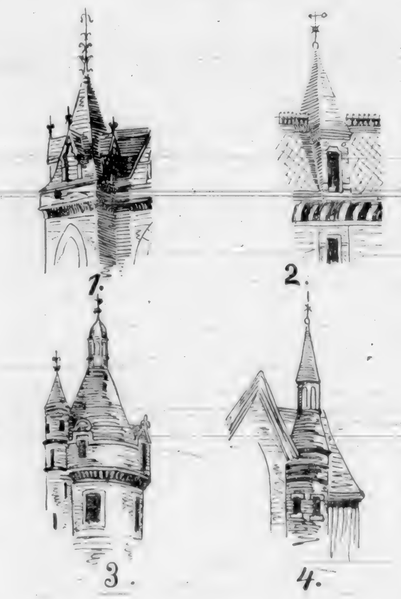
IT WILL be remembered that when the upper eight stories of the Home Life building were out in the recent fire, the chief of the New York Fire Department stated that the failure of the firemen to do any effective work above the ninth story was what he had predicted whenever one of these tall buildings came to be tested by a serious fire. There is a limit of height above which the ordinary methods of fire-fighting by pumping water through a hose are inadequate. Much valuable time is lost in dragging the hose from floor to floor; it is always liable to injury from fire or falling debris; and of course there is the danger of bursting from overpressure, a risk that naturally increases when the water has to be forced to the upper floors of a twenty-story building.

The New York Fire Department has recently made a test of the height at which an effective stream of water can be delivered from its engines, which shows that our tall buildings are better protected than is generally supposed. A fire engine was connected to the mains and to a standpipe that extends the full height of the St. Paul building, and succeeded in forcing a considerable stream of water from the roof—at a height of 307 feet above the street level. With a pressure of 180 pounds at the engine, the water was thrown over St. Paul's Church, on the opposite side of Broadway, and fell into the churchyard beyond, a horizontal distance of about 250 feet. Unfortunately, the failure of one of the couplings on the standpipe within the building prevented the test being made with the maximum pressure at the engine of 300 pounds to the square inch; but enough was done to prove that the engines of the department can deliver water at a satisfactory pressure on any of the floors of our tall buildings. At the time the standpipe failed the engine was throwing over 250 gallons a minute at a height of over 300 feet, with only 60 per cent of the maximum pressure.

While it is true that the tall buildings are provided with their own fire service in the shape of tanks on the roof or special fire pumps in the basement, experience has shown that the system is not very reliable. The tanks are liable to be empty, or the pumps may not be available because of insufficient steam supply in the boilers, or the whole plant may be crippled by the flooding of the basement during the progress of a fire. But by the new system, if a fire should break out in a building supplied with adequate standpipes and a good elevator service, the firemen will be enabled to command a good service of water on any of the highest floors within a few minutes after reaching the scene of the fire.

The failure of the standpipe in the St. Paul building suggests that the fire system of these tall structures should be put in under the rigid inspection of the Building Department; that it should be of ample capacity; and that it should not be passed by the department until it has been subjected to a test pressure considerably beyond that which will obtain in actual service.

A further development of the idea of having the service of these buildings operated by the engines of the Fire Department would be to lay down separate salt water mains at stated intervals from Broadway to the Hudson and East Rivers, with connections at the water front to enable the powerful pumps of the fireboats to be concentrated upon a fire. This system is already installed in some Western cities, and it provides a supply of water far in excess of anything that could be secured by the use of the ordinary fire engines. A combination of both systems and the provision of ample standpipes in every tall building would render these structures practically proof against destruction, so great would be the flood of water that could be let loose upon a fire. It should also be borne in mind that these towering buildings would not only be indestructible themselves, but they would afford an excellent protection against the spread of a conflagration. Their great mass would form an efficient fire-screen, tending to localize an outbreak, while they would serve as giant watertowers, from the upper floors of which a vast amount of water could be thrown upon the burning buildings below.—*Scientific American.*



PORTLAND CEMENT MADE FROM SLAG.

PORTLAND cement from iron slag has been so profitably and successfully produced from the refuse at the Sparrow's Point Works in Maryland, and at the works of the Illinois Steel Company, that a plant is to be established at Birminghrm, Ala. The supply of slag will be drawn from the Emsley furnaces of the Tennessee Coal and Iron Company, the plan being to have an initial capacity of 1000 barrels a day. Machinery has been ordered for the plant, which will be in working order, it is expected, in about four months. This utilization of what was heretofore a useless by product of pig-iron works is one that promises to add largely to the profits of the ironmakers, even though the production of the cement, as in this Birmingham case, is turned over to an independent company.—*Boston Transcript.*

BOOKS AND PERIODICALS.

BRIDGES AND FRAMED STRUCMURES, an illustrated monthly magazine, has made its debut with the April number. It is published by The Ranck Publishing Co., Chicago, at $3 a year. The initial number contains the following interesting and readable contributions: A review of the life and works of Sir John Fowler; Pneumatic caissons for ordinary foundations; Assumptions made to determine draw span stresses; The architecture of bridges; Modern Spanish bridge engineering; The bridge work's estimating department; Chemical and physical construction of steel. Measurements for granite viaduct.

The matter is well edited and digested as well as pertinent to the field of enterprise which the title indicates. The articles are aptly illustrated, and the magazine printed on good paper. We bespeak for it a wide field of usefulness.

TRADE NOTES.

THE Grand Rapids Carved Moulding Company are known all over the country as the only concern that manufacture the real thing in carved mouldings. There are imitators and pressed mouldings and pressed pot metal that is in use in ornament, but when you want the genuine article in carved mouldings the above firm are the people who can supply your wants. Why? Because they are cut, the wood is displaced. They bear the same relation to the hand carved work that the machine stuck or shaped mouldings of the present have to the old hand worked. They are more even and perfect than can possibly be produced by hand and at a very small per cent of the cost. Where can you find ornaments that are acknowledged as correct as the Fgg and Darts, Dentals, Fliets, Beads and numerous others that they produce? Send for their catalogue. See advertisement on page iii.

THE TALLEST CHIMNEY IN AMERICA.

THE trade press throughout the country has been giving considerable time and attention to the tall chimney and the electric power station of the Metropolitan Street Railway Company, in New York. New York City will soon be the possessor of two of the largest electric power stations in the world, says *Clay Worker*, designed to furnish current to two street railways. The delay in introducing electric traction has been a very advantageous one, since it is now possible to utilize the latest advancements in electrical engineering in both the generation and transmission of high potential currents. A further advantage is the concentration of all the current-generating machinery in a single enormous station, so located that coal can be obtained and ashes deposited at the lowest possible cost, and where an ample supply of condensing water is available.

Alternating current at high potential will be transmitted from this central station to small sub-stations scattered throughout the system, where it will be transformed to direct current at low voltage, and fed directly into the mains along the road. The new power-house has been designed for a normal output of 45,000 horse-power.

It will be divided into two parts, one containing the boilers and coal bins and the other the engines and generators. There will be 87 water-tube boilers arranged in three tiers, each having a maximum capacity of 800 horse-power. The storage bin will be capable of holding about 10,000 tons. The engine room will contain 11 engines, each direct-connected to a three-phase 6000 volt generator. The engines have a maximum capacity of 6000 horse-power each, but an economical load of about 4000 horse-power.

The most conspicious feature of this new plant is the immense brick chimney, the largest ever constructed. A solid block of concrete 88x85 1-3 20 feet forms the foundation. Starting with a square pyramid base 55 feet on a side, it gradually diminishes until at a height of 15 feet from the ground it is but 40 feet, at which point it continues up to 80 feet, with a side dimension of 38 feet, 10 inches. At this height it begins to change to a circular section, which change is completed at 95 feet, from whence it continues with a taper of five sixteenths inch to the top. The ornamental top begins at a height of 317 feet, the chimney at that point having a diameter of 26 feet, 10 inches.

A 12-inch fire-brick wall extending up 85 feet divides the chimney into two semi-circular compartments, preventing the current of hot gases from one set of boilers having any influence upon the gases coming from the flues on the other side. About four feet below the floor of the lowest flue, the fire-brick lining of the chimney commences, and extends about 8 inches in thickness to 5 feet above the upper flue, and from that point, 4 inches in thickness up to 115 feet.

The weight of the overhanging enlarged portion at the top is counteracted by three steel rings, the first at a height of 333½ feet and the other two at 3 and 6 feet respectively above the first. In the thickest portion of the cap the brick work is 6½ feet thick, sloping off to 20 inches at the top The chimney is protected at the top by an iron cap made up of 40 cast-iron sectors bolted together into a complete ring and anchored to a steel ring embedded in the brick work about 14 feet below the cap. The diameter of the cap at its widest portions is 35 feet and the inside or flue diameter is 22 feet, or the same as the interior of the chimney all the way up.

The chimney is well protected from lightning by ten copper rods, 1¼ inches in diameter, projecting 6 feet above the top, terminating in four pronged points, each tipped with platinum for about 2 inches.

The fact that mechanical draft will be used at the other station, will furnish available data for drawing interesting comparisons. This station will have four stacks of modern height, sufficient only to discharge above the nuisance level. Taking the cost of the immense chimney at about $100,000 and the cost of the induced draft plant at about one-th rd of this, and considering interest, depreciation and all standing expenses, it will be very interesting to calculate the relative merits of the two systems of producing furnace draft.—*Clay Record.*

DUNHAM, CARRIGAN & HAYDEN CO.
17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our AMERICAN SLIDING DOOR HANGER for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

☞ See a full size working model at our store.

FACTS ABOUT PAINTS.

PHŒNIX

PURE

PAINT

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

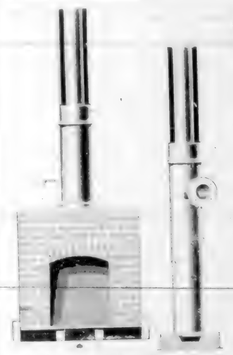
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET, SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one. as a live man is of a dead man.

CLAWSON'S PATENT THIMBLE.

Price. $2.50 for any size from 18 to 26 inches.

Send for illustrated circular.

$5,000 Worth of Plans, Drawings and Details for Only $4.00.

Pallisers New Cottage Homes

With Detail Drawings.

The best, the largest and the most practical and complete work ever issued on plans of medium and low cost houses, containing one hundred and sixty new and original designs for cottages and villas, including every description of modern dwellings for the seaside, the south, winter and summer resorts, etc., double houses, country houses, city, suburban, town and city residences and apartment houses, of every kind and variety, in every conceivable combination of stone, brick, timber, plaster and frame costing from $75 to $7500, giving all the comforts and conveniences, and suited to every taste, location, want, etc., also 50 new designs for city brick block houses. The whole affecting the largest field of selection from the most approved and latest style of architecture. Illustrated by plans, elevations and perspective views from practical working drawings to a uniform scale, and not like the impractical sketch views which fill so many cheap architectural books that are in reality issued only as catalogues and price lists of printed plans. 1500 detail drawings covering the whole range of interior finishing and interior construction and ornamentation of the plans in this work and all to a uniform large scale. Cabinet work of every description, mantels sideboards, bookcases, cabinets, dresses, etc., in almost endless numbers and variety. Stairs, hand railings, newels and balusters. Details will be found to cover every question that can arise in constructing dwellings of every kind. Fences, summer houses, pavilions, conservatories, arbors, well curbs, outbuildings, etc. Twelve new designs for stables and carriage houses, descriptive letter press, giving practical suggestions, cost, etc., which would alone fill an ordinary book of 150 pages. Details of furniture of every description, so plain that any good mechanic can understand and execute the same. Perspective views of four houses printed in colors, showing how to paint. Specifications and form of building contract, etc. The value of this work to builder cannot be estimated, as it contains plans and details for just such houses as they are called on to build every day. There is not a contractor or builder in the country that can afford to neglect this book. Building mechanics should all posses it. No matter what kind of a job they are called on to do, here are the ideas to help them out. Ideas are as necessary as tools and this work contains thousands of practical ideas. It is the educated mechanic that goes to the front every time. Prepared by PALLISER, PALLISER & CO., the well known architects in one large volume 11x14 inches, printed on heavy cream paper, handsomely bound in boards and leather and sent to any address, on receipt of $4.00 by the

LACONIC PUBLISHING CO.,
123 Liberty St., N. Y.

Palliser's Useful Details

AN IMMENSE WORK

New Edition just publishedin paper portfolio, 14x22 inches, good paper and good prints. An entirely original and practical work that should be in the possession of every carpenter, builder, woodworker, stair builder, sash, blind and door maker, cabinet maker, mason and plasterer and all building mechadies. *The American Architect and Building News* says of this book: "We have often wondered that some American publishers did not undertake to produce such a book, for it has been evident that a large sale could be found for a work showing American constructive details of a good character, but at length has appeared just the work, and which has about it the indications of a useful and successful undertaking.

Useful to those who buy it and successful as a business adventure for the authors and publishers. Grouped upon single folio sheets are a multitude of details well arranged and properly co-ordinated, of such constructive features as must be wrought into the small houses, stables, shops, etc., in which construction nine-tenths of the mechanics an a large proportion of the architects of this country find occupation. Useful details as they are properly called. When one sees the prodigality with which the authors have made public their ideas, one cannot but smile afresh at the remark of a foreign architect "When I got an idea I wouldn't be giving it to the other fellows, I'd be keeping it for my own work."

Carpentry and Building remarks about "Useful Details": "The plates are large and withall are crowded, as though space were valuable. This is in one sense an advantage, since many more designs are obtained for the money expended.

We will send this great work, prepared by PALLISER, PALLISER & CO., the best known architects in the world, to any address, prepaid on receipt of only $2.00. Address all orders to

LACONIC PUBLISHING CO.,
123 Liberty St., N. Y.

Every Man a Complete Builder.

A $5.00 BOOK FOR ONLY $1.00

How to Build a House

Be your own architect

This book will save you hundreds of dollars. If you are thinking of building a house you ought to buy the new book, PALLISER'S AMERICAN ARCHITECTURE; or, Every Man a Complete Builder, prepared by Palliser, Palliser & Co., the well-known architects.

There is not a builder, or anyone intending to build or otherwise interested, that can afford to be without it. It is a practical work, and the best, cheapest and most popular book ever issued on building. Nearly four hundred drawings. A $10 book in size and style, but we have determined to make it meet the popular demand to suit the times.

It contains 104 pages 11x14 inches in size, and consists of large 9x12 plate pages, giving plans, elevations, perspective views, descriptions, owners' names, actual cost of construction, NO GUESS WORK, and instructions. HOW TO BUILD, 70 cottages, villas, double houses brick block houses, suitable for city suburbs, town and country, and costing from $800 to $6500; also barns, stables, school houses, town halls churches and other public buildings, selection of site, employment of architects. It is worth $5 to anyone, but we will send it in paper cover by mail, postpaid, on receipt of $1.00; bound in cloth, $2.00. Address all orders to

The Yale & Towne Mfg. Co.

LOCAL OFFICE:

Mills Building, San Francisco.

The "Yale" Locks with new Paracentric Key, afford the highest standard of security. They are made in hundreds of styles and sizes, adapted to almost every possible use.

The Builders' Hardware, made by this Company, and used in connection with the "Yale," "Vulcan" and "Branford" lines of locks, forms collectively the largest assortment in the trade and covers respectively, as used with these locks, fine, medium and cheap goods.

The Art Metal Work (or Hardware of Ornament) as illustrated and listed in the No. 16 Catalogue, includes the largest collection of Ornamentations and patterns of this class in the world; not only those usually required but also a vast variety of special pieces. In all Yale Art Metal Work an intelligent interpretation of design may always be found.

As to Prices. While the goods made by this Company are always "the best for the money," the range of products and grades is such as to meet conditions where cost is a FIRST requisite, as well as where the greatest perfection of design and finish is alone considered.

OLD FASHIONED QUALITIES.

Honesty and integrity never go out of fashion.

They were in force 68 years ago when we began to make Roofing Tin.

They are still in force to-day, but they are not so common.

We have continued to make Tin in the only way in which the best Roofing Tin can be made. The "TAYLOR OLD STYLE" brand is made exactly the same as in 1830.

That is why it is the best Tin to-day as it was then.

LEARN TO STUFF BIRDS! LEARN TAXIDERMY! LEARN TO-DAY!

Because success is guaranteed from the start! Because the work is pleasant as well as profitable. A collection of birds is both beautiful and valuable. Birds, animals, fish, reptiles, etc., may be preserved with little trouble, as records of the day's chase.

Boys, girls, men and women can do nice work from the start, and can become expert in one week. Mounted birds find a ready sale; besides you can make money tenching your friends. Every school should have a collection of native birds and animals.

TAXIDER is a compound of wonderful embalming power. It is not necessary to skin birds or animals when using Taxider. Birds when mounted with Taxider become as hard as stone, and will last a thousand years undisturbed by moth or time. No tools required except those that every one has. One box Taxider is enough to mount 30 birds the size of a quail, with full instructions for mounting everything. Also instructions for tanning skins for rugs, etc. Price $1.

SEE WHAT ONE MAN SAYS

TACOMA, Wash., Aug. 9, 1898.—Mr. F. L. Ackley: I received the box of Taxider some time ago. It works fine. I have just finished mounting a beautiful swan. I have already a nice collection of birds, and a class of seven boys. It is really wonderful how it works. The very first bird I mounted was a success. Please find enclosed money order for one dozen boxes. Please rush, as I am in quite a hurry. Thanking you for past favors,

I remain truly yours, J. H. FLANDERS, Tacoma Wash.

I have letters like this from hundreds of people, and all are having success. Send for a box to-day. You can learn in one hour. Remember, success is guaranteed from the start. Liberal discounts to agents. Taxider is manufactured by F. L. ACKLEY, Sioux City, Ia., U. S. A.

AS A FEATURE in building designs, color is receiving some attention. There is here a field for exploitation, the subject being one of greater interest than at the first glance appears. Asthetically it belongs to high art, and should be handled by artists in color, and by students of art such as Ruskin.

There is, moreover, the natural side to it, nature being the first teacher of art. Nature decrees that the sky and the sea should be blue or gray, in different shades; that the earth should be brown, in many shadings, from the yellow brown of the desert to the dark muck of the bog; and that the herbage and foliage that cover the earth should be in various tints of green. Gray is also a strong hue on nature's palette. With this she paints rocks and the stems of trees, and softens her too vivid greens everywhere they occur in large masses.

But nature does not confine herself to these general colors. She illumines the sky occasionally with rainbows and clouds edged with the strongest prismatic hues. She decorates the fields with flowers of many dyes, and plants in endless shades. She variegates her rocks, and richly colors her minerals. She beautifies with consummate skill inorganic, organic, and animal life by means of her wondrous pigments.

All this is for some purpose. The color scheme of the universe is intentional. It is not an accident nor a vagary of the infinite mind. That it largely contributes to the welfare and happiness of man there can be no question. That we have failed to appropriate to ourselves all the good there is in it, goes without contradiction. But how to make it apply to our house-building—that requires some thought.

If we were to undertake to follow the painter of the Universe, we should make all large masses of building of some quiet color, using brighter tints only for decoration, and that sparingly. But we moderns have not yet ventured upon the experiment to any considerable or appreciable ex-

tent. No doubt we shall make many blunders before we master the art of building houses singly, or in rows, made beautiful by color effects.

There is something, however, which can be done in the interest of dwellers in cities—and especially in the city of San Francisco—whose eyes are being ruined by having to see by sunshine reflected from light-colored walls. Bad as it is to strive to see by insufficient light, it is worse to have to endure the torture to the eyes which comes from the glare thrown into rooms frome neighboring house, painted, as a majority of San Francisco houses are, of a tint closely resembling the sands of Sahara. The desert itself could hardly be more fatal to vision than this reflected light inflicted upon helpless dwellers in buildings on the north or the west side of lots or streets built up on the opposite side with these colorless houses.

The effect of such light upon the optic nerve is entirely different from that of pure sunshine. Your room may be flooded with sunshine and no harm come to you, but light thrown against a wall and returned into your eyes, has the same effect that is produced by shimmering water or bright metal. Yet thousands of women sew, or write, or pursue other nerve trying occupations in just such light. Doubtless also, some schools are similarly situated, and the children are having their eyes ruined. Men's offices do not suffer so much from this cause, being in more closely built up districts, and among darker walled buildings.

Here is an opportunity for experiment in house coloring. From the expedient we may reach the beautiful, and cities be made studies of art instead of ugliness. Science must be invoked even in such matters as house painting.

ARCHITECTURE OF THE AMERICAN COLONIES.

THERE is no such thing in America, in the United States, at least, as a distinctive order, or a strictly American style of architecture. The aboriginal dwelling was usually a moveable one, owing to the wandering habits of the native races. Those tribes who lived by fishing, hunting and corn-growing, as along the Atlantic Coast, built more substantially, out of logs and bark of trees, than those on the western prairies who lived by the chase and root digging. These being almost constantly on the move, sheltered themselves in tepees or tents of a circular or conical form, with an opening at top for the passage upwards and outwards of the smoke of their fires. Constructed of dried skins of animals, they were impervious to wind, and protected their inmates from the cold of the severe winters of the plains, especially as they were usually placed in sheltered locations.

Still farther west, under the milder skies of the Pacific Coast, a brush tent, or wickiup, sufficed for the gathering place of the family, and could be abandoned at pleasure. This was the style of dwelling of the California coast tribes. But farther north, in and above the Columbia River region, rude houses were constructed of planking made out of the easily split cedar of the northern coast.

These houses consisted of a basement a couple of feet in depth, often of from thirty to fifty feet in length, and twenty o thirty feet in width, over which was built the wooden part of the structure. This was done by setting posts at the corners, and between, to which the planking was fastened by such means as were at hand. The wooden walls being set back two or three feet beyond the earth wall of the basement, left a bench of earth quite around the interior, which, being covered with grass matting, and skins, served for seating and sleeping accommodations. The roof, of planking and cedar bark, was supported by a ridge-pole and stringers. The only light admitted came through the doorway, which was at one end, and a square opening in the roof, left for the escape of smoke, the fire being built upon the earthern floor in the center of the house. It will be perceived that this dwelling, which cannot be classed under any recognized style, belonged nevertheless to what is known as the trabeated, or beamed style, like the Egyptian and Grecian structures. It is easy to trace the differences to their causes, while recognizing the single underlying idea of an oblong structure, with upright posts or columns in certain positions, and flat, or nearly flat, roofs.

Still farther north, indeed, we come upon detached columns outside the walls, rudely carved with genealogical emblems, or tokens, much after the Egyptian example of a goddess-faced capital. The human intellect, it would appear, starts out upon similar lines of progress throughout the world.

* * *

The first buildings by the white races in America were mere make-shifts—architectural accidents—due to unusual circumstances or exigences, like those found at Newport and Woods Holl, Rhode Island, believed to have been erected by Norsemen, about 1507. That one at Newport, known as the "Old Mill," is a round structure of stone, supported upon short pillars and arches, in the early Roman or Etruscan style. The other, at Woods Holl, is also round, and of stone, but is built up from the ground, and has a battlemented top. It is without openings in the wall, except the entrance, and narrow windows immediately under the cornice, suggesting the idea of a fortification.

* * *

The second oldest building by white people in what is now United States territory, and the oldest known residence, is in St. Augustine, Florida, which was settled in 1564, when the monks of St. Francis erected this house for their occupation. It is constructed of coquina, a mixture of sea shells and mortar, which forms a cement as solid as natural rock.

Sir. Francis Drake, while roving the seas in quest of riches, in 1585, destroyed the town of St. Augustine, but was unable to demolish this monastery. Its age, quaintness of design, and historic interest, has of recent years lead to repairs, and to its preservation as a museum, where has been gathered relics of past centuries. The round tower and the walls of the lower story are intact, the latter being sustained by heavy buttresses. The frame work of the second story gives evidence of being more recent by a century; and some even more modern features appear, in windows and balconies.

A deputy of the Spanish government in 1590 came into possession of the building, which remained in the family until 1882, when it was sold to Dr. C. P. Carver, who more recently transferred it to J. H. Henderson, Esq., the present owner.

A feature of the house is a curiously designed door-knocker of wrought iron, weighing twelve pounds, which was taken from the ducal palace of Ponce de Leon in Seville, Spain. Evidently, it was not intended that the inmates should yield too much to the sleepy influences of the Florida climate.

The furniture of the house is antique. Among the art treasures are an elaborately carved bedroom set of the time

The Oldest Hnuse in the United States at St. Augustine. Florida

of Louis XII, and a rosewood sideboard which was the property of Napoleon I. On the walls are paintings by the old masters once the property of the Spanish nobility. To these relics have been added a collection of ceramics representing all the rare colonial designs, including the Martha Washington plate, presented by La Fayette and other Frenchmen.

This building gives us the first and the last glimpse of a power which once possessed the continent. It is the irony of fate that just as every vestige of former empire is being wiped off the map of the new world discovered by Spain, we, her latest conquerers, should be carefully preserving relics of her earlier occupancy. We pay to a glorious past the reverence which even a recreant present cannot overcome.

* * *

There is still standing in Jamestown, on the Potomac, the bell-tower of a church erected by the first colonists of Virginia in 1610—three years only after the settlement of that place. The building was sixty feet in length by twenty-four feet in breadth, and constructed of brick. It had "a baptismal font, a tall pulpit, a chancel of red cedar, and in the tower two bells." The tower, which is still as firm as stone, stood over the vestibule, which had an arched entrance.

This first Protestant church in America was the type after which colonial churches were built for many generations, and after which they are still built in new settlements generally—the steeple, with a single bell, being substituted for the more costly and dignified tower. The portico was often omitted, puritanic plainess dispensing with whatever was unnecessary, or paucity of means rendering architectural effects impracticable. But churchbuilding for at least two centuries adhered to that early Christian type, which, as we have seen, was born in Rome, and was descended primarily from the Egyptian plan of temple-building. The Gothic graft which modified it fourteen hundred years later still continues to derive its sap from the ancient root.

Williamsburg, the old capital of Virginia, was the seat of the second church in this colony, and was founded in 1632. As befitted a church of England edifice, where royal governors and other titled personages joined in the liturgy, and listened to mild discourses upon the divine right of kings, was a more costly building than its predecessor, as well as a larger one.

Families of ordinary mortals sat in large square pews, much at their ease, but the king's representatives and their families sat in the "royal gallery," a room of considerable size, which they entered and departed from by a private door, as did royalty itself in Old England. An American lady, a republican, is to-day supporting similar vice-regal customs in the Queen's possessions in the East Indies. "So runs the world away."

There are no detached columns in the Williamsburg church, which is still in a good state of preservation, but simulated square pillars support the cornice beneath the ceiling, which is decorated. There are tall arched windows, and a square altar-rail guards the sacred and spacious enclosure where stands the reading desk, and the actual gray marble baptismal font from which the Indian princess Pochahontas was baptised into civilization, and marriage with John Rolfe. The silver communion service was a gift of Queen Anne.

* * *

William and Mary College, built in 1693, and burned, was rebuilt in 1705, and may be taken as an example of college architecture in the latter part of the seventeenth century. Sir Christopher Wren had furnished the plan of the original building, which is now lost. That which succeeded it is a severely plain two-story structure, with a long frontage, and having many right-angled windows at equal distances apart. The roof is low, rather than high, and hipped at the ends. It has a portico, carried up to the roof, supported by arches, and supporting a pediment above the cornice. A small cupola or bell-tower rises from the center of the roof. Many similar college buildings have arisen all over the United States—all equally repellant to the artistic sense.

The house of the president of the college was built of brick made in England, of two colors, red and gray, used to present a checkered effect, a fashion which prevailed in the mother country two centuries ago.

* * *

A hundred years had brought to the colonies many of the architectural ideas prevailing or developing in England. These were not of the better sort, for art was again in a decline. Such as they were, they were modified and adapted to the climatic and other conditions in the new world.

The style of house most in favor with the Virginians was square, or nearly so, with a wide hall in the center extending through it, and large rooms opening on either side. A feature rarely omitted was the wide portico, with columns usually extending to the roof, and supporting a pediment. If the roof was low, it was hipped; if high, it had also dormer windows. Wings and supplementary buildings were addsd as required, but this was the central plan of the colonial "mansion house." The spacious hall had a grand staircase, sometimes spiral, sometimes with square landings to break the steep ascent, and with niches in the wall for statuary, or a place for the high-cased eight-day clock. The balustrade was high, and the posts supporting the rail often quaintly twisted or carved. If the house were large, the long hall might be divided by arches. In the immense rooms were fireplaces with decorated mantels of the hardest

wood or the finest marble. The furnishings were imported from Europe, and indicated the taste or the wealth of the owner.

* * *

The Dutch, who settled New York in 1614, brought with them from Holland certain architectural tastes and predelictions, which were shown in the thick walls of their low houses, their steepley-pitched and windowed roofs, and the indispensable "stoop," wherever it could be attached. Like the Virginians' portico, the stoop was the hospitable reception-room of the house.

In that rare and delightful book, "An American Lady," by Mrs. Grant of Scotland, is the following concerning the Dutch manner of living at Albany in ante-revolutionary times:

"The city of Albany stretched along the banks of the Hudson. One very long wide street lay parallel to the river, the intermediate space between it and the shore being occupied by gardens. A small, but steep hill rose above the centre of the town, on which stood a fort, intended (but very ill adapted) for the defence of the place, and of the neighboring country. From the foot of the hill another street was built, sloping pretty rapidly down until it joined the one before mentioned that ran along the river. This street was still wider than the other: it was only paved on each side, the middle being occupied by public edifices. These consisted of a market place, a guard-house, a town hall, and the English and Dutch churches. The English church, belonging to the Episcopal persuasion, and in the diocese of the Bishop of London, stood at the foot of the hill, at the upper end of the street. The Dutch church was situated at the bottom of the descent, where the street terminated. Two irrgeular streets, not so broad, but equally long, ran parallel to those, and a few even ones opened between them.

The town, in proportion to its population, occupied a great space of ground. This city, in short, was a kind of semi-rural establishment: Every house had its garden, well, and little green behind; before every door a tree was planted, rendered interesting by being co-eval with some beloved membered of the family. Many of their trees were of prodigious size and extraordinary beauty, but without regularity, every one planting the kind that best pleased him, or which he thought would afford the most agreeable shade to the open portico at his door, which was surrounded by seats, and ascended by a few steps. It was in these that each domestic group was seated in summer evenings to enjoy the balmy twilight, or the serenely clear moonlight.

"Each family had a cow, fed in a common pasture at the end of the town. In the evening the herd returned all together, of their own accord, with their tinkling bells hung at their necks, along the wide and grassy street, to their wonted sheltering trees, to be milked at their masters' doors. * * A town which contained not one very rich or very poor, very knowing or very ignorant, very rude or very polished, individual. * * These primitive beings were dispersed *in porches*, grouped according to similarity of years and inclinations."

Of New York Mrs. Grant says: "Society was there more various and more polished than in any other part of the continent. * * Unless a man, by singular powers or talent, fought his way from the inferior rank, here was hardly an instance of a person getting a subaltern's commission whose birth was not at least genteel, and who had not interest and alliance."

These allusions to New York colonial customs help us greatly to understand architectural features. The long, low, hip-roofed house of Albany, or of the manors along the Hudson, became in the capital city the aristocratic three-storied house of brick or stone, but without losing its distinctive Dutch style. New Jersey, also settled by the Dutch, still affords many examples of colonial buildings—of houses constructed of brown stone, the blocks thick enough to furnish window-seats eighteen or twenty inches deep.

These houses have, usually, the main building of one-story and an attic, in whose steep roof dormer windows are inserted; and a wing at one end, without the attic, which was devoted to domestic uses. Stout oaken doors, called "Indian doors," that opened across the middle, immense fireplaces and high mantels, with cupboards in every available space, were interior features of these houses, that often contained imported furniture and pictures of great value.

* * *

Perhaps the best example of the New York manor house is that of the Philipse family, at Yonkers, erected in 1682, which is in a good state of preservation. The plan is simply that of an oblong building of considerable size, and two-stories high. The roof is a mansard with dormer windows, and a balustrade running around the flat space at the top. The main entrance is by a door in the front end, which opens into a central hall. A small square portico, the roof of which slants forward from the wall, and is supported at the corners by two columns, shelters the doorway.

The windows, of which there are two on each side of the entrance, and five in the story above, are oblong, with twenty-four small panes of glass in each. Windows are placed at equal distances on the sides, six in the lower, and eight in the upper story. Two doors open on the side which faces a street, one having the porch with seats, the other being a walled porch, or "winter door," and leading to the kitchen. A delicate cornice is carried along the side of the building over the lower windows and doors, and a heavier one, of the same design, beneath the roof.

Certainly, a very plain, unostentatious house. But on the interior was lavished a wealth of decoration, architectural and applied. Painted ceilings, columns supporting tall carved mantels and mouldings, doorways crowned with sculptured pediments, handsome staircases, with quaintly-fashioned balusters, rich imported furniture and selections from European art-galleries revived in colonial homes recollections of a more settled, but scarcely more enjoyable existence over seas.

* * *

The Jumel mansion, or Fort Washington, in New Jersey, is an equally good example of the suburban New York mansion. It is in a style very similar to that of the Virginia town, or suburban house, being of brick, nearly square, with the imposing Roman portico whose pediment rises above the cornice of the upper story, supported by columns in the graceful Ionic order. The roof is hipped and balustraded, with the further relief from plainness afforded by a central chimney and a single painted dormer window. In the rear is a second detached building in a similar style, where the servants were quartered.

The interior of this house, built in 1758, at Harlem Heights, was finished and furnished as not many American houses were in that day. It had been erected by Roger Morris for his bride, Mary Philipse. In 1810 it passed into the hands of Stephen Jumel, a merchant of New York, who had married the beautiful Miss Eliza Bowen of Providence, Rhode Island. His wedding gift to her was this now celebrated mansion, which was refurnished with all the splendors of the wealth and taste of the period.

In addition to the contents of drawing room, dining-room, hall, tea-room, and many private apartments, was a gallery of paintings selected from art centers in Italy, France, Holland and Germany. Twenty-five thousand dollars was paid to the widow of a French count for furniture and jewels which had belonged to Napoleon I and Josephine, including articles which had previously belonged to Charles X.

After the death of Mousieur Jumel, his widow married Aaron Burr, whom she outlived, dying at the age of eighty-nine, in 1866. From first to last the house on Harlem Heights, back of Jersey City, sheltered at different periods the most distinguished personages of colonial times, military and civil, royalist and republican.

* * *

Turning to the New England colonies, we find a prevailing style not altogether dissimilar to the Dutch, yet with characteristics of its own equally well marked. Lands were

not possessed in large holdings by individuals, as in Virginia and New York; hence we have not the manor-house with its aristocratic dimensions and accessories, but the farm and the town house. The former was, for the first century, a very plain, and often a very uncomfortable residence. It seldom achieved more than a single story, with a steep roof that slanted backward from the ridge pole, covering the lean-to. The door was in the middle of the front, opening directly into the kitchen or living-room, and without the shelter of a porch. The windows were few, and glazed with small panes. Before the door was a flat stone, in place of steps.

This entire absence of architectural effects in the early New England house was not so much the expression of the English Puritan character (although undoubtedly it affected that of their descendants, as it was a revelation of the poverty of their resources and the qualities of the climate. Having to contend with a niggarly soil, short, scorching summers, and long arctic winters, at the same time defending themselves from Indian attacks, left little time to think of anything beyond the primary wants of existence. Whatever pause came to them was required by their religion, in the cultivation of that self-abnegation which their circumstances called for.

The interior of the early New England homestead was in keeping with the exterior. The kitchen was the only habitable room in winter. Whatever of comfort it afforded was imparted by the immense fireplace and chimney, where during the winter months the hardwood logs were kept burning continually. When bed-time came the huge "back-log" was heaped over with coals and covered with ashes, as carefully as a steamer's engineer banks his fires when his ship is at rest. If it chanced that a heavy snow storm sifted an avalanche of snow down the wide chimney during the night, so much the worse for the early riser next morning. To the New Englander fire-worship should have seemed perfectly logical.

In commending the ventilation afforded by colonial "interiors," where the "great room" of a mansion might have nine doors, and a chimney twelve feet square at its foundation, we must not forget the frequency of deaths by consumption, and the sufferings of rheumatic old age, consequent upon the unavoidable draughts. Our colonial ancestors usually had several wives in the graveyard, and a good many of the fathers died before their time.

Notwithstanding these drawbacks, as time wore on the homes of New England gradually acquired, and by very reason of the difficulties to be overcome, more of the real comforts of life than those of the more western or more southern colonies. All the exigencies of Indian wars, hard winters and hot summers were provided for.

Brick and stone houses were erected with particular care for their solidity. Wooden buildings were constructed with double walls interlined with brick, to resist Indian bullets. Hidden closets and under-ground passages were in some instances provided, with a view to the safety of the family in case of attack. Attached to the kitchen was the wood-house in which the year's store of cordwood was neatly piled. Close by, and often under its roof, was the well which supplied the household with water. In the tightly-walled and capacious cellar were bins for fruit and vegetables. Somewhere off the kitchen were the pantry and dairy.

In supplying these numerous needs, colonial domestic architecture became picturesque by its very homeliness. The better class of houses in the early part of the eighteenth century were still severely plain on the exterior, with steep roofs, giving if needed, extra rooms in the attic, which usually however, was used for storing unused articles, and relics.

The increase of wealth, and the residence among the colonists of royal appointees, led gradually to the introduction of more varied and attractive styles. Porches, pediments, balustraded roofs, projecting wings and gables, marked the later colonial dwellings. But the stately, columned manor house of New York and Virginia was never a feature of New England.

If we would study the life of the first half-dozen generations of Americans in this quarter of the United States, we must look for it at the fireside, in the library, or in the halls of old Harvard, founded in 1638, when Massachusetts Colony was but eighteen years old. The founders turned from heavy toil and savage warfare to religion, philosophy, poetry, and patriotism, and were ever busy in "building better than they knew," the only really free republic on earth. They could afford to wait for results.

* * *

When we speak of colonial architecture, it should be re-

membered that the several colonies represented separate nationalities, and that America, like Rome, drew to itself many peoples. Without the wealth of Rome, it adopted that which was most convenient, rather than that which was artistic. It will be well for us when our day of luxury is at hand, if we observe, as did the Greeks, simplicity with refinement.

THE ELDORADO SCHOOL BUILDING, STOCKTON, CAL.

WE PUBLISH in this issue, accounts of three recently erected Public School Buildings in this State. During the last five years more attention has been paid to the construction of this class of building than ever before, and the work has resolved itself into various specialties, the architect assuming the general responsibility for the exterior design and planning the interior to best meet the requirements.

The matter of "lighting" has been one under discussion for several years and has resulted in the general acceptance of strong light from one side of class room only. Recent opinion also proves "green" in place of "black" for the boards in the room. Perhaps of all specialties, the one commanding the most thought and attention at present time is the matter of proper "warming and ventilating" and thorough sanitation of this class of buildings. Every thinking man will at once realize the importance of pure air in these crowded class rooms and how to obtain this at a nominal expense has engaged the thoughts of leading engineers and mechanics throughout the world.

From the above it would appear that one duty of the architect, at the present time, is to give his clients the benefit of whatever he may know or possess and also (by being well informed as to the various specialties) by combining the knowledge of several, give his clients a completed structure possessing all the modern features that make a building perfect.

In the matter of "plumbing" and "sanitation" work a like advancement has been made and the toilet rooms in these buildings are as free from disagreeable odors as are our parlors in our private homes.

A recent report from the Board of Health, on the "heating, ventilating and sanitary system" in the El Dorado School Building, Stockton, Cal., in connection with this subject, will be of interest.

EL DORADO SCHOOL.—W. W. OATES, ARCHITECT.
Warmed and ventilated by Morgan & Co.

STOCKTON, CAL., Dec. 23, 1898.

To the Honorable Board of Education of the City of Stockton.

LADIES AND GENTLEMEN:—The request of your Honorable Body that the Board of Health examine the heating and ventilating system and water flush closet apparatus inserted in the El Dorado School Building, was referred by said Board to the Committee on Public Buildings, consisting of the undersigned and Dr. Fitzgerald.

Accompanied by Dr. Fitzgerald and Health Office Ruggles, I have made a close inspection of the El Dorado School Building as regards its sanitary condition, its warming and ventilating system, lighting, etc.

The building seems well adapted to its requirements as to room and arrangement. The water closets and urinals are the most perfect system that could be possibly had, being free from all possible odor and so ventilated as to make it impossible that any air or odor from them can enter any

other part of the building. The closets and urinals are arranged with automatic flushes that can be regulated to flush any number of times per hour desired.

The heating and ventilation are accomplished by a most perfect system, by which a large amount of fresh air is warmed but not overheated, and admitted into the rooms in such a manner as not to produce a draught, an amount of impure air equal in volume to the pure air admitted being withdrawn from the floor where the impure air is most apt to be found.

By the most careful tests we found that the entire air of the room was changed at least 7½ times an hour, keeping the air fresh and pure and giving the room a fresh, spring-like feeling. A test for carbonic acid gas the most contaminating element to be found in crowded and poorly ventilated rooms, gave as a result an amount of said gas scarcely above that of the out door air, thus proving beyond a doubt that the system is a perfect success and that the children who attend the El Dorado School have nothing to fear from a cold or vitiated atmosphere. Contageous disease in such a school if once introduced, would not have the tendency to spread, as in those without these very excellent sanitary advantages. The children would average better scholars and brighter students and make better citizens, when grown to manhood or womanhood, than will those attending schools unprovided with equal sanitary appliances.

During the past school year Drs. Ruggles, Fitzgerald and myself have visited many of the school buildings of this City to investigate and if possible suggest improvements in their sanitary condition.

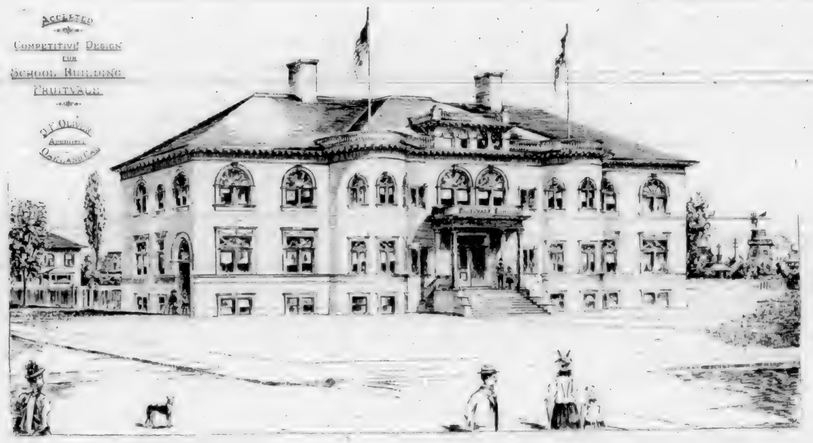
We found in most buildings, the heating and ventilating were about as imperfect as possible. Many of the rooms crowded with from 40 to 55 children are warmed with stoves and have no means of ventilation provided, excepting such as is most likely to remove the warm air and admit the cold air in such a manner as to give draughts affecting the children within the immediate vicinity. Thus some of the children are too warm, some too cold and all with cold feet and hot heads. To fully appreciate the condition of most of our schools and to understand what they should be, one should read a paper which I carefully prepared and read before the San Joaquin County Medical Society in March 1895, after having visited most of the school buildings in company of the School Board.

With due appreciation of its importance, this report is respectfully submitted.

(Signed) S. B. Davis, M. D.
Chairman Com. on Public Buildings of Board of Health.

We have carefully read the above report submitted by Mr. Davis, Chairman of the Committee on Public Buildings, and heartily endorse it and concur in all its suggestions and recommendations.

(Signed) William E. Gibbons, M. D.; W. W. Fitzgerald, M. D.; S. N. Cross, M. D.; C. A. Ruggles, M. D.

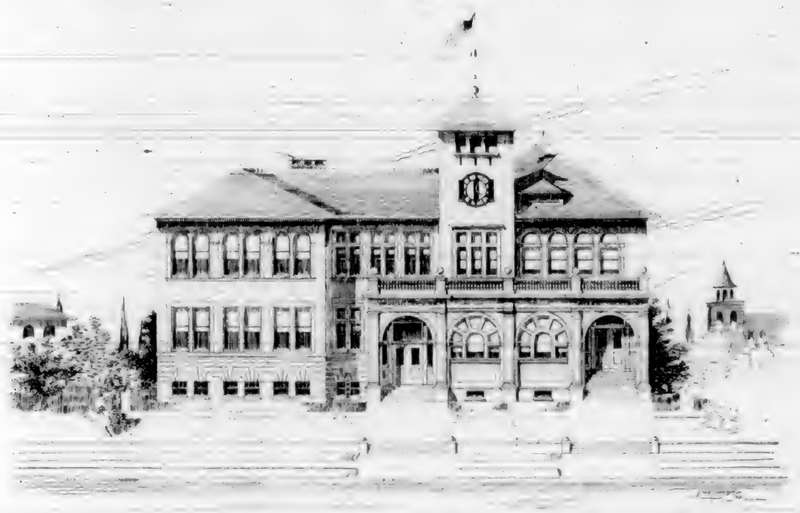


THE ACOUSTIC PROPERTIES OF BRICK AND TERRA COTTA.

ALTHOUGH a great deal is known concerning the acoustic properties of wood, and of various metals used in construction, it is not a little remarkable that analogous properties in brick, tile, faience and terra cotta should be so little understood. This ignorance arises in great measure from the circumstance that both physicists and architects have contented themselves hitherto by considering acoustics from the point of view of the shape of interiors of buildings only. Or, in a secondary way, the materials lining the walls, and such as may be regarded as capable of reinforcing sound.

have received some attention. As a matter of fact, in many large buildings such things as resonant boards, reflectors, and match-board dados are quite subservient to the chief materials of construction as often laid bare in the walls of the higher part of the building inside. Again, we commonly find that at least some considerable part of the walls is lined with clay goods in some shape, such as tiles, glazed panels, and the like.

Everybody who has studied the acoustics of large buildings admits that the chief enemy to deal with is reflection of sound, which produces echoes and general uncertainty in hearing, no matter whether the lecturer be strong or weak in voice. Consequently we find that when, the building having been newly put up, the acoustic properties are bad, the first thing the architect flies to is that which he understands best, namely wood. During the present century utilized for the performance of music, we commonly find that attempts are made to lessen it by using drapery. An interior, designed by the architect to show off its noble proportions, or enriched by the frescoes of some Royal Academician, or embellished by beautiful marble panelling and mouldings, is thus ruined. For the right interpretation and appreciation of orchestral music it is absolutely essential to stifle echo at its birth. We should hear only that which proceeds direct from the executants to our ears, and the harmony should not be disturbed by the reverberation of the musical notes from side to side of the building. It is to be noted that intensity of the sound is not the leading factor in such a case as this. If a little water be violently thrown on to the surface of a smooth-faced wall it glances off, and the same thing will happen with a large quantity; on the other hand, if either the large or the small quantity be



High School and Library—San Rafael, Cal.

there has been quite a boom in that material, though we ought not to torget the metal reflector placed over the pulpit in St. Paul's Cathedral, which has been so successful in that particular case.

Yet, but a little consideration of some elementary problem in physics suffices to show that wood is by no means always desirable, or can be in any way successful, in the interior of many edifices. Wood is a great reinforcer of sound by reason of its elasticity, but that very property is disastrous in certain interiors.

Sound is most perfectly reflected from smooth surfaces, and when acoustics of the interior are bad owing to form of construction, and reflection is wanted, what could be better than glazed surfaces? Large glazed tiles, or faience work in panels, are most admirably adapted for the purpose, but how often do architects use them for their acoustic properties. On the other hand, when owing to interior shape of the building reflection from the walls is not wanted, where can any better material than porous clay-goods be found? When echo is too manifest, and the building is largely thrown on to a wall having a porous surface much in either case will soak in. And so it is with sound. If the grand interior which we have just been alluding to were constructed of porous clay-goods, the architect, the Royal Academician, and the embellisher still have their chance, and the drapery could be done without.

We do not ask modern artists, with all their fanatic and æsthetic ideas, to succumb to science or to pander to the worker in clay, but we are perfectly justified in reminding them that many of the ancient works of art which they all but worship are the work of clayworkers. They seem to forget this. Their ideas are confined (like the latest craze in art) in straight lines and angles; they have set up for themselves a certain number of cast-iron regulators, which may be likened unto the by-laws of a county Council. They can see art in ancient clay-work, but not in modern—that is because they have moulded themselves into that train of thought. Once get rid of that, and we can furnish both the artist and the architect with materials such as the ancients had in the interior of their buildings, which were then, and are now, in many respects acoustically perfect, which were then, and are now (in ancient structures) admired for their artistic beauty.

We have said that clay work is often superior to wood work for acoustic purposes; we will substantiate that point by referring more particularly to the merits and defects of both for the uses named. Let us begin with wood. Here we have a material with a fibre; we cannot get wood without fibre. Fibres act as wires and are conductors of sound like the latter. Consequently if sound strikes a match-board surface, much of it is immediately given a biased direction in the direction of the fibres. This bias is useful when the wood is to act as a species of sounding-board, but when echoes are to be minimized (as is more frequently the case) it is to be deprecated. Wood with knots is better as retarding the propagation of sound within the fibres, than is wood with straight fibres.

But for sound-proof walls, if wood is to be employed, it has to be cut in such a way as to make the general construction somewhat expensive. Now all this can be done away with if such a material as terra-cotta be employed. The velocity of sound in a body is a fair index of the use of that body for acoustic purposes. As would naturally be supposed, the velocity is not so great in loosely compacted materials as in those more closely aggregated. If the object in the wall be to stop sound from going through it, then it might be lined with exceedingly porous terra-cotta. If, on the other hand, the surface is to be of a neutral character, terra-cotta with a "semi-vitreous" face is more suitably employed. If, as in many small country churches, the upper parts of the wall above the dado are to be left bare, the bricks showing should always have a fairly hard surface so as not to soak in the sound too much. But, for a church having a central dome, underneath the centre of which the pulpit is to be usually placed, the interior of the dome if left bare (commonly the case with small churches) should be made of strong rubbers, and we should not object to the light porous kieselguhr brick for such a purpose.

It may be taken for granted that the velocity of sound is greatest in hard brick, such as ruabon reds, metalline, hard blues, firebrick, and stocks, and least in gaults, ordinary reds, and sand rubbers. To recapitulate, therefore, the former class should be employed for conducting and reinforcing sound, and the latter for the reverse—as sound-proof materials, and in stifling echoes.

Majolica and faience, when used in broad and flat surfaces, must increase echo, and when used very thin must be fairly resonant; when much broken up, however, either by frequent jointing, or when projecting in pattern, sunk or raised, its effects must be mainly of a neutral character.

The problem of the obnoxious party wall may be readily solved by using soft brick jointed with good mortar, taking that the wall is solid throughout; the difficulty of noise in flats from one floor to the other might be very considerably done away with by using majolica and faience ceiling mouldings for all angles, and by constructing the face of the wall of the porous brickwork, faced by plaster of a more or less porous character. Sound reflectors for public building, not for reinforcement of sound, but for giving it direction, would be more suitable when of porous earthenware, and this would be much less unsightly than metal reflectors and tubes.

In short, the capabilities of clay goods in the directions indicated for assisting and modifying sound, are much more worthy the attention of architects than has hitherto been thought: less worthy materials have had a long trial, now give "brick, tile and terra cotta" a better chance.—*Clay Record.*

ILLUSTRATIONS.

The management of this journal desires to extend a cordial invitation to all architects on this coast and elsewhere to contribute designs for publication.

Drawings should be made with perfectly black lines on a smooth white surface. Good tracings, if made with black ink, answer the purpose.

The designs selected will be published without charge. All drawings, whether accepted or not, will be returned to their authors, who must bear express charges both ways.

VALUABLE INFORMATION CULLED FROM OUR EXCHANGES.

THE results of some experiments to ascertain the most effective material for checking the percolation of water through brick or stonework are given by Mr. A. W. Hale in a recent number of the Engineering and Mining Journal. The investigation was mainly carried out in connection with the new Croton aqueduct of New York, and the substances employed in the experiments were numerous and varied. It was found that Portland cement gave the best results, and that the hydro-carbons, which are commonly regarded as suitable materials for rendering brick or stone impervious to water, oxidized by exposure to air and gradually disappeared. It was also found that a brick was rendered im-

pervious to water by cement more rapidly when the cement was applied as a wash by means of a brush than when applied with a trowel in the usual manner. A brick which had been treated with four cement washes was found at the expiration of two months to be quite impervious to water, even under a pressure of two hundred pounds per square inch.

IF Andrew Carnegie has mastered the art of making money, he has been equally conspicuous in a discreet but munificent manner of giving it away. In the course of the last twenty-five years he is credited with giving away $17,000,000 for public purposes. He is evidently a robust believer in educating the people, and in the forces for good that are the dynamics of intelligence. His benefactions to libraries have been ungrudging and wide-spread. Among nineteen of these the iron king has distributed not less than $5,483,000, ranging from $8000 to $3,000,000. These are big figures, and are but a portion of what has really been a massive benefaction to human good. Nor has the water all gone over the dam.—*The Age of Steel.*

A FARM of three hundred and fifty acres is being worked by electric power in the state of New York. There are two waterfalls on the farm, and these furnish the power for operating the electric plant. One motor, of ten horse-power, operates a hay cutting machine, another a threshing machine, and another a circular saw for cutting logs. The dwelling house is well lighted and is also heated by electricity. Cooking is done by electricity and churns, milk separators and other dairy appliances are operated by the same agency. The power is also used for lighting barns and other buildings. As more power is generated than is necessary, the surplus is rented to two knitting factories. This is claimed to be one of the most complete and unique installations ever yet made on a farm, and its success will probably lead to others of its kind, with like facilities of water power being on equal terms.—*The Age of Steel.*

AT a meeting of the Franklin Institute long since past Prof. Edward J. Houston speaks of the physiological effects of alternating currents of high frequency. He divides electric discharges into three varieties. First, galvanic currents; second, alternating current, commonly called faradic; and third, electro statis discharges which may be called Franklinic currents. It seems as though Franklinic and faradic currents produce about the same effect upon the muscles. Another fact is equally true that as the rapidity of alternation increases, the severity of the physiological effects decreases until when enormously high frequencies are reached, the discharges become harmless. These facts have been demonstrated by Dr. Tatum for comparatively high frequencies and by Nikola Tesla for enormously high frequencies. To quote from Tesla, we conclude with the following: "I have found that by using the ordinary low frequencies the physiological effects of the current required to maintain at a certain degree of brightness a tube four feet long provided at the ends with outside and inside condenser coatings is so powerful that I think it might produce serious injuries to those not accustomed to such shocks; whereas with 20,000 alternations per second the tube may be maintained at the same degree of brightness without any effect being felt."—*The Electrical Age.*

NOTICE OF MEETINGS.

San Francisco Chapter, American Institute of Architects, meets second Friday of each month at 408 California street, at 4 p. m.

Seth Babson, Pres. — H. A. Schultz, Vice-Pres.
J. W. Reid, Sec. — John M. Curtis, Treas.

Southern California Chapter American Institute of Architects, meets first Wednesday of each month at 114 Spring street, Los Angeles, Cal.

A. B. Benton, Pres. — Arthur B. Benton, Vice-Pres.
John P. Krempel, Sec't. — August Wackerbarth, Treas.

Washington Chapter American Institute of Architects, regular meetings at 8 o'clock P. M., the first Friday of each month, except July and August.

Wm. E. Boone, Pres. — Jas. G. Hill, Vice-Pres.
Charles W. Saunders, Sec. — W. J. Marsh, Treas.

Association of Architects of Arizona, meetings held at Phoenix, Arizona.

D. W. Millard, Pres. — T. H. Maddox, Vice-Pres.
W. R. Norton, Sec. and Treas.

Technical Society of the Pacific Coast, meets first Friday of each month at Academy of Sciences Building.

Geo. W. Percy, Pres. — W. F. C. Hasson, Vice-Pres.
Otto Von Geldern, Sec. — Edward T. Schild, Treas.

Master Plumbers' Association, meets every first and third Friday of each month at the Flood Building.

Jas. E. Britt, Pres. — J. L. E. Firman, Sec.

Builders' Exchange, Directors meet first Friday in each month at Mission and New Montgomery.

S. H. Kent, Pres. — Jas. A. Wilson, Sec.

Masons' and Builders' Association, meet first Friday evening of each month.

Adam Beck, Pres. — M. V. Brady, Sec.

THE STATES AGAINST THE TRUSTS.

WHILE it is unfortunate, it was inevitable, that the anti-trust agitation should develop a difference of views as to where the proper power is lodged for the suppression of the trusts. The dual character of our government affords a basis for honest differences on this point, especially as to many of the suggested methods of heroic procedure against the evil. Hence it happens that we find the opinion of the Attorney-General of the United States opposed to that of Justice Harlan, of the United States Supreme Court, on the general proposition that the Federal Government is competent to deal with the trusts. The Attorney-General holds, in effect, that domestic corporations must be controlled by the States; while in his dissent from the opinion of the Supreme Court in the Sugar Trust case, Justic Harlan expressed himself in this wise:

"We have before us the case of a combination which absolutely controls, or may, at its discretion, control, the price of all the refined sugar in this country. Suppose another combination, organized for private gain and to control prices, should obtain possession of all the large flour mills in the United States; another of all the grain elevators; another of all the oil territory; another of all the salt-producing regions; another of all the cotton mills, and another of all the great establishments for slaughtering animals and the preparation of meats. What power is competent to protect the people of the United States against such dangers except a national power—one that is capable of exerting its sovereign ruthority throughout every part of the territory and over all the people of the nation?"

It is not to be denied, to be sure, that Congress may not in a variety of ways hamper and discourage the trust movement—as, for instance, by the enactment of a law placing all foreign merchandise competitive with trust products on the free list; but as against congressional power of extirpation by taxation, or by means quite as drastic and even more direct, constitutional questions are interposed in number.

Inasmuch as delay favors the trusts; gives strength to their commercial and financial standing, and opportunity and encouragement for their further formation—it is evident that if the evil is to be checked before it has run its full course, the States must attack it upon their own account, without reference to anything the Federal Government may or may not do in the fulness of time.

This is the Texas view of the situation, and it is a sensible and business-like one. Governor Sayres of that State has determined, according to newspaper reports, to call a conference of the Governors and Attorney-Generals of the Southern and Western States for the purpose of "discussing and agreeing upon a concerted and effective policy and line of legislation against trusts and monopolies." This conference will recommend to the Legislature of the several States represented in it such measure as will, if enacted, insure uniform and effective laws for trust suppression.

There is no doubt that if such a programme as this is followed by fifteen or twenty, or more, of the Southern and Western States the subjugation of the trusts will be assured. But can such concert of action be had? Still, the plan is a good one, even if it cannot be carried out—and it is certainly worth the trying.—*The Age of Steel.*

TALKING ALONG A RAY OF LIGHT.

IT SEEMS very much like a fairy tale to hear of a public exhibition being given showing how human intelligence can be transmitted along a beam of light. At the Electrical Exhibition, on Saturday afternoon, May 13th, the radiophone was shown in operation. This is an instrument of such construction that by means of a search light beam, speech can be transmitted a distance of seventy-five yards and heard with distinct enunciation. The property of selenium makes it immediately susceptible to the influence of light so that if used in conjunction with some variable light producing apparatus a telephone in circuit with it will give issuance to sounds in perfect harmony with these optical changes. A system of this kind can truly be called wireless telephony thus giving prominence to this latest exposition as the first in the world's history in which telegraphing and telephoning was carried on without a visible intervening medium between the transmitter and receiver. We remember in the fables of the Arabian Nights of the magic eye piece by means of which one of the characters delineated there was able to see the actions and motions of his friends though miles away from them. We have practically reached that state of ideal development, for at this present hour it is possible to send sketches over the wire through a distance of hundreds of miles, to send speech and signals through the ethereal atmosphere without employing the familiar means hitherto in use. Tesla's idea of transmitting power in vast quantities without wires at a distance far above the upper strata of clouds is one which may receive considerable attention in the near future. Within the last fifty years Americans have begun to invent and apply the forces of nature for many utilitarian purposes. If progress keeps up at the rate indicated there is much truth in the statement "that the marvels of the times have not yet appeared" for it seems very likely that many of our fondest delusions will be shattered by scientific successes which may strike out from Funk & Wagnall's dictionary the word "imposible." The radiophone represents an old principle through a new construction, but selenium, the metal utilized, seems to be permanently associated with all experiments that lead us to hope that images and speech will some day be transmitted commercially without wires. In our efforts to reach a higher efficiency in mechanical and commercial operations we are not over-reaching ourselves in directing investigations along such a channel of inquiry. The wireless telegraph system has come to stay. Why not wireless telephony?—*The Electrical Age.*

NOTE.

It Pleases us to notice the return to this city of Mr. M. S. James, agent of the J. L. Mott Iron Works, whose office in San Francisco is in the Flood Building. This firm has agencies in all the large cities of the United States, and furnishes the latest improvements in plumbing to builders throughout the country. Mr. James is a genial gentleman, and all around, up-to-date man. Call on him.

NEW YORK SURPRISED HIM.

A YOUNG Frenchman, wealthy, educated, and of an investigating turn of mind, departed for home a few days ago, taking with him some remarkable impressions of New York. He spent two weeks in this city, and, having some excellent letters of introduction, he met many persons well qualified to show him the sights of the American metropolis. Although an experienced traveler in European lands, this young Frenchman had never before been in the United States, and he frankly admitted that objects were presented to his view here such as he never saw before. Being impressionable, he naturally fell a victim to the irrepressible New York practical joker.

The tall office buildings astonished this visitor, and after luncheon one day on the thirty-sixth floor (as he believed) of one of them, he readily swallowed the yarn that vegetables and poultry were raised on the roof, because it would cost too much to get them at the markets.

While riding up Broadway with a waggish friend a few days before he went home, he noticed for the first time a slender thread of steam curling up from a manhole. "What is that?" he asked.

"Oh, that is one of the vents of the public radiator," was the reply.

"Public radiator," exclaimed the Frenchman. "You don't mean to tell that the streets here are heated by steam?"

"Certainly, in cold weather," was the unblushing answer. "Don't you feel warm and comfortable?"

"Indeed, I do," responded the Frenchman, enthusiastically. "But I never heard of such a thing as heating the streets of a great city. Well, well, New York certainly does beat the world."—*Heating and Ventilating*.

HYDRAULIC MORTAR.

CEMENT and mortar tests have been so extensively made and discussed that the subject may seem almost exhausted, but the value of such tests depends so much upon the manner in which they are conducted and investigated that a study as scientific as that made by M. Feret, the head of the laboratory of the Ponts et Chaussees at Boulogne, and published in the Bulletin de la Societe d'Encouragement demands recognition.

M. Feret first describes and tabulates the extensive series of tests for resistance to tension, compression, piercing, and shearing which were made in the laboratory under his charge, the same Portland cement being used in all cases, in connection with various kinds of natural and artificial sands, the intention being to investigate rather the physical properties of various mixtures than the comparative merits of different cements. The results are given in tabular form, and also plotted in curves, showing graphically the general behavior of the materials, after which the effect of variations in a series of test samples is discussed.

Attention is called to the fact that widely different results may be obtained from the same material, according to the manner in which the tests are made, and emphasis is strongly laid upon the point that tests are not comparable unless they have been made in the same manner.

In tests for flexure, for instance, the size of the specimen of great importance, since the distance of the outer and more resistant portion from the neutral axis has a great influence upon the result, and in general the greatest resistance of any specimen is found in that portion nearest the exterior. An unequal distribution of stresses must, therefore, appear in tension tests as well as in those for flexure, and this equality is still greater when the mixture is not perfectly homogeneous.

According to the theory of resistance of materials, tests by flexure and by tension should lead to the same ultimate strength, but deductions based upon materials of supposedly perfect elasticity do not hold good for mortars, especially as the point of rupture is approached. M. Durand-Claye has shown that the resistance deduced from flexure tests is almost double that obtained from direct tension, and the tests of M. Feret bear out the fact that there is a definite ratio between the two resistances—namely, the resistance by flexure is to that by tension as 1.89 to 1, or, in round numbers, as 2 to 1.

Similar relations were deduced between the resistance to compression and to shearing and punching, a constant and proportional ratio being found. There does not appear, however, to be any such proportionality existing between the results obtained by tension and by compression tests, and two different mortars having the same resistance under compression may show very different results in tension. As a result of much experience deduced from many tests, M. Feret states that he believes the test by compression gives the real measure of the coherence of a mortar more nearly than does a tension test. In all cases the compression tests gave more uniform and consistent results, both for large and small specimens and for various conditions of homogeneity.

The most important part of M. Feret's paper, however, is that relating to the physical constitution of a hydraulic mortar, especially with regard to the size of ultimate particles of the materials employed, and to the thoroughness of the admixture.

For a fine sand the resistance to crushing is much greater than for a coarse sand, the proportion of sand to cement being the same in both cases. A tabulated series of tests, using a constant quantity of cement and sand, but with different proportions of fine and coarse sand, showed that the resistance to compression was two and one-half times greater with find sand than with coarse, and corresponding variations appeared with the other mixtures.

An approximate measure of the nature of a mortar in this respect may be obtained by determining the density, or, as M. Feret calls it, the "compactness," of the mixture, since this bears a relation to the proportion of voids between the particles, which doubtless plays an important part in the strength of the mortar. In plotting the results of the tests made with sands of various degrees of fineness M. Feret uses the ingenious form of triangular pyramid adopted by Professor Thurston in his investigation of the strength of various bronzes, and in this manner the results are shown with a clearness not otherwise possible. Similar diagrams are given for mixtures of sand, cement and pulvarized slag, and the paper closes with data as to the effect of the addition of a proportion of puzzolana to cement and sand, especially for hydaaulic mortars which are to be exposed to the action of sea-water.—*Clay Record*.

DUNHAM, CARRIGAN & HAYDEN CO.

17 and 19 BEALE ST., San Francisco Cal.

WE show here an illustration of our **AMERICAN SLIDING DOOR HANGER** for which we claim unusual advantages, great saving in time and expense, and superior excellence in operation, together with the following features not obtained or claimed in other hangers.

TRACKLESS—We obviate the use of a track above or below, and the special framing necessary where a track is used.

NO WHEELS—There are no wheels to bind by reason of warped or sagging track. The movement is perfectly PARALLEL and insures against binding.

NOISELESS—The operation is noiseless and extremely easy.

DOORS EASILY ADJUSTED—The door can be readily adjusted plumb, raised or lowered by drawing them into the opening which gives easy access to the adjusting screws.

QUICKLY PUT UP—The Hangers can be put up in one-third the time required for overhead hangers.

SUBSTANTIAL—The parts are made to carry three times the weight of doors of the sizes given.

ONE PACKAGE—We pack the Hangers fully assembled and ready to attach, in ONE package, including all bolts and screws necessary.

☞ *See a full size working model at our store.*

FACTS ABOUT PAINTS.

PHŒNIX

The best paint is made of White Lead, Zinc and Linseed Oil.

PHOENIX PURE PAINT is made of these materials only.

PURE

To make perfect paint these materials must be finely ground and thoroughly mixed with heavy machinery.

PHOENIX PURE PAINT is made in that way.

During the past five years PHOENIX PURE PAINT has been the one most generally specified by Architects on the Pacific Coast.

PAINT

It is guaranteed absolutely pure and satisfactory on the building or we will replace it with any material the architect may select.

DURESCO

The New Wall finish or Washable Water Color.

Petrifies on the wall and will not crack or chip off.

Damp Walls do not affect it.

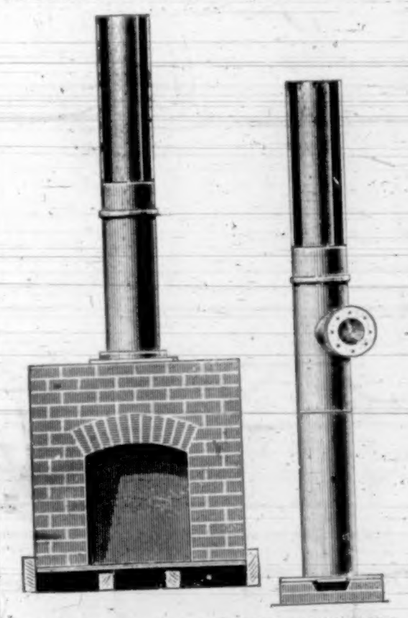
Can be washed any number of times and will not change color.

It strengthens the wall and prevents crumbling.

The strongest, most brilliant and most durable Wall finish made.

MANUFACTURED BY

W. P. FULLER & CO.



CLAWSON'S PATENT CHIMNEY.

L. E. CLAWSON & CO.

1340 MARKET STREET. SAN FRANCISCO.

TELEPHONE SOUTH 257.

CLAWSON'S PATENT HOOD OR THROAT AND ARCH-BAR COMBINED.

The arch-bar forms a bond for arch in brick work. The hood being bolted on the arch-bar, forms a bond from brick work to mantel.

The throat is one solid piece, having lugs admitting three (3) inches adjustment, to suit depth of mantel.

This hood makes the bricklayer conform with mantel man's work, and guarantees you a safe chimney with a perfect draught.

Clawson's Patent Hoods, Thimbles and Chimneys, comply with the new Fire Ordinance.

See CLAWSON'S LIVE VENTILATOR. It is as much better than a dead one, as a live man is of a dead man.

Price, $2.50 for any size from 18 to 26 inches.

☞Send for illustrated circular.

CLAWSON'S PATENT THIMBLE.

IF YOU SPECIFY
